THE science of sanitation is generally believed to be a recent one. The germ theory of disease has been developed and verified within the memory of living persons, and the important researches of Pasteur, Lister, and Koch in the latter part of the nineteenth century created a new science — bacteriology. These discoveries so enriched the field of preventive medicine, hygiene, and sanitation that the results of disease prevention have been greater in late years than ever before during the whole progress of mankind. Recent as are these attainments, however, the science of sanitation itself goes back into the dawn of history. It goes back to those magnificent civilizations of five thousand and more years ago, those civilizations forgotten so long and revealed only so recently. Its traces have been found in Assyria and Babylonia, Egypt and Crete, Greece and Rome; its story is the romance of sanitary science.

Beginnings of Medical Science

Medical science began with the earliest civilization and was thought by primitive people to have been the gift of the gods. Sanitation is, broadly speaking, a branch of medical science, but whereas medicine has aimed to cure diseases, the function of sanitation is to prevent their spread. The terms "public hygiene" and "sanitation" are practically synonymous, but hygiene by itself is a personal matter, and sanitation deals with the environment. Dissemination of disease is prevented by the safe disposal of human wastes, by obtaining an adequate and pure water supply, by control of the sick, and by the general cleanliness of man and his environment. In the beginning of things medicine was interwoven with magic, and disease was believed to be due to the evil influence of displeased demons. In spite of these notions, ancient peoples seemed to recognize the value of sanitation and their sanitary appliances were surprisingly similar to those of to-day.

THE HERITAGE OF CIVILIZATION IN DISEASE PREVENTION

The history of sanitation repeats itself. Having emerged from the darkness of the centuries following the decline of Rome, we now face the sunrise with its dazzling achievements in sanitary science. We have an honorable heritage and shall give to the world monuments as enduring in the glory of disease prevention as were those of the peoples of the past. To limit sickness to the minimum, to prolong life to the maximum, and reduce the unnecessary death rate of modern times—after all, that will be the real romance of sanitary science.

It is complimentary both to the present and to that past to call these devices "modern."

History begins about six thousand years ago. The earliest known civilization of the world was that of the ancient Sumerians, who inhabited the broad valley north of the Persian Gulf between the Tigris and Euphrates rivers, now called Mesopotamia. Recent excavations have shown that the dwellings of these people were pro-

vided with drains and sanitary conveniences. Since the country was flat and the soil sandy, the work was individual and not a community enterprise. No attempt was made to build sewers for these municipalities of six thousand years ago, but each householder constructed his own drain and cesspool in a manner similar to the Arabian of the present day. The Sumerians were succeeded by the Chaldean-Babylonian and Assyrian Empires, whose great capitols were at Babylon and Nineveh. Here, the whole city was sewered and also supplied with water brought from long distances through open channels. When it is considered that the city of London had no sewerage system until the eighteenth century after Christ, we must pause in admiration of these cities which date some twenty centuries before Christ.

Public Hygiene in Ancient Egypt

Another great civilization of ancient times was that which flourished in the valley of the Nile some three thousand years before Christ. Here are the land of the greatest structures ever built by man, the pyramids, and the world's most imposing temple, Karnak. We owe our knowledge of Egyptian customs to the patient work of the archaeologists and also to the writings of the Greek historian, Herodotus. The Egyptians worshiped the scarabaeus, or dung beetle, possibly recognizing its scavenging powers and its contribution to sanitation. Herodotus tells us that the Egyptians kept their houses clean, bathed frequently, and attempted to obtain un-

polluted water. Near the pyramids of Gizeh, which were built about 3000 B. C., is the well of Joseph. This well is excavated through solid rock to a depth of 297 feet and illustrates the efforts that the Egyptians would undertake in order to obtain pure water. Public hygiene as practised in this ancient empire had great influence on the habits of people who followed.

be infected. They recognized the sanitary significance of bathing, as is well illustrated by the biblical story of Namaan. In order to avoid infection from foods, they cooked all meats and vegetables and abstained from using certain meats which were considered unclean. They also had a code for social hygiene, a subject that has a sanitary significance as well as a moral aspect.

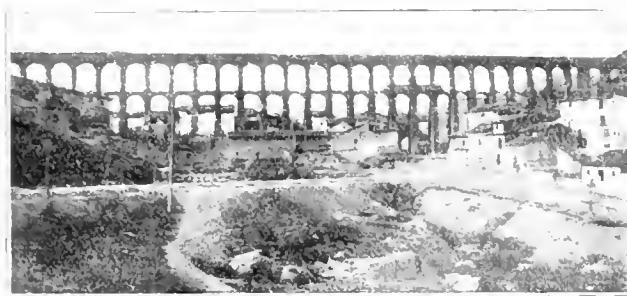

Aqua Claudia, Rome, the work of the fourth Roman emperor, whose name it bears, and his predecessor, Caligula. This system had its intake about thirty-eight miles (Roman) above the city and united with the Aqua Anio Novus seven miles from Rome. Claudius gave the length at 45 miles in the inscription on the Porta Maggiore, by which the channel was carried across the Via Praenestina and the Via Labicana. The channel varied in size at different points on its course. The bridges were of masonry with a substructure of brick-faced concrete. (Photo, Alinari. Reproduced from the Encyclopaedia Britannica by courtesy of the publishers.)

Two other civilizations of importance in antiquity were the Phoenician and the Hebrew, which existed side by side between the Mediterranean Sea and the Arabian Desert in the lands now called Syria and Palestine. Trade was carried on between the Egyptians and Babylonians and the country served as a middle land for these other two great empires. Egyptian manuscripts show that these peoples existed about seventeen centuries before Christ. The ancient Hebrews were the real founders of public health. The laws of Moses (born about 1600 B. C.) contained many hygienic ordinances, most of which apply as well to-day as they did when they were first promulgated. The influence of Egypt is shown by this passage from the Bible: "And Moses was learned in all the wisdom of the Egyptians and was mighty in words and deeds" (Acts vii-22). He prescribed few, if any, remedies for disease, his treatment being (1) prevention, (2) sanitation, and (3) trust in Nature. The Hebrews isolated persons afflicted with syphilis or leprosy, and burnt all excreta and any articles which might

The city of Jerusalem was well sewered and had a good water supply. Previous to the eighth century before Christ the city had two aqueducts, one from the pools of Solomon and the other from the pools of Hezekiah, outside the city walls. In 727 B.C. King Hezekiah built a vast reservoir, called the pool of Siloam, near the gates of Jerusalem. The existing water supply was insufficient to fill it, so he constructed a tunnel through the solid rock of a hill behind the city. His workmen began at both ends and met accurately in the middle. The magnitude of this undertaking is apparent when it is considered that the work was done with hand tools of a more or less primitive type.

The most extensive and elaborate sanitary engineering of remote times was that which has been brought to light again on the island of Crete. The palace of Broad Knossus, which dates from about 2100 B.C., has an amazingly complete system of drainage. Shafts lead from the main conduits to the roof where rain water was collected and used to flush the drains. These pipes,

some of which are still there, were of terra-cotta, were about two and a half feet long, tapering from a diameter of six inches to one of four and grooved to fit other sections. The main drains were about a yard wide by half a yard deep and were lined with cement. They were supplied with manholes throughout. The whole palace was

Roman aqueduct at Segovia, Spain. This structure has a length of 2,400 feet and stands 102 feet at its highest span. In the two tiers of masonry there are 100 arches. (Photo, Laureat y Cia. Reproduced from the Encyclopaedia Britannica by courtesy of the publishers.)

equipped with bathrooms and latrines and the system remained incomparable for four milleniums.

Writing of this ancient palace of the sea kings of the House of Minos, Doctor Evans, the archaeologist, says: "From the open court to the east and the narrower area that flanks the inner section of the hall, the light pours in between the piers and columns just as it did of old. In cooler tones it steals into the little bath room behind. It dimly illuminates the painted spiral frieze above its white gypsum dado, and falls below on the small, terra cotta bathtub, standing much as it was left some three and a half milleniums back. The little bath bears a painted design of a character that marks the close of the great 'Palace Style.' By whom was it last used? By a queen, perhaps, and mother for some 'Hope of Minos'—a hope that failed."

The connection of Crete with Egypt was found near the wall of another bath room in the palace. Here was discovered the lid of an Egyptian alabastron bearing the cartouche of a king, evidently one of the Hyksos, or Shepherds who overran Egypt in 1675 B. C. A similar cartouche on the breast of the carved figure of a lion was found in ancient Bagdad and is now in the British Museum.

The Persians under Cyrus the Great eventually conquered the civilized world. They, too, owed much to the Egyptians for their sanitary knowledge. They revered rivers and would not permit of their defilement. Cyrus (559-529 B.C.) was a wise commander and always took provisions and drinking water from home on his campaigns. He had the water boiled, indicating that the therapeutic value of this process was known to the

ancients. In a conversation with his father, Cyrus is quoted as saying: "I have heard and seen that those states which seek for good health educate physicians, and that commanders take with them physicians for the sake of the soldiers. I, too, therefore, as soon as my present expeditions were intrusted to me, gave my attention to the subject and thought that I had with me very competent physicians." To which his father replied: "But these physicians, my son, of whom thou speakest, are like menders of torn garments, and thus, they cure those who have fallen sick. Thy chief anxiety should be to provide for health, for thou oughtest to take care to prevent the army from falling into sickness at all." Compare the military hygiene of Cyrus with that of our own country in the Spanish war; fortunately, the black record of 1898 has been honorably amended by the excellent sanitary conditions of our army in the war with Germany.

Other nations which had well developed civilizations in early times were the Chinese and Hindus. The Hindus had rules of hygiene, but public health was unknown in China, as it is at the present day. Medicine in China began about 2800 B.C. with a treatise by the Emperor Schin-Nung and the ancient Chinese knew of inoculation against smallpox. Their traditional policy of aloofness probably accounts for their lack of sanitary knowledge. The deepest wells of antiquity

Aqueduct of Roquefavour, Marseilles, built in the early nineteenth century. (Photo reproduced from the Encyclopaedia Britannica by courtesy of the publishers.)

were dug in China, however, and travellers tell of wells which are 1,500 feet deep and date from early times.

The Druids of ancient Britain, who were contemporary with Abraham and Jacob, remote an-

cestors of Moses, were skilled in medicine and are believed to have practised sanitation. In America the oldest evidence of sanitary science is given by the wells along the valley of the Mississippi, which are believed to have been built by primitive peoples many centuries before Christ. One in particular in the hills of Yucatan is worthy of

Pont du Gard, Nîmes (Nemusus). This structure rises to a height of 160 feet at its highest span. It consists of three tiers of arches. In the lowest tier are five arches having a span of sixty feet and one with a span of seventy-five feet. The second tier has eleven arches, each with a span of seventy-five feet. The upper tier consists of a series of thirty-five smaller arches which carried the *specus*. Among the existing ruins of this type of Roman structure, it has no equal for lightness and boldness of design. (Photo, Neurdein. Reproduced from the Encyclopaedia Britannica by courtesy of the publishers.)

mention because it is bored to a depth of 100 feet and then through a horizontal gallery 2,700 feet long before water is reached.

The Greeks recognized the benefits of preserving health and their temples were usually situated in groves, near springs, and soon became health resorts. Excavations at the ancient cities of Mycenae and Tiryns, which were founded in the fourteenth century before Christ, have revealed great bath rooms. In 625 B. C. an engineer named Eupalinus constructed a tunnel 4,200 feet long and eight feet square in order to supply water to the city of Athens. The first sanitary engineering for Rome and Carthage was probably performed by Greek engineers, as the designs of all are similar.

The fifth century B. C. is called the golden age in Greece. Contemporary with Herodotus and Thucydides in history, with Aeschylus, Sophocles, and Euripides in the drama, Pindar in poetry, and Aristophanes in wit, were Empedocles, the naturalist, and Hippocrates of Cos, the "Father of Medicine." Empedocles performed a sanitary service for his native city of Agrigentum by cutting down a hill, thus letting in the north wind and so ridding the city of the plague. He also accomplished a similar service for the neighboring city of Selinus by draining a marsh. Hippocrates clarified medical science by his attitude toward health and disease. He wrote three books on hygiene and sanitation among his other numer-

ous works. He advocated the boiling or filtering of all drinking water. The Hippocratic oath is still administered to graduates of medicine about to enter the practice of their profession. In 431 B. C. occurred the plague of Athens and the story of it by Thucydides is the first record of any European epidemic.

Greece was conquered by Alexander in 330 B.C. During the decline of Greece two other empires were developing, Carthage and Rome. The latter eventually conquered Carthage, Greece and the East in turn.

Carthage is famous in sanitary science for having the oldest known cisterns. They were eighteen in number, each 100 feet long and about 20 feet deep. Fortunately, they were not destroyed when the Romans razed the city in 146 B.C. Cisterns are also mentioned in the Bible in Proverbs v-15: "Drink waters out of thine own cistern and running water out of thine own well." Carthage had an aqueduct leading from the springs in the Zaghorn Mountains to the city, a distance of about thirty-seven miles.

Piscina Mirabilis at Baia, one of the *piscinae limariae* or filtration and settling tanks outside the city of Rome, a reservoir which is covered by a vaulted roof supported on forty-eight pillars and perforated to allow the escape of foul air. (Photo, Brogi. Reproduced from the Encyclopaedia Britannica by courtesy of the publishers.)

The Romans are notable for the grandeur of their engineering, and much of it was devoted to sanitation. The city had sewers as early as 800 B.C. In 735 B.C. was built the famous Cloaca Maxima, which is still in use to-day, 2,654 years

later. It is 12 feet high, 11 feet wide and is lined with cement. Every Roman street had its lateral sewer diminishing in size as the distance from the main sewer increased. Each house was connected with the sewer, but as the drainage system did not extend above the first story and many of the houses were lofty, the inhabitants adopted the unpleasant system of throwing excreta from their windows into the public streets to the detri-

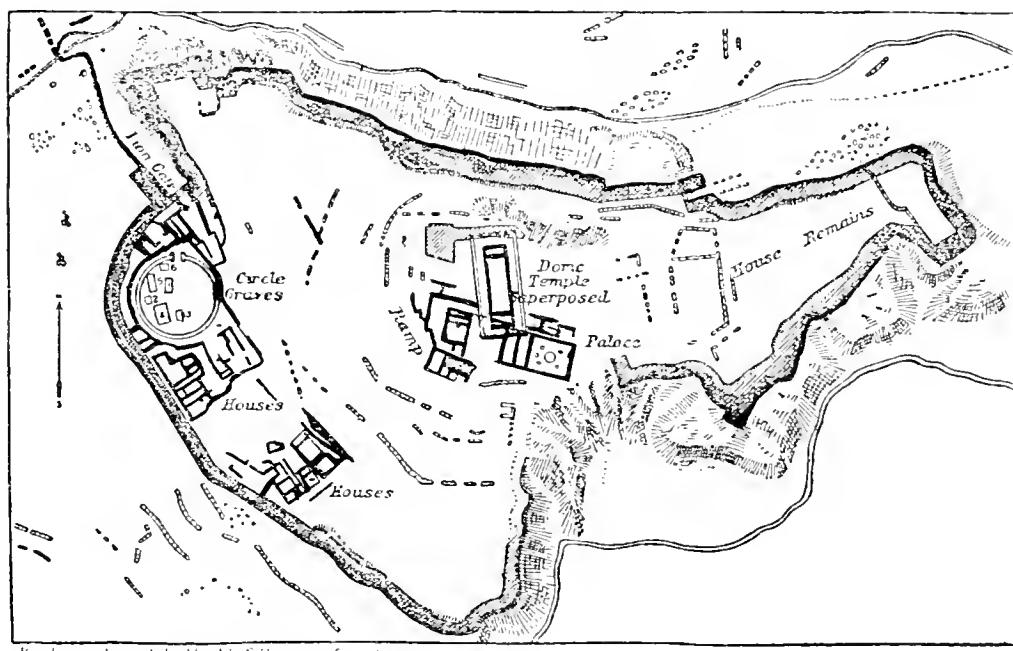

Aqua Marcia, Rome, a waterway which traversed $61\frac{3}{4}$ miles, of which $54\frac{1}{4}$ miles were underground. This aqueduct was reconstructed in 1869-70 under the name of Aequa Pia or Marcia-Pia. (Photo, Dr. T. Ashby. Reproduced from the Encyclopaedia Britannica by courtesy of the publishers.)

ment and discomfort of the passerby. This disgusting habit became such a nuisance that eventually a law was passed prohibiting the practice.

The great aqueducts of Rome are monuments to the genius of their engineers. Like the sewers, some of them are still in use. The story of the first nine aqueducts has been told by Frontinus, a hydraulic engineer and water commissioner of

Rome, who wrote in 97 A.D. He says: "Will any body compare the idle pyramids or those other useless though much renowned works of the Greeks with these aqueducts, with these many indispensable structures?" Prior to the building of the aqueducts the Romans got their water from the sewage-polluted Tiber and from wells, springs and cisterns. The value of pure water was recognized, however, and the citizens were lavish in their expenditures to secure it. They must have realized the truth of the phrase that "public health is purchasable," a fact which many modern communities would do well to recognize for their own benefit.

The first aqueduct was built in 312 B.C. by Appius Clandius, who also is famous for the Appian Way. It was eleven Roman miles (each 4,854 feet) long, most of it being underground. During the next six hundred years twenty aqueducts of varying lengths were built for Rome. The second was in 272 B.C. and M. Aurius Dentatus was the builder; it was 43 miles long. The third was called the Marcia after its constructor, Quintus Marcius Rex, and was 61 miles in length, 7 miles above ground. It furnished the coldest water of all that were built. Next was the Tepula (127 B.C.); then the Julia (35 B.C.). The last three joined near the city and were carried in three stories, in which form they still exist entire. The best known of the aqueducts are the Claudio and the Anio Novus, completed in 50 and 52 A.D., respectively. The former was 46 miles long, the

Plan of the Citadel of Mycenae, the proud city of ancient Greece, founded in the fourteenth century B.C., where excavations have revealed great baths. The desire of the Greeks to promote the health of their population led to the erection of temples situated usually in groves and near springs, which became popular gathering places. (Reproduced from the Encyclopaedia Britannica by courtesy of the publishers.)

latter 58 and together they doubled the water supply of the city. Besides the aqueducts in their capitol the Romans built them in the colonies in Spain, Africa, Greece, and France. Of these, that at Segovia, Spain, is the most perfect remaining. It is of stone without mortar, is 2,400 feet long, and at one point is 100 feet above ground. There are 109 arches. The structure still supplies the city with water.

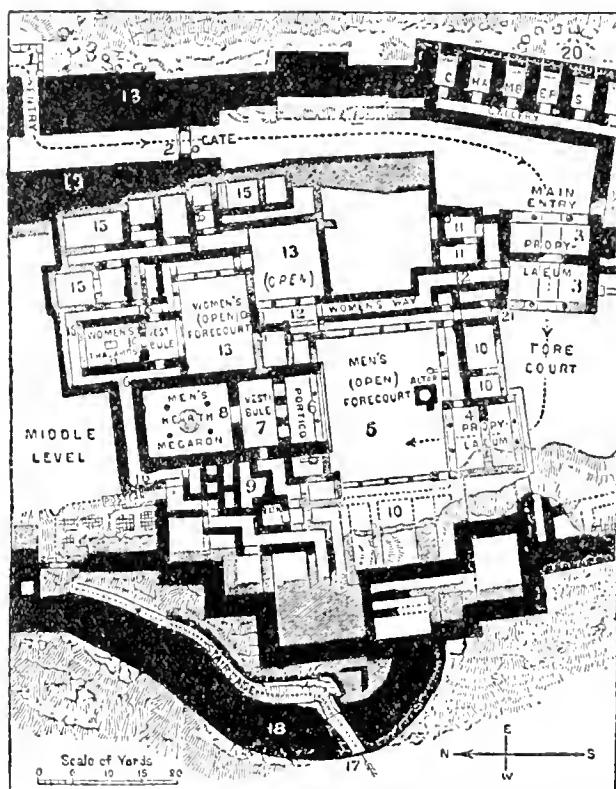

In addition to the aqueducts, the Romans had reservoirs, some of them public and some private. When a number of individuals received a water grant they combined to establish a reservoir for their own use. Each aqueduct was provided with a main reservoir and a number of smaller ones at different places in the section which was supplied by it. One of the principal reservoirs was on the Esquiline Hill. It was 200 feet long and 130 feet wide, and was covered by a vaulted roof, supported on 48 pillars. The authorities must have understood the principle that storage of water where the light is excluded prevents the growth of objectional vegetation and algae.

Bathing was a fine art in Rome and ultimately contributed to the downfall of the empire. The inference should not be drawn from this statement that bathing is detrimental to a nation because, of course, the practice is necessary to hygiene. The Romans made bathing a luxury rather than a procedure to secure cleanliness. Unlike the Greeks, who considered warm water effeminate, the Romans had hot water and anointed the body with oils and perfume. In the later days of the empire men and women bathed together promiscuously in public. The buildings devoted to the pastime were splendid and contained many rooms. The Diocletian baths had accommodations for 3,200 persons at one time.

The ruins of Pompeii also show magnificent baths. The city had a water supply which is estimated to date from the fifth century before Christ. There were a great aqueduct and a complete system of water flushed latrines and sewers. The Roman sewerage systems differed from the Cretan only in the fact that the former used running water from the city supply to flush the toilets, while the latter depended upon rain water. There is a difference of two thousand years between the two, yet they are essentially the same. Furthermore, both resemble the modern.

The Dark Ages followed the downfall of Rome and sanitation suffered a retrogression. Filth and uncleanness reigned supreme and as a consequence plague and pestilence scourged Europe. The Black Death in the fourteenth century A.D. carried off nearly half of the total population of that continent. It seems as if a catastrophe is

necessary to awake peoples to the necessity of preventing such exigencies. The cholera epidemics of the middle of the nineteenth century resulted in a pure water supply and an adequate sewage disposal in London. The many typhoid epidemics traced to polluted water at the end of the nineteenth century served to bring about sanitary reforms in the United States. Within the last few years sanitation has been coming into

Plan of the palace in the Upper Part of Tiryns, the ancient Peloponnesian city, illustrating the arrangement of the bathroom and small retiring rooms, with connecting passageways. The bathroom is 10 feet x 12 feet, with its floor formed of one great slab of stone, sloped so as to drain out at one side through a pipe.

- (1) Main gate in the outer wall; (2) Inner gate, approached between massive walls; (3) Main propylaeum; (4) Inner propylaeum; (5) Court surrounded by a colonnade on three sides, the altar to Zeus Hereus is by the entrance; (6) Portico of the Megaron; (7) Inner porch; (8) Megaron, with roof supported on four columns, and the circular hearth in the middle; (9) Bathroom and small retiring rooms; (10) Chambers round the great court; (11) Guard chambers by the main propylaeum; (12) Passage from the main propylaeum to the second house; (13) Courts of the second house; (14) Megaron; (15) Chambers; (16) Passage to the rock-cut stairs; (17) Small postern door in the semicircular bastion, approached by flight of rock-cut steps; (18) Massive outer wall of city; (19) Inner wall to guard the entrance passage; (20) Part of outer wall, with intermediate passage and rows of chambers. its own in this country and the future should be even more bright.

The history of sanitation repeats itself. We have an honorable heritage and shall give to the world monuments as enduring in the glory of disease prevention as were those of the peoples of the past. To limit sickness to the minimum, to prolong life to the maximum, and reduce the unnecessary death rate of modern times—after all, that will be the real romance of sanitary science.

DISABILITY BY AGE AND OCCUPATION

BY BORIS EMMET, PH.D., MANAGER, LABOR DEPARTMENT, NEW YORK DRESS AND WAIST MANUFACTURERS' ASSOCIATION, NEW YORK CITY; FORMERLY STATISTICAL EXPERT, BUREAU OF LABOR STATISTICS, WASHINGTON, D. C.

THIS article is based upon data contained in an unpublished study made recently by the United States Bureau of Labor Statistics. To arrive at the actual extent of sickness among wage earners, this bureau made an intensive actuarial examination of the disability experience of the Workmen's Sick and Death Benefit Fund of America, a mutual sick and death benefit association, in existence since 1884, and operating on a national scale. The society confines its disability membership almost exclusively to male wage earners, eighteen years of age and over. The disability experience examined represents the average annual sickness for the five-year period ending December 31, 1916, and is, therefore, free from accidental variations, such as, for instance, those caused by the Spanish Influenza epidemic of last year.

First Exact Estimate of Disability

The society pays a sick benefit of \$1.50 per day, or \$9.00 per week, for all disabilities including accidents of various kinds and descriptions. Benefits are paid beginning with the filing of the physician's disability certificate. There is, therefore, no waiting period. The study does not include sickness extending over fifty-two weeks. This defect is, however, negligible for the purpose of determining average disability.

With the exception of the estimates furnished by the recent health surveys¹ of the Metropolitan Life Insurance Company, and some fragmentary data based upon the experi-

This study is an actual measurement of the disability experience of 40,000 wage earners in forty-two occupations. Credit is acknowledged to Royal Meeker, United States Commissioner of Labor Statistics, for permission to compile and publish the data upon which this article is based. Accepted estimates of average disability which have been deduced from health surveys or fragmentary data relating to selected groups, are lowered in this study. Careful analyses have been undertaken to determine the relative disability by occupation with a view to placing the responsibility for sickness and obtaining an equitable distribution of the burden.

The society confines its disability membership almost exclusively to male wage earners, eighteen years of age and over. The disability experience examined represents the average annual sickness for the five-year period ending December 31, 1916, and is, therefore, free from accidental variations, such as, for instance, those caused by the Spanish Influenza epidemic of last year.

ence of certain establishment funds, no exact measurement has ever been made of the annual average number of disability days per wage earner by age and occupation in the United States. The study of the Federal Bureau of Labor Statistics upon which this article is based furnishes, therefore, the first official and exact measurement of such disability among wage earners.

The common prevailing estimate of the annual average number of disability days per person—an estimate usually acquiesced in by the proponents and opponents of health insurance—has been nine days. This figure is based upon fragmentary data as well as on the general assumption that the extent of sickness in the United States is similar to the sickness experience of European countries which have state health insurance schemes in operation, notably Germany. In this connection it is to be noted that the data from the establishment fund studies is only for days compensated, and not for total days of sickness.

The results obtained in connection with the study, the results of which are presented herewith show an average annual number of disability days

of 6.6—considerably below the prevailing mentioned estimates. The figure is to be considered as reliable because (a) it is an actual measurement and not an estimate; (b) it is based upon the disability experience of more than forty thousand wage earning persons engaged in over forty-two separate and distinct occupations. The bureau figure, 6.6, represents all disability

CHART I
AVERAGE ANNUAL NUMBER OF DISABILITY DAYS PER MEMBER (ALL OCCUPATIONS) IN CERTAIN AGE GROUPS.

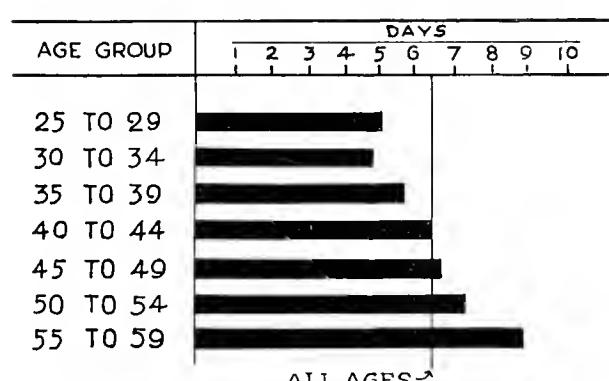

Chart showing ratio of sickness in the various age groups.

and approximates closely the estimates made recently in connection with the sickness surveys of the Metropolitan Life Insurance Company¹—6.8. Seven days, or thereabout may, therefore, be said to be the annual average number of disability days per wage earner.

Age and Disability

Table I gives the average annual number of disability days per member of certain indicated age groups. As may be seen from the column entitled "average number of disability days per member," the extent of sickness up to the age of 44 is slightly below the average. Beginning with the age group of 45 to 49, the extent of sickness is progressively on the increase. The disability figures show an unmistakable tendency for sickness to increase with age. This tendency is illustrated in Chart I, accompanying Table I.

The figures of the table and the chart are so clear in their trend that they need not be commented upon at length. The influence of age upon disability is shown in absolute numbers. Table II and Chart II accompanying it represent an attempt to show the influence of the age factor upon disability.

The standard of comparison in Table II is the average number of disability days for all age groups, that is, for the society as a whole. In the calculations made, the disability of the entire organization, per member, or per disabled person, is equivalent to 100. The disability of each particular age group is then reduced to a percentage of this standard unit and an index number thus arrived at.

¹ Sickness Survey of Principal Cities in Pennsylvania and West Virginia, Sixth Community Sickness Survey, by Lee K. Franklin and Louis L. Dublin, Metropolitan Life Insurance Co., N. Y., 1931, pp. 76-78.

TABLE I
AVERAGE ANNUAL NUMBER OF DISABILITY DAYS PER MEMBER AND DISABLED PERSON OF EACH CLASSIFIED FIVE-YEAR AGE GROUP

Age Group	Total No. of disability days	Total No. of members affected	Number of disabled persons	Average No. of disability days per member	Average No. of disability days per disabled person
Under 20	2,108	466	127	5.2	16.6
20 to 24.....	34,296	7,168	1,778	4.8	19.3
25 to 29.....	76,619	15,267	3,574	5.0	21.4
30 to 34.....	106,162	21,886	4,862	4.9	21.8
35 to 39.....	155,209	27,496	6,197	5.6	25.0
40 to 44.....	196,206	30,736	7,104	6.1	27.6
45 to 49.....	206,860	31,579	7,150	6.6	28.9
50 to 54.....	189,850	25,484	6,044	7.4	31.4
55 to 59.....	146,777	16,229	4,168	9.0	35.2
60 to 64.....	80,459	6,639	1,859	12.0	43.3
65 to 69.....	25,361	1,843	557	13.3	45.5
70 and over..	3,417	225	65	15.2	52.6
Total	1,223,324	185,018	43,485	6.6	28.1

It will be noted that the number of disability days increases progressively toward the higher age groups.

CHART II

PER CENT DEVIATIONS OF DISABILITY DAYS OF INDICATED AGE GROUPS,
FROM THE AVERAGE NUMBER OF DISABILITY DAYS FOR ALL AGE GROUPS.
(AVERAGE DAYS OF DISABILITY FOR ALL AGE GROUPS = 100)

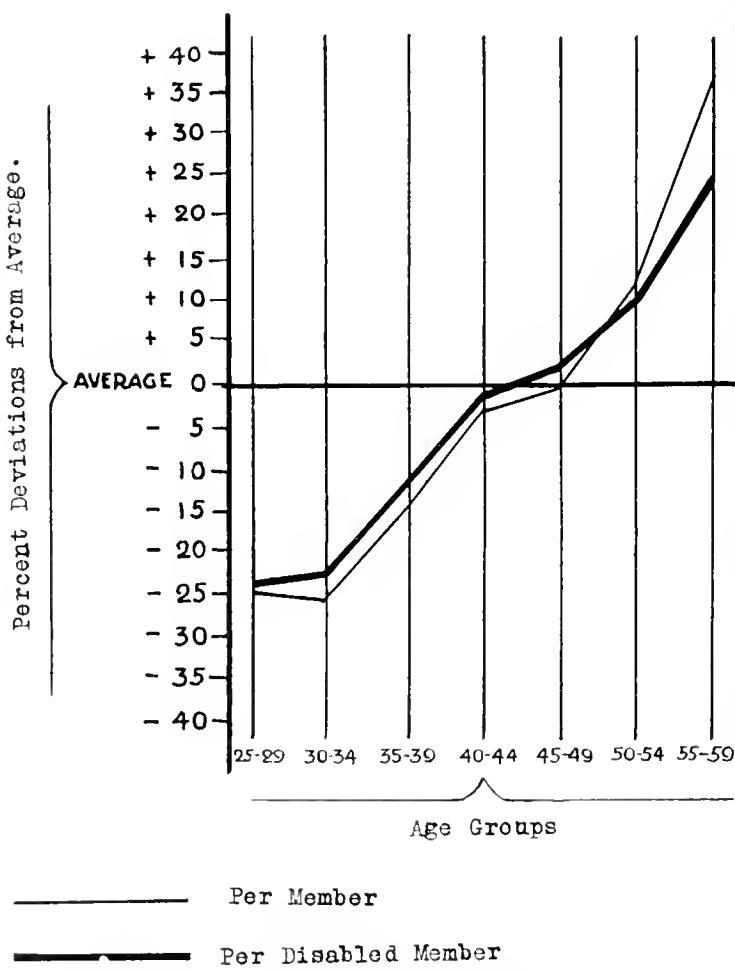

Chart setting forth the influence of the age factor upon disability.

With reference to average disability per member, each age group up to and including 45 to 49, shows a negative deviation from the average, that is, an extent of sickness below the average. The least extent of sickness, 27.3 per cent less than the average, is found in group 20 to 24. The extent of disability increases with age. Age group 45 to 49 shows an extent of sickness equivalent approximately to the average. This is to be expected in view of the fact that the average of the membership is about 43 years. The extent of disability in the age group 55 to 59 is about one-third greater than the average, and in age group 60 to 64 more than four-fifths. Age groups 65 to 69 and 70 and over show disability extents more than twice greater than at the average age.

The figures given in the last column of the table indicate that the duration of disability does not increase with increase of age as rapidly as the average number of disability days per member. The average is approximated in group 45 to 49. In the 55 to 59 age group the number of disability days per disabled person is one-fourth greater than the average. Age

groups 60 to 64, 65 to 69, and 70 and over, show durations of disability 54.1 per cent, 61.9 per cent, 87.2 per cent, respectively, greater than the average.

An attempt has been made in Table III to establish the relative disability responsibility of certain age groups.

CHART III

CORRECTED ANNUAL DISABILITY DAYS FOR EACH OCCUPATION (AGE GROUPS, 25 - 59).

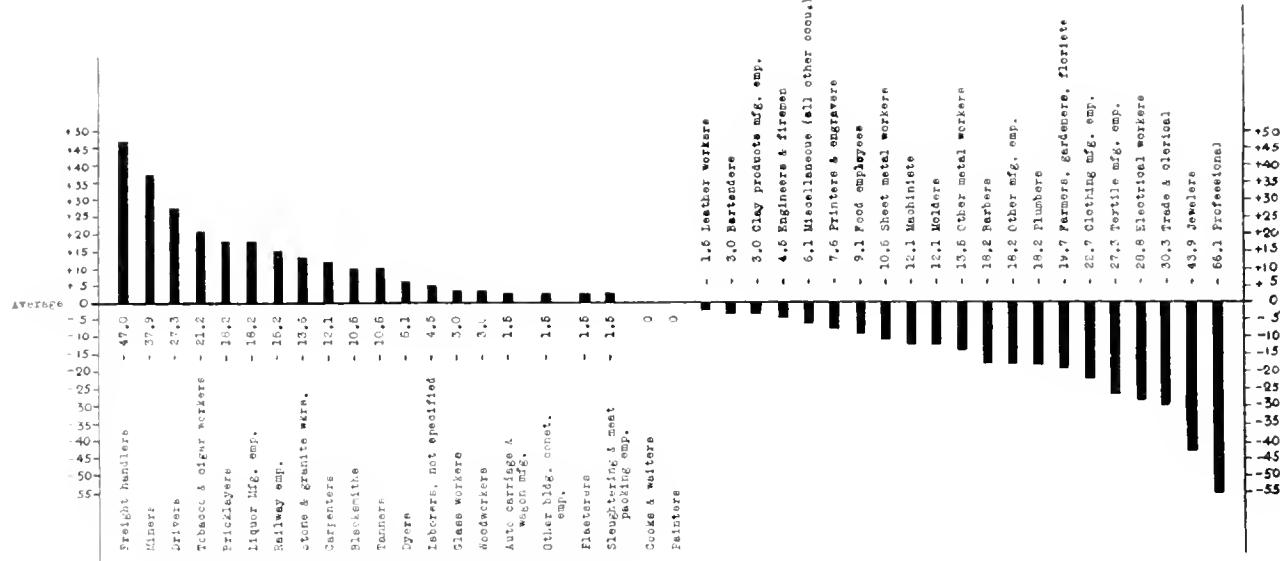

Occupation	Average Annual Number Disability Days Per Member									
	1	2	3	4	5	6	7	8	9	10

43. All occupations	:	:	:	:	:	:	:	:	:	6.4

The above chart sets out more clearly the variations of disability by industrial groups worked out in Table IV.

The relative disability responsibility is found by comparing the strength, the per cent of total, of each group in the organization with the proportion of disability days for which it is responsible. Without the presence of disability variations due to age, the per cent strength of each group should be equivalent to the per cent of disability days caused by it. For this reason, it may be said, that the extent of discrepancy between the two figures indicates more or less correctly the relative disability responsibility of the unit. Age group "under 20," while 0.22 per cent strong, was responsible only for 0.17 per cent of the disability days. On the other hand, age group "70 and over," only 0.12 per cent strong, was responsible for an extent of sickness more than twice greater than its propor-

CHART IV

PERCENT DEVIATION OF AVERAGE ANNUAL DISABILITY DAYS PER MEMBER OF EACH INDICATED OCCUPATION FROM THE AVERAGE ANNUAL DISABILITY DAYS PER MEMBER FOR ALL OCCUPATIONS. (AVERAGE DAYS OF DISABILITY PER MEMBER OF ALL OCCUPATIONS = 100)

The deviations in the number of disability days from the average for all occupations is an index as to the hazards of the various occupations. It is highest for freight handlers, and lowest among professional employees.

tion, or 0.28 per cent. Age group 30 to 34 appears to have been the least costly to the society; it was 11.83 per cent strong, but responsible only for 8.68 per cent of the disability days.

Occupation and Disability

The figures presented in the following section indicate that, with a few exceptions, occupational disability consists largely of industrial accidents.

TABLE II

PER CENT DEVIATIONS OF DISABILITY DAYS OF EACH INDICATED AGE GROUP FROM THE AVERAGE NUMBER OF DISABILITY DAYS FOR ALL AGE GROUPS

(Average days of disability for all age groups = 100)

Age Group	Per Member		Per Disabled Person	
	Average number of disability days	Per cent of deviation from average of all indicated age groups	Average number of disability days	Per cent of deviation from average of all indicated age groups
Under 20	5.2	+ 21.2	16.6	+ 10.9
20 to 24	4.8	+ 27.3	19.0	+ 31.3
25 to 29	5.0	+ 24.2	21.4	+ 23.8
30 to 34	4.9	+ 25.2	21.7	+ 22.4
35 to 39	5.6	+ 15.1	25.0	+ 11.0
40 to 44	6.1	+ 3.9	27.6	+ 1.8
45 to 49	6.6	None	28.9	+ 2.9
50 to 54	7.4	+ 12.1	31.4	+ 11.7
55 to 59	9.0	+ 35.4	35.2	+ 25.3
60 to 64	12.0	+ 81.8	43.3	+ 54.1
65 to 69	13.8	+ 10.1	45.5	+ 61.9
70 and over	15.2	+ 130.3	52.6	+ 87.2
Average, all age groups	6.6	None	28.1	None

What may be considered as the normal average of sickness and disability is found in age group 45 to 49, the average age for the whole membership being 43 years.

One of the exceptions, more apparent than real, seems to be tobacco and cigar workers who, because of their work, are known to be frequently affected with tuberculosis, which is in these workers an industrial disease. The group of workers shows an average disability of 8.01 days per year per worker as against 6.61 days per year, which is the average for all occupations.

Table IV shows the average annual number of disability days per member. Both crude (uncorrected for age distribution) and corrected (for age distribution) figures are presented.

TABLE III

RELATIVE DISABILITY RESPONSIBILITY OF EACH CLASSIFIED FIVE-YEAR AGE GROUP

Age Group	Total number of members	Per cent of total membership	Aggregate of disability days of age group	Per cent of disability of entire membership
Under 20	406	0.22	2,108	0.17
20 to 24	7,168	3.87	34,296	2.80
25 to 29	15,267	8.25	76,619	6.26
30 to 34	21,886	11.83	106,162	8.65
35 to 39	27,196	14.86	155,209	12.65
40 to 44	30,746	16.62	196,205	16.04
45 to 49	31,579	17.77	206,860	16.91
50 to 54	25,484	13.77	189,550	15.52
55 to 59	16,229	8.77	146,777	12.00
60 to 64	6,689	3.62	80,459	6.58
65 to 69	1,843	1.00	25,363	2.07
70 and over	225	0.12	3,417	0.28
Total	185,018	100.00	1,223,324	100.00

The disability responsibility by age groups is developed in this table. The figures show that the age group 30 to 34 accounts for the lowest percentage of disability.

Chart III illustrates more clearly the facts shown in Table IV.

In Table IV and Chart III occupational disability is shown in order of magnitude. Miners show the highest annual average number of disability days, 9.7, as against 6.4, the average for all occupations. Freight handlers are the next group in point of disability, with an average number of disability days per member of 9.6 days per year. Drivers, with an average of 8.6 days of disability per member come next. Jewelers and professional workers show the least extent of sickness 3.6 and 2.6 days, respectively, per year. The high disability extents of the first three groups is accounted for no doubt by the

hazardous character of the work which makes for frequent industrial accidents.

Table V shows still more clearly the extent of occupational disability.

High Disability in Some Groups

The table shows the per cent deviations of the average annual number of disability days of each occupation from the average annual number of disability for all occupations. The extent of deviation from the average indicates the so-called healthfulness of the group. A negative variation from the average indicates better health or less sickness, while a positive deviation indicates more disability; that is, less health.

TABLE IV

CRUDE AND CORRECTED ANNUAL NUMBER OF DISABILITY DAYS PER MEMBER IN CERTAIN AGE GROUPS (25-59)

Occupation	Annual average number of disability days per member	
	Crude (irrespective of specific age distribution within occupation)	Corrected for age factor according to method
1. Auto, carriage and wagon mfrg. employees	5.99	5.86
2. Barbers	5.57	5.88
3. Bartenders	6.17	5.98
4. Blacksmiths	7.09	6.89
5. Bricklayers	7.35	7.13
6. Carpenters	6.91	6.69
7. Clay products manufacturing employees	6.44	6.55
8. Clothing manufacturing employees	4.66	4.44
9. Cooks and waiters	6.38	6.15
10. Drivers	8.46	8.59
11. Dyers	7.06	6.44
12. Electrical workers	4.64	4.79
13. Engineers and firemen	6.05	6.01
14. Farmers, gardeners, florists	5.22	5.28
15. Food employees	5.94	6.22
16. Freight-handlers	9.61	9.56
17. Glass workers	6.81	7.09
18. Jewelers	3.55	3.59
19. Laborers, not specified	6.88	6.92
20. Leather workers	5.98	6.75
21. Liquor manufacturing employees	7.76	7.94
22. Machinists	5.82	6.11
23. Miners	9.16	9.67
24. Miscellaneous (all other occupations)	5.69	5.72
25. Molders	5.71	6.84
26. Other building construction employees	6.62	6.57
27. Other manufacturing employees	5.12	6.14
28. Other metal workers	6.30	6.36
29. Painters	6.42	6.35
30. Plasterers	5.51	5.62
31. Plumbers	6.05	5.66
32. Printers and engravers	6.02	6.10
33. Professional	2.43	2.65
34. Railway employees	7.80	8.37
35. Sheet metal workers	6.72	6.66
36. Slaughtering and meat packing employees	6.45	6.86
37. Stone and granite workers	7.69	7.53
38. Tanners	6.61	5.80
39. Textile manufacturing employees	4.59	4.49
40. Tobacco and cigar workers	7.03	6.80
41. Trade and clerical	4.54	4.70
42. Woodworkers	6.48	6.14

A study is made in this tabulation of the disability by industrial groups in an effort to determine the influence of occupational diseases upon the normal averages.

TABLE V

PER CENT DEVIATIONS OF AVERAGE ANNUAL DISABILITY DAYS OF EACH INDICATED OCCUPATION FROM THE AVERAGE ANNUAL DISABILITY DAYS OF ALL OCCUPATIONS

(Average Days of Disability for all Occupations = 100)

Occupation	Average number of disability days	Per Member		Per Disabled Person	
		Per cent deviation from average of all occupations	Average number of disability days	Per cent deviation from average of all occupations	Per cent deviation from average of all occupations
1. Auto, carriage and wagon mfg. employees	6.7	+ 1.5	27.5	- 2.1	
2. Barbers	5.5	- 18.2	29.7	+ 5.7

33. Professional	2.9	- 56.1	24.0	- 14.6	
34. Railway employees	7.6	+ 15.2	29.7	+ 5.7	
35. Sheet metal workers	5.9	- 10.6	26.9	- 4.3	
36. Slaughtering and meat packing employees	6.7	+ 1.5	28.4	+ 1.1	
37. Stone and granite workers	7.5	+ 13.6	32.2	+ 14.6	
38. Tanners	7.3	+ 10.6	26.8	+ 2.5	
39. Textile manufacturing employees	4.9	- 27.3	26.3	- 6.4	
40. Tobacco and cigar workers	8.0	+ 21.2	31.0	+ 10.3	
41. Trade and clerical	4.6	- 30.3	27.2	- 3.2	
42. Woodworkers	6.8	+ 3.0	31.1	+ 10.7	
Average, all occupations		6.6	None	28.1	None

The comparison of disability variations from the average for the several occupations would seem to be a fair indication of the influence of occupational disease and accidents.

The figures show the following facts regarding the extent of disability shown by the average annual number of disability days per member. The largest average number of disability days, 9.7 per year, or 47 per cent greater than the average, was found among freight handlers. This group of members had an average of 40, or about three years less than the average for the society. The high disability rate is, therefore, to be accounted for by sickness due to accidents and physical overstrain which are known to be very frequent because of the character of the occupation. The same point may be made regarding the miners, who show the next highest average number of disability days, 9.1 per member, or 37.9 per cent greater than the average for the entire society. Drivers, with an average age of 42 or about one year below that of the society, show an average

of disability days per member of 8.4 days, or 27.3 per cent greater than the average. Professional employees, jewelers, trade, and clerical employees appear to be, in the order named, the least sickly workers. Respectively, these occupations show the following extents of sickness below the average: Professional, 56.1 per cent; jewelers, 43.9 per cent; trade and clerical, 30.3 per cent. These figures are graphically illustrated in Chart IV. Table VI shows the relative disability responsibility of each occupation.

The relative disability responsibility of each occupation is shown in Table VI by comparing the strength of the occupation, per cent of total membership, with the relative number of disability days charged up to it. Without the presence of disability variations due to the occupational factor, and incidental to it specific age distribution, the per cent strength of each group should be equal to the proportion of disability days charged against it. The extent of discrepancy between the two figures constitutes, therefore, a correct measurement of the disability responsibility of the occupation. Such an illustration is furnished by the first occupation shown in the table, carriage and wagon manufacturing employees. This occupation was 0.4 per cent strong, and was responsible for 0.4 per cent of the total of disability days. It thus supported itself. The barbers, though 0.67 per cent strong, were responsible for an extent of sickness less than their respective strength—only 0.55 per cent of the total disability days. This means that some proportion of the income derived from the barbers was used to support an occupation which had a disability extent greater, relatively, than its strength. The miners present just such a group. While constituting only 3.82 per cent of the membership, they were responsible for 5.25 per cent of the total of disability days.

Italy Still Fighting Tuberculosis

Italy is strenuously continuing the fight against tuberculosis since the declaration of peace, having taken over the work started by the American Red Cross during the conflict. The armies continue to contribute their quota of patients. The Central Sanitary Commission for Anti-Tuberculosis Activity was started late in 1917, and formed the basis of the present organization. A social health bureau also has been formed in Rome, under the Red Cross, from which workers are sent out, functioning through local chapters. Twelve hospitals afford accommodations for 2,500 patients. They are favorably located for climate and cover three types of cases, the curable, those more advanced, and those in the last stages. A hospital for children recently has been opened in Rome, also several nursery-schools for those of tuberculous tendency. The American Red Cross operated twenty-two military hospitals with 14,326 beds occupied when fighting ceased.

TABLE VI

RELATIVE DISABILITY RESPONSIBILITY OF EACH OCCUPATION (ALL AGE GROUPS)

Occupation.	Total number of members	Per cent of total membership	Aggregate of disability days of occupation	Per cent of disability days of entire membership
1. Auto., carriage and wagon mfg. employees...	735	0.40	4,954	0.40
2. Barbers	1,242	0.67	6,770	0.55
3. Bartenders	2,290	1.24	14,772	1.21
4. Blacksmiths	2,053	1.11	15,022	1.23
5. Blacklayers	2,241	1.21	17,566	1.44
6. Carpenters	11,662	6.31	86,632	7.08
7. Clay products mfg. employees	652	0.35	4,161	0.34
8. Clothing manufacturing employees	4,847	2.62	24,690	2.02
9. Cooks and waiters	2,335	1.26	15,501	1.27
10. Drivers	6,890	3.72	57,731	4.12
11. Divers	748	0.40	5,263	0.43
12. Electrical workers	988	0.53	4,699	0.38
13. Engineers and firemen	3,387	1.83	21,460	1.75
14. Farmers, gardeners and florists	1,203	0.65	6,351	0.52
15. Food employees	7,484	4.05	41,786	3.66
16. Freight handlers	721	0.39	7,020	0.57
17. Glass workers	955	0.52	6,482	0.53
18. Jewelers	1,165	0.63	4,325	0.35
19. Laborers, not specified	17,685	9.56	122,813	10.04
20. Leather workers	4,311	2.33	28,085	2.30
21. Liquor manufacturing employees	14,324	7.71	111,132	9.09
22. Machinists	16,025	8.66	93,265	7.62
23. Miners	7,067	3.82	64,211	5.25
24. Miscellaneous (all other occupations)	9,258	5.00	57,708	4.72
25. Molders	2,841	1.54	16,582	1.36
26. Other building construction employees	588	0.32	3,957	0.32
27. Other manufacturing employees	4,164	2.25	22,661	1.85
28. Other metal workers	6,907	3.73	39,266	3.21
29. Painters	4,389	2.37	28,939	2.37
30. Plasterers	558	0.30	3,749	0.31
31. Plumbers	1,448	0.78	7,819	0.64
32. Printers and engravers	3,391	1.83	20,582	1.68
33. Professional	1,189	0.64	3,510	0.29
34. Railway employees	691	0.37	5,249	0.43
35. Sheet metal workers	2,343	1.27	13,813	1.13
36. Slaughtering and meat packing employees	5,716	3.09	38,309	3.13
37. Stone and granite workers	1,169	0.63	8,785	0.72
38. Tanners	1,466	0.79	10,655	0.87
39. Textile manufacturing employees	7,287	3.91	35,315	2.89
40. Tobacco and cigar workers	8,897	4.81	71,233	5.82
41. Trade and clerical	5,587	3.02	25,951	2.12
42. Woodworkers	6,092	3.29	41,197	3.39
Total	185,018	100.00	1,223,321	100.00

A correct measurement of the disability responsibility of each occupation is made by comparing the strength of the occupation with the disability charged up to it. It demonstrates that some industries carry an appreciable portion of the disabilities of the other groups.

JEWISH HEALTH WORK

BY H. J. MOSS, M.D., SUPERINTENDENT, HEBREW HOSPITAL, BALTIMORE, MD.; CHAIRMAN, HEALTH SECTION, NATIONAL CONFERENCE OF JEWISH CHARITIES*

THE new day is at hand when the welfare of the masses of the people is becoming more the concern of the whole people, and the Government of our country is already devoting its best thought and attention to the questions of health, health conservation, and disease prevention, to the end that we may have a strong, vigorous, robust, and healthy people of whom these United States may be proud, and thus retain the magnificent place our soldiers won for us on the battlefield.

In a report to Congress on the state of the public health with recommendations indorsed by President Wilson, wide extension of the United States Public Health Service is urged, an extension in which the Federal Government will assume close supervision of state and municipal health activities. The report, coming through the Department of the Treasury, to which the Public Health Service is attached, called attention to the deplorable situation revealed by the Army draft. The completed Army draft records show that more than 34 per cent of all the draft registrants were rejected by examining boards on account of physical defects and diseases.

Disease Due to Neglect

To meet this terrific drain on the man resources of the country, a war-time public health program was formulated. Now, in the interests of the nation as well as of individuals, with slight modifications, it is proposed to make this war-time program a permanent peace-time governmental policy.

A part of the program says:

"Recruiting statistics have revealed the terrible conditions as regards the physical health of the nation. This is not due to poverty but neglect. The health of the people must be the special concern of the state. To help meet the serious

MAKING COMMUNITIES SAFE FOR THE HEALTH OF CITIZENS

The Jewish Health Program contemplates a survey and study of the diseases common to the peoples of Jewish communities.

By learning the mortality and morbidity rates in Jewish communities, efforts may be directed toward the reduction and elimination of the more prevalent diseases and their causative factors.

The aims and methods of the Jewish Health Bureau of Baltimore are here outlined; in general these aims embrace those which it is proposed shall be adopted as a national Jewish Health Program.

tigations, 20; health education, 10. Calling attention to a situation set forth as nothing short of appalling, the report, after stating that more than 34 per cent had to be rejected, says:

Rural and Industrial Hygiene

"For patent economic reasons the need of conserving life and health is all the more urgent in order to permit recovery from war losses in the shortest possible time, and to render even reasonably safe the development of new agricultural and industrial resources. It is essential at this time that the Federal Government assume leadership in stimulating states, counties, and municipalities in improving their sanitary conditions to the best interests of communities. In order that thousands of lives may be saved, it is proposed for the Federal Government to prosecute in part the following program, including industrial and rural hygiene. The former would include:

"1. Continuing and extending health surveys in industry with a view to determining precisely the nature of the health hazards and the measures needed to correct them.

"2. Securing adequate reports of the prevalence of disease among employees and the sanitary conditions in industrial establishments and communities.

"3. National development of adequate systems of medical and surgical supervision of employees in places of employment.

"4. The establishment of the Public Health Service, in cooperation with the De-

*Read before the National Conference of Jewish Charities, Atlantic City, N. J., May, 1919.

partment of Labor, of minimum standards of industrial hygiene and the prevention of diseases."

Health Needs Are Universal

Not only has the attention of our own country been concentrated on health, but the whole world is awakened to the realization that every effort must now be made to ameliorate those conditions responsible for ill health and disease. In other words, the world must be made safe to live in, not only from a military point but from the health point of view. This is manifest from the announcement made by the American Red Cross Society early in May that fifteen of America's leading health specialists, acting with distinguished physicians and scientists of England, France, Japan, and Italy, at the Interallied Red Cross Conference at Cannes, France, had affixed their names to a resolution telling of the purpose "to spread the light of science and the warmth of human sympathy into every corner of the world."

The text of the resolution adopted is as follows:

"We are assembled at the invitation of the Committee of the Red Cross Societies to assist in the task for which the Committee was constituted, namely, to formulate and propose to the Red Cross Societies of the world an extended program of Red Cross activities in the interest of humanity. In addressing ourselves to this task, we desire to express our belief that while every measure should be taken to repair the ravages of war and prevent all wars, it is no less important that the world should address itself to the prevention and amelioration of those ever present tragedies of unnecessary sickness and death which occur in the homes of all peoples.

"This world-wide prevalence of disease and suffering is in considerable measure due to widespread ignorance and lack of application of well established facts and methods capable either of largely restricting disease or of preventing it altogether. It is clear that it is most important to the future progress and security of civilization that intelligent steps be taken to instruct the peoples of the world in the observance of those principles and practices which will contribute to their health and welfare.

Educated World-Opinion

"In the accomplishment of these great aims it is of supreme consequence that the results of the studies and researches of science should be made available to the whole world: that high standards of practice and proficiency in the prevention of disease and preservation of health should be promoted and supported by an intelligent and

educated public opinion, and that effective measures should be taken in every country to secure the utmost cooperation between the people at large, and all well directed agencies engaged in the promotion of health.

"We have carefully considered the general purposes of the Committee of Red Cross Societies whereby it is proposed to utilize a central organization which shall stimulate and coordinate the voluntary efforts of the people of the world through their respective Red Cross societies which shall assist in promoting the development of sound measures for public health and sanitation, the welfare of children and mothers, the education and training of nurses, the control of tuberculosis, venereal diseases, malaria, and other infectious and preventable diseases; and which shall endeavor to spread the light of human science and the warmth of human sympathy in every corner of the world, and shall invoke in behalf of humanity not alone the results of science but the daily efforts of men and women of every country, every religion, and every race.

"We believe that the plans now being developed should at the earliest practicable moment be put into effect and placed at the disposal of the world. In no way can this be done so effectively as through the Red Cross, hitherto largely representing a movement for amelioration of conditions due to war, but now surrounded by a new sentiment, and the wide support and confidence of the peoples of the world, and equipping it to promote effective measures for human betterment under conditions of peace. We are confident that this movement, assured as it is at the outset of the moral support of civilization, has in it great possibilities of adding immeasurably to the happiness and welfare of the world."

Jews Organize for Health

We, as Jews who have always been a leading factor in every progressive movement, must now also divert our attentions to the question of health as it relates to our co-religionists, irrespective of the plans of the governments, states, or municipalities. We have in the past recognized the need of Jewish hospitals, Jewish tuberculosis sanatoria, Jewish convalescent homes, Jewish homes for incurables, etc. These institutions have always been recognized as the most efficient in their respective communities. Why not now Jewish health organizations? Why not concentrate upon the causes of ill health of our people? Are we not better qualified to understand the needs of our people than is the government?

A recent investigation into the causes of poverty in 8,500 cases undertaken on a scale not

hitherto attempted in any city, by the Bureau of State and Municipal Research of Baltimore City, revealed the astounding fact that 50 per cent of the cases of poverty were directly traceable to ill health. Does this not suggest that our whole treatment of poverty has been erroneous? Have we not been treating symptoms rather than the disease itself? Is not the time mature for radical changes in the administration of our charitable and philanthropic agencies?

Sends Questionnaire to 110 Cities

A questionnaire mailed by the writer to Jewish communities of 110 cities, disclosed the following interesting facts which emphasize the inadequacy and unpreparedness of most of our Jewish communities throughout the country for meeting their needs on the matter of health.

There are but fourteen Jewish hospitals, five tuberculosis sanatoria, four homes for incurables, and four convalescent homes. Not a single community is in a position to know how many Jewish incurables are in their midst. In but a few of the largest cities medical social service is practiced. Not a single community knows the mortality or morbidity rates of the Jewish population. Not a single community knows which are the prevailing diseases, or those causing death among our people. Not a single community is endeavoring to take steps for the eradication and prevention of tuberculosis, the work being done by the local tuberculosis organizations, which at best is none too good. In only seven cities are attempts made in the way of health education. Four cities have societies of mental hygiene and prophylaxis. Twelve cities have organizations for prevention of infant mortality, five have undertaken prenatal work, and seven have societies for prevention of venereal diseases.

Realizing our shortcomings in Baltimore, and feeling the need of a greater sphere of health work not undertaken even by the municipal health organizations, we have recently called into being the Jewish Health Bureau, whose purposes are to study, investigate, and inquire into the conditions affecting the health of the Jews in our city, and to take action from time to time as may tend to ameliorate these conditions. The Bureau consists of two representatives from every Jewish Institution engaged in health work of some form.

Jewish Health Aims in Baltimore

For the achievement of the objects and purposes of the Bureau, the following program is contemplated:

1. (a) The initiation of a survey and a study of the diseases common to our people.

(b) The determination of mortality rates and statistics of the various diseases; after such determination, the taking of such steps as may be necessary to bring about, if possible, a reduction or entire elimination of those causes by instituting proper methods of prevention.

2. (a) The study of the prevalence of tuberculosis in our community. (b) The ascertaining of the number of cases under treatment in sanatoriums, hospitals, and homes. (c) A systematic examination of all members of families wherein tuberculosis has developed; a determination of the probable causes of the disease in these families and, if possible, to remove such causes. (d)) A systematic following up of all arrested or so-called cured cases.

3. (a) The study of the existing chronic incurables among our people. (b) The ascertaining of the numbers confined in hospitals and homes. (c) The determination which of the disabled are in a physical condition to support themselves wholly, partly, or not at all.

4. The provision of ways and means to care for convalescent patients or the over-worked.

5. The inauguration of a health educational campaign with systematic lectures on general and personal hygiene, and prevention of disease.

An Intensive Health Campaign

The Bureau took up the matter of health education as the first important part of the program, feeling that the people were never in a more receptive state of mind on the question of health than they are today. A special committee with the writer as chairman was appointed to draft a program for a health week during which were to be emphasized the most vital subjects relating to public health. A publicity committee was also appointed to stir up our community and urge everyone to attend the various sessions. All of the Baltimore newspapers cooperated in the most admirable manner. The Surgeon General of the United States Public Health Service, the state and city health departments, the Maryland Society for the Study and Prevention of Tuberculosis, the Johns Hopkins School of Hygiene, the Babies' Milk Fund Association, the Visiting Nurses' Association, all cooperated to make the campaign a success.

The campaign opened on Sunday evening, April 6, at the Victoria Theater. The hall was filled to its utmost capacity and hundreds were turned

away. Addresses were made by a representative of the Surgeon General of the United States Public Health Service, the health commissioner of Baltimore, and other prominent physicians and sanitarians. Thereafter, all meetings were held at the Jewish Educational Alliance, the headquarters of the campaign.

The features of the work were: (1) free dental examination every day from 1 to 5 p. m.; (2) nightly food exhibits and demonstrations arranged by Professor McCullum of the Johns Hopkins School of Hygiene; (3) nightly tuberculosis exhibits; (4) nightly home nursing classes; (5) daily demonstrations on care of babies by the Babies' Milk Fund Association; and (6) the specially interesting presentation of motion pictures carefully selected and having a direct bearing on the subject discussed, which did a great deal to emphasize the points we wished to convey.

Monday evening was devoted to personal hygiene, viz.: the value of bathing; clean clothing; the value of sleep; rest, recreation, and vacation. Tuesday was given over entirely to foods and nutrition, with proper exhibits and demonstrations by dietitians and food experts.

Hygiene of the mouth, ear, nose, and throat, were discussed on Wednesday. Thursday was devoted to the care of babies and children. Also there were two sections, one for men and one for women, on sex hygiene. Saturday was taken up with the discussion of chronic diseases, tuberculosis included, and their prevention, and also con-

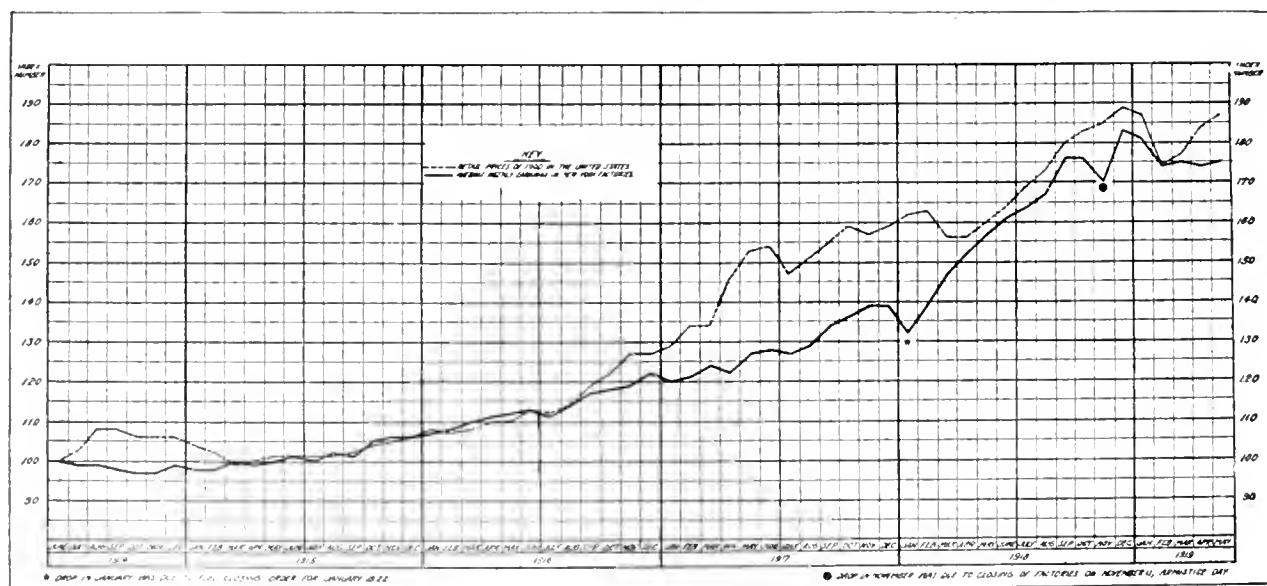

tagious diseases and their prevention. Sunday, the last day of the campaign, emphasized general sanitation and hygiene, such as fighting flies and vermin, the danger of overcrowding, the importance of ventilation, and general cleanliness.

The success of the campaign stimulated our Health Bureau to greater activities. We hope to continue our program of health education. It is our intention to have at least one big meeting a month in a very large hall or theater at which time we will take up some important health subject.

We also expect to begin the other sections of our working program and hope to report similar progress in time. We believe we are working along proper lines, realizing, as everyone should, that to prevent disease is to prevent poverty and misery. We trust that other communities will profit by our experience and concentrate their efforts in the same direction.

As chairman of the Committee on Health of the National Conference of Jewish Charities, it became my duty to outline a health program dealing with all important questions relating to health. Inasmuch as this is the first attempt of the Conference to devote an entire day for the purpose, the Association is to be congratulated on having been able to obtain participants who are experts in their respective lines, able to present the different phases of the subject in an authoritative manner which cannot fail to be of benefit to each individual social worker and to promote a general program of Jewish health work.

COMPARISON OF COURSE OF AVERAGE WEEKLY EARNINGS IN NEW YORK STATE FACTORIES, WITH COURSE OF RETAIL FOOD PRICES IN THE UNITED STATES. COMPILED BY THE NEW YORK STATE INDUSTRIAL COMMISSION AND PUBLISHED IN THE LABOR MARKET BULLETIN.

After a sharp divergence in 1914 the cost of living and earnings increased together until the late summer of 1916, when the increase in the cost of living diverged upward and was not approached by earnings until February, 1919. Since then there has been another sharp divergence to the disadvantage of the worker.

A STUDY OF TRAUMATIC HERNIA, SO-CALLED, AMONG RAILWAY EMPLOYEES

By C. W. HOPKINS, M.D., F.A.C.S., CHIEF SURGEON, CHICAGO & NORTHWESTERN RAILWAY, CHICAGO, ILL.

IN the discussion of traumatic hernia, the inguinal type being the most common, it is at once assumed that indirect inguinal hernia is referred to when the subject is presented. This is the type of hernia which is giving more and more concern because of the increasing number of claims of injury presented by a certain class.

Perhaps at no time in the history of railway surgery have so many

claims been made on account of alleged traumatic hernia as at present, and there is seldom a time when a railway company is not taking care of a score of so-called traumatic hernia cases among their employees and patrons. Willing as the companies are to do justice to these cases, the interesting standpoint to them lies in the prevention of fraud and of abuse of their good will.

It is not intended to consider any of the conditions which involve a loss, destruction, or solution of continuity of the tissues of the abdominal wall, where there is *prima facie* evidence of a traumatic lesion, but to limit this discussion to the consideration of the most common hernia, the oblique inguinal. The claim that the oblique inguinal hernia is the most common is partly based upon the observations of Professor Paul Berger, who in 13,483 hernias found 12,283 of the oblique inguinal type.

Traumatic Hernia Rarely Encountered

Reference to some of the older writers, as well as to many of the writers of the present day, shows that they consider true traumatic hernia one of the rarest conditions encountered in emergency surgery. Golebiewski has written a book on the workings of an association of trades, in which are made exhaustive studies of all of the various injuries, and the percentage of disability which such injuries or deformities occasioned estimated. In this book the subject of hernia is very thoroughly discussed, and he considers

Hernia results from a developmental defect and accidental injury can be only a secondary cause.

So many unjust claims are allowed under present conditions that the law should take cognizance of the fact, and definitely settle the matter.

The only protection possible at the present time is the routine examination of all employees for record of their physical condition at time of employment.

If rational interpretation in such cases is not made, workmen with this inherent weakness will have to be excluded from certain industries.

traumatic hernia to be such a rare condition that he recites in detail only two cases conceded by him as being primarily or indirectly traumatic hernia.

The subject of hernia is classified in this way: hernia occurs at a defective point; a trauma is very rarely the cause of this weakness; on the contrary, it is practically always congenital in which instance the trauma, to use the language of the author

mentioned, "is the means of the discovery rather than the cause of the hernia."

A shade of difference is made in the forms of traumatic hernia, distinguished as "True Traumatic, and Accidental." In the former, the blow or strain has been such as to force the hernia through the peritoneal covering, and in the latter the peritoneum is carried ahead; but both must remain under the general appellation of traumatic hernia, as they only represent a degree in trauma.

Personally, the more we see of these cases of so-called traumatic hernia, with the alleged ease of their acquirement, and with the absence of the symptoms that should have presented at the time the hernia is said to have been received, the more firm is our conviction that the actual occurrence of true traumatic hernia, in the average individual who comes before us, is rarely, if ever, seen.

Alleged Causes Inadequate

Men of various occupations, in railroad work in particular, present themselves three or four days, a week, or even two weeks or more, after an alleged injury, claiming that the hernia was acquired at the time of a "strain," a mis-step, a squeezing, an over-lifting, a fall, or a blow. They state that the hernia was not noticed at the time—not until some days later, or perhaps while in the bath. They may further state that no pain was felt at the time of the supposed accident, nor was there any shock, vomiting, or disability; in fact,

there was no loss of time from the date of the alleged acquiring of the hernia to the time they report to the physician. They also claim that they never noticed this swelling before, and are quite certain that the cause they allege must be responsible for it.

In the majority of cases examination reveals that there is a well developed hernia, sometimes even with old marks of a truss, and many times a scrotal hernia of large size. During the examination no soreness in the part, no ecchymosis, no effusion into the tissues are discovered nor is there the least tenderness upon palpation or rigid examination. The patient himself will assist in reducing the hernia in the most expert and experienced manner. It is easily reduced without pain or discomfort to the patient and readily returns upon standing. A large majority of cases show a large, patent ring on the opposite side and close examination of that side will disclose an impulse upon the examining finger when the individual coughs.

Even when a case is examined but a few hours or days after an alleged injury, and the vague history and lack of acute symptoms indicate that the real cause of the condition is an inherent one, it is useless to try to convince such patients that every man who develops this condition was born with potential hernia. Undertake to convince them that the condition is an old one, as they are well aware, and they will leave the office and go to their family physician, who will often agree with them in every detail, and back them up even upon the witness stand, testifying that the alleged hernia could have occurred and actually did occur as the patient claims, regardless of the absence of any accompanying symptoms that would necessarily have presented in the presence of true traumatic hernia.

Not Incident to Muscular Strain

No doubt there are cases of true traumatic hernia, but in railroad surgery in particular, which calls for the care of patients who have received severe falls or squeezings through the abdomen and pelvis, causing most extreme intra-abdominal pressure, sufficient to cause rupture of the bladder, kidney, liver, intestines, or to crush the pelvis, why is it that inguinal hernia is never found as a concomitant unless the injuries were probably of sufficient severity to cause death?

Taking into consideration the fact that there are thousands of men of all ages who are engaged every day in occupations requiring heavy lifting, hard straining, or are engaged in acrobatic work, which frequently calls for the most strenuous

effort and muscular action, particularly of the abdominal muscles, and who sustain severe falls, if extraordinary muscular effort or great intra-abdominal pressure are the chief causes of hernia, why are not all of these men victims of hernia? Nevertheless, the average individual expects the surgeon to believe any statement he wishes to make, and will try to convince him that a well developed hernia, with the necessary sac of peritoneum, reaching well down into the scrotum, occurred but a few hours or days before, without any marked symptoms, and with no disability on his part up to the time he comes for examination.

One interesting phase of this claim of traumatic hernia is that in such men as engineers, conductors, firemen, brakemen, crossing flagmen, section foremen, special police, and the dining car employees of a railroad, who have passed an examination before entering the service, the claim of traumatic hernia amounts to less than 1 per cent; on the other hand, the foreigner, such as the Greek, the Italian, the Pole, and other men who do not have the preliminary examination before being admitted to the service, comprise 99 per cent of the cases of alleged traumatic hernia. We feel sure that the 1 per cent of the men who have been examined for service who do appear with so-called traumatic hernia, had enlarged rings with a preformed sac that could not be felt or demonstrated at the time of the examination, or they would not have developed a subsequent hernia.

Hernia Incidence in Foreigners

As to the frequency of hernia among foreigners, it is significant that several years ago, when the law went into effect requiring monthly examination for occupational diseases of the men of a certain plant who were employed in the paint shops and other departments where chemicals were used, the first examination of 186 men revealed the fact that 48 of them had either single or double hernia of long standing. All of these men were foreigners and entered the service without physical examination. If during their term of employment before this examination, they had sustained any kind of an injury, they probably would have claimed that the hernia was received at that time.

It is a known fact that a prominent surgeon in Chicago, who does the medical and surgical work for a Greek society, performs more operations for the cure of hernia in one particular hospital than the rest of the entire staff combined. Whether the people from southern Europe inherit this weakness, or whether it is due to their habitual wearing of belts is a matter of discussion.

among some of our most prominent writers on the subject. In our own experience in railroad surgery, the files disclose that the vast majority of operations performed for hernia are among this class of European laborers, and my own observations lead me to believe that the condition is a congenital or inherited weakness of the parts, precipitated by pre-senility or disease which is so commonly found among them.

Structural Defects and Hernia

When the parts are exposed at operation, these cases usually present very thin oblique muscles with a very thin transversalis fascia, the fibers very closely held together, with an absence of the conjoined tendon and normal external ring, and a mere oblong or triangular slit instead of the normal ring. This makes it necessary to handle all of these tissues very carefully to get even a fair amount of tissue with which to remedy the congenital defect sufficiently to prevent recurrence. We do not find induration, effusion into the tissues, or rupture of peritoneum; but a smooth, tough, elongated culdesac, snugly lying along the cord, closely covered by fascia. In many instances a certain amount of omentum or bowel lies within the sac and may be adherent to it throughout its entire length.

There are cases which present a well defined double sac, called the pantaloons sac, and occasionally three sacs, coming off from the base at the internal ring. Many of these cases operated upon forty-eight hours after the alleged injury, will disclose the above conditions, and in spite of the claim of recent injury, there is no extravasation of blood or serum, nor the slightest laceration of tissue. There is, however, a thick, smooth, tough, adherent sac which must have existed from birth and has depended upon a series of repeated blows or impulses by the abdominal contents in forcing their way into the canal, carrying the preformed sac ahead of them, and which was the predisposing cause for some unusual force to bring them down sufficiently to make the hernia apparent and to cause more or less discomfort in breaking through adhesions a little beyond the long existing, slowly acquired, beaten path.

However, in the state of chaos which exists on account of the various opinions and contentions regarding traumatic hernia it has been considered best, by most employers, to have these cases operated upon as the best means of settling a difficult matter. There are numbers of would-be medical experts who will take the stand and swear to the possibility of a large hernia being acquired in the manner and at the time it is alleged by the patient. It also seems to be a settled fact that

the claimant will be given a verdict by the average jury, regardless of the merits of the case, or the facts presented by the defense, and as the matter now stands to contest such cases would entail much fighting and undesirable publicity.

Within the last few months the author has had three patients in particular with alleged traumatic hernia, supposed to have been received but a few weeks prior to examination and operation, and who claimed to have received the hernia while lifting a can of milk, while using a crow bar, or while lifting a hand car. None of these men had taken the preliminary examination for the service. Upon operation no external or internal ring or any well defined sac could be found but there was a large, general bulging of the whole abdominal wall on that side which showed that the entire canal had been obliterated by the general weakness of the entire abdominal structure, forming one large opening, and allowing the formation of a large peritoneal sac or pouch, the contents of which had to be reduced and the sac or pouch ligated in sections, and the entire abdominal wall in that locality rebuilt in order to obtain a satisfactory result. These cases all claimed to have been injured but a short time previously, but there was not the least sign of the recent injury which necessarily would have been present if the condition had been created at the time alleged.

Company Buys a Hernia

In connection with the cases just mentioned it may be permitted to relate an incident which occurred recently when about to operate upon a Greek, sent to Chicago to be operated upon for a hernia which was supposed to have occurred about one week previously. When the case was reported by the local surgeon, we wrote back and stated that from the facts in the case it was certainly an old hernia, and directed that he be sent to us for examination and operation. When about to operate upon the case, we informed him that a hernia existed on both sides and that we would correct them both at the same time. Although there was a hernia fully as large on the other side, he strenuously objected to an operation on that side, and wished operation on the left side only. When the sac was exposed, it was found to be very large, tough, and, as mentioned by C. H. Mayo, made up of heavy fibrous bands, which is a positive proof of a sac of long standing. After the operation was finished, and while he was coming out of the anesthetic, his straining and coughing produced a condition on the right side which was equally as large as the one just corrected, and upon which he would not permit an operation. This man had been in the service

but a short time, and as he is on record as having the right inguinal hernia which he would not permit us to correct, he will in all likelihood soon appear in a hospital of another railroad to be operated upon for an old hernia which he has compelled them to buy.

Proof of Accident Necessary

It has been decided by the surgical staff of some of the European armies, that unless a man had witnesses to his accident, had presented definite and immediately disabling symptoms, the claim of traumatic hernia will not be recognized or allowed. On this side, however, there are many surgeons who still claim that a man can receive traumatic hernia, yet present no such symptoms, as shock, vomiting, pain, etc., and that after the alleged receiving of the hernia he can work continuously up to the time he presents himself for examination or operation. They will give him a certificate to his employer to that effect, and such claims are being allowed by the courts and the compensation boards every day.

Consequently, the larger corporations are beginning to examine every man already in their employ to obtain a record as to his physical condition, and are demanding that every man who applies for employment be examined before being put to work, so that they can protect themselves against this claim for traumatic hernia which is being made against them, when in many instances, there is not the slightest history of any injury to the employee, or even a record of any accident. The matter must be definitely settled one way or another, sooner or later. No corporation, combination of corporations, or insurance companies will be able to do it; but it will have to be settled by the law, after it has been threshed out sufficiently to convince the law makers of the real conditions and facts. If this is not done it will ultimately work a hardship upon the very man that the law is seeking to protect, as the average workingman or laborer, who has hernia, will be either eliminated or kept out of employment. This same man, who is usually the laborer, rarely has sufficient money ahead to pay his expenses at a hospital and to have a competent surgeon for an operation with the only result that they are bound to overload our public institutions, increasing the burden upon the taxpay-ers in order to correct an old condition so that they can obtain employment and become self-sus-taining.

The History of a Hernia

We are all familiar with the embryonic forma-tion and the placing of the testicle in its proper position, and how Nature is supposed to close the

ring about the time of birth, and how she sometimes fails, as is proved by the development of inguinal hernia in children only a few weeks or months old. If this is fully understood, it cer-tainly is not difficult to see why a man develops hernia, and that every man who does develop hernia in later life must have been born with potential hernia, only waiting for the proper time and conditions to make its appearance, and for which the employer or insurance company would be expected to pay. They should not pay for inguinal hernia any more than they should pay for protruding hemorrhoids, which we know take time and certain conditions to make their debut into the outside world.

Many surgeons have gone so far as invariably to operate upon both sides in case of hernia, even when nothing more than a large patulous ring is to be found on the other side, and, without excep-tion, the results justify the procedure. Since January 1, 1914, if the patient could understand English and the conditions could be fully explained to him, I have operated upon both sides. Even if the opposite side presents no symptoms other than a patulous ring, there is found a well marked, preformed sac, and in many cases the omentum or bowel is strongly adherent through-out the entire length of the sac, waiting for some unusual impulse to bring it down—an occurrence which would no doubt be considered traumatic hernia.

In cases of foreigners who could not speak English, it is our practice merely to operate on the one side, for such cases would consider the employer responsible for a double hernia if both sides had been operated, even when no complaint had been made of the other side.

One Basis of Compensation

We have taken the liberty of incorporating in this paper the ruling of the Nevada Industrial Commission, date September 26, 1913, on the subject of hernia:

"Medical science teaches and has taught for the past twenty years, that which is now accepted as a medical and scientific fact, cor-roborated as such by the foremost surgeons and anatomists of the world, that is, that hernia (or so-called rupture) is a disease ordinarily developing gradually, and which is very rarely the result of an accident.

"With the object of treating the subject of hernia justly to both employer and em-ployee, and in accordance with medical and scientific teachings and facts, the Commis-sion rules as follows:

"Rule 1. Real traumatic hernia is an in-

jury to the abdominal (belly) wall of sufficient severity to puncture or tear asunder said wall, and permit the exposure or protruding of the abdominal viscera or some part thereof. Such an injury will be compensated as a temporary, total disability, and as a partial, permanent disability depending upon the lessening of the injured individual's earning capacity.

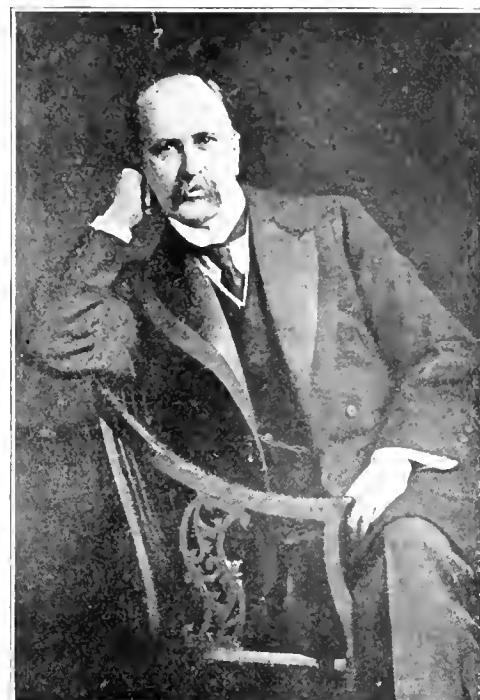

"Rule 2. All other hernias, whenever occurring or discovered, and whatsoever the cause, except as under Rule 1, are considered to be diseases causing incapacitating conditions or permanent, partial disability. But the permanent partial disability and the causes of such are considered to be shown by medical facts to have either existed from birth; to have been years in formation and duration, or both, and are not compensatory except as provided under Rule 3.

"Rule 3. All cases, coming under Rule 2, in which it can be conclusively proven: (1) that the immediate cause which calls attention to the presence of the hernia, was a sudden effort or severe strain or blow received while in the course of employment; (2) that the descent of the hernia occurred immediately following the cause; (3) that the cause was accompanied, or immediately followed, by severe pain in the hernial region; (4) that the above facts were of such severity that the same were noticed by the claimant and communicated immediately to one or more persons are considered to be aggravations of previous ailments, or diseases, and will be compensated as such for time and loss, and to a limited extent only, depending upon the nature of the proofs submitted, and the result of local medical examination."

Put Problem on Sane Basis

The foregoing is stated to following rulings in Ohio and Washington. The matter is a most important one as under the English law there has been the greatest difficulty over the subject; for this reason, and on account of the increasing frequency of these claims, especially in laborers from European countries, we are keeping a record of all hernia cases which record will include among other things, nationality, age, occupation, alleged cause of injury, state of health, and condition of rings on the opposite side. From this it is hoped to obtain statistics which will prove to be of value or at least of some assistance in helping to place this difficult problem upon a sane basis and to bring about sensible legislation where the employer and employee will both obtain a fair

deal and wipe out the condition of injustice. The present state of affairs certainly places a premium upon malingering and dishonesty in a certain class.

SIR WILLIAM OSLER—1902

SIR WILLIAM OSLER—A REVIEW AND AN ANNIVERSARY TRIBUTE

The month of July, 1919, marked the seventieth anniversary of the birth of Sir William Osler, and the *Bulletin of the Johns Hopkins Hospital* commemorates the occasion by devoting a full issue to recollections of Osler in Baltimore. There is no doubt that Osler stands out as the most prominent figure in clinical medicine during the years he occupied the chair at Johns Hopkins. As physician, teacher, investigator, pathologist, student, public citizen, and literateur, Osler's position was, indeed, unique.

Clinical Instruction at Bedside

In these days when the orderly arrangement of clinical facts and deductions has been taken for granted, and the mind of the investigator is turned to the fields of biochemistry and physics for help in the solution of medical problems, it may be somewhat difficult to appreciate Osler's tremendous contributions to medicine in the latter part of the nineteenth century. Personally an investigator, primarily in the fields of the natural sciences and then in pathology, always viewing his problem from the standpoint of the patient, Osler brought the fruit of his investigations into direct contact and association with the patient.

Likewise, as a teacher he brought to this country the lessons learned in the clinics of England and the continent and made the medical wards at Johns Hopkins the first spot in this country where the newer medicine was taught. As Thomas says, he put the students into the wards but he did not leave them there, he stayed with them and gave them clinical instruction on a uni-

versity basis. As the organizer and director of the medical clinic in Baltimore, and as teacher, Barker and Thayer speak of Osler in terms which to be appreciated must be quoted.

Barker believes that Osler's arrangement of the hospital medical staff into two grades, as senior residents and the junior interns, was responsible in great part for the success of Osler's new ideas. This arrangement permitted the introduction of more extensive and systematic courses of instruction in the practical technical methods of gathering data regarding disturbances of structure and function in the sick than had before been customary. Barker also thinks that the use of the fourth year students as clinical clerks in the wards of the hospital was one factor in the success of the Hopkins Hospital as a teaching institution. The comment is apparent that even today universities, attempting to give their medical students the best of instruction, seek often fruitlessly to emulate the example Osler set in the early nineties.

The Personality of the Teacher

But all of these formal objects are only part of Osler's record as a teacher. Students in the Hopkins Medical School during Osler's régime are much more apt to associate with the professor of medicine the powerful personal magnetism and the tremendous influence of Osler's personality on the young student. Thayer, in particular, has brought out some of the dicta and modes of expression which Osler used to hammer thoughts into the minds of his students. As a teacher, all felt that he was likewise a student and a worker with the young men he was teaching. His well known and oft repeated remarks about the causes of aneurysm stick forever in the minds of those who have heard him refer to Bacchus, Mars, Venus, and Vulcan. And many a young fellow was inspired to do better work because of the hearty clap of Osler's newspaper on his back as he walked down the street.

His Knowledge of Foreign Literature

Osler never forgot information given him by his younger associates, whether from physician or student in his wards; and if subsequently an article were to be published, the man who mentioned in the street-car a case of interest would very likely find his name printed in the article as having referred, no matter how many years before, to this particular case. Many a man leaving Osler's clinic has uttered thanks for his insistence, even in student days, of a knowledge of the medical literature of other countries. Teachers today might well follow Osler in devoting a part of each big clinic to a student review of an important article from the French, or German, or Italian literature. Although this tendency of Osler's clinic was, perhaps, definitely associated with his sense of literary values, his students appreciated in later years the purely scientific necessity of a knowledge of foreign literature in investigative work.

A Master of Morbid Anatomy

MacCallum makes a statement which should be quoted in full, "The statement may be safely ventured that no clinician in English speaking countries has had at his command such a wide and detailed knowledge of morbid anatomy as Osler. There may be different opinions as to the reasons for his greatness as a teacher, as a man among men and in other ways, but hardly more than one opinion as to the foundation of his greatness as a clinician."

Some of the collected pathological data of Osler, which unquestionably formed the ground-work of his text-

book of clinical medicine, are still used in the teaching of pathological anatomy. In fact, it can almost be said that Osler finished more pathological clinical connections than any other man. Although today we are turning for the explanation of the disease processes to the allied sciences of biochemistry, physiology, and physics, it is doubtful whether such steps could have been made without the tremendous amount of collected statistics of Osler and men of his type.

The Practice of Psychotherapy

Osler's relations to his patients have been spoken of by McCrae and can be best summarized in the statement that although Osler did not talk about psychotherapy he continually practised it. The writer of this review has seen Osler walk into the room of a patient with pneumonia in a state of *coma-vigil*, who for a week had been unable to recognize members of his own family, and who in response perhaps to Osler's cheery, "How do you do, Mr. X?" or, perhaps, in response to the waves of magnetism shooting from his personality, looked up, opened his eyes, and said, "How do you do, Dr. Osler?" The ward was always a cheerier place after Osler's visit, and one could feel the spirit, if not the voices, of the patients singing,

"God's in his heaven . . .
"All's right with the world!"

Like Louis Pasteur, Osler was interested in world welfare. As a citizen of Baltimore he was an earnest fighter for civic improvement, especially along the lines of public health. His interest in tuberculosis was as much sociological as medical. Perhaps more than any single man his influence was felt in the development of the state medical society and in the formation of a library. His readings were wide, his literary productions abounded in quotations from the classics. The style of his writings was as pleasing to the eye as his clinical discourses were to the ear.

The aptness of his expressions may be exemplified by recalling "The Master Word in Medicine." In this discourse to young doctors he speaks, as he has done frequently, of the necessity of a single hearted devotion to one's mistress in medicine, and advises the young medical man to put his "affections in cold storage." Yet this did not prevent him from teasing the sick medical student when walking into his room if he saw a pile of letters in a feminine handwriting on the young man's table.

Organize Medical Service

Through every single article in the *Bulletin* runs one thread of sentiment and thought; whether Osler is being discussed as pathologist, as teacher, as investigator, the writer of the article writes about him as of a deep and whole-souled friend. This ability to inspire friendship is the thing that everyone who came in contact with Osler felt most powerfully. The medical student on the street-car, matching coins with the chief to see who would pay, knew that Osler was his friend; and the country doctor, coming in with an undiagnosed disease, knew that Osler was his friend. He was square to his colleagues within and without his own faculty. He gave his young men every opportunity of self-expression and development, and he never took as his own the work done in his clinic, even at his suggestion by his younger associates. No wonder everyone loves Osler.

Success is for all who are willing to pay the price of admission, but there are no complimentary tickets.—A. Pike.

MEDICINE AND INDUSTRY

Hygiene, Sanitation, Medical and Hospital Service in Relation to Industry

OTTO P. GEIER, M. D., *Editor*

THE MEDICAL PROFESSION AND THE NEXT OUTBREAK OF INFLUENZA

THE members of the medical profession as individuals are in position to make more friends among the people at large than members of any other profession. They enjoy a respect generally accorded no other similar group of men. At some time or other almost every individual, either for himself or for a member of his family, has reason to put all of his faith and hope for life in the medical or surgical skill of some physician. Contacts are made and friendships formed which leave an indelible impress.

The same feeling of dependency comes to the community at large in times of serious epidemic. Then the community looks to the profession to save it from preventable illness and needless loss of life. This was the situation of the world at large during the recent epidemic of influenza, when the people stood aghast at the inroads of disease.

The massing of millions of men in army camps, and the marvelous control of some of the communicable diseases only serve to emphasize the helplessness of the profession in meeting the ravages of this world-wide scourge, influenza.

The conditions of the past year have produced an open state of mind in the public, looking towards definite control of public health. Another point of progress has been the recognition on the part of financial and business interests of the economic value of good health. The task of meeting demands for war production on an unprecedented scale put the workers to an exhaustive test of their physical fitness. Absence from work on account of illness loomed large in the failures on the part of manufacturing interests to meet their promised deliveries of munitions of war.

Occupational diseases, fatigue, the effect of overtime, and bad housing received due recognition as factors in schemes of production. Scientific studies along these lines have been stimulated twenty-five years in advance of the ordinary course of industrial events; all of which has

placed the financial and business world behind any sane constructive health program.

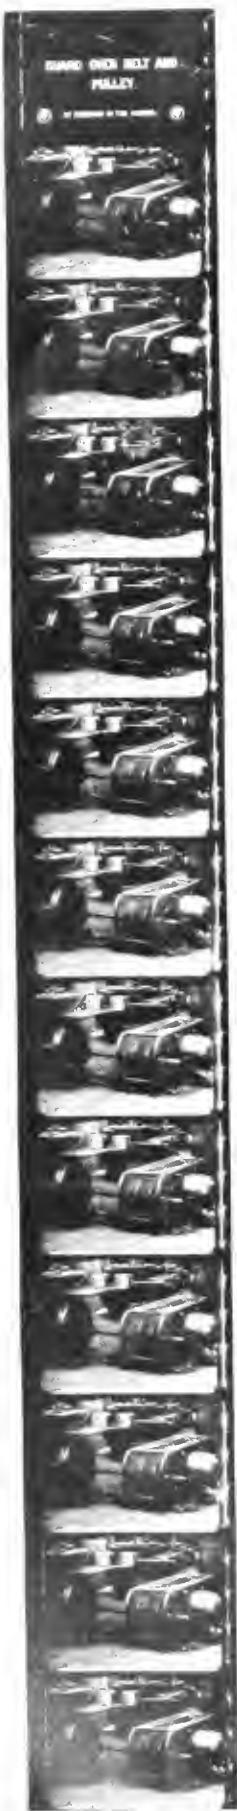

The question that is uppermost in forward looking medical minds today is this: Will the profession make use of the advanced outpost that it now holds in the public eye and its latent power for good, or will it ignore this most favorable opportunity of raising the standard of living of all the people through the better health conditions through centralized intensive health work? Will it be sufficiently socially minded to work as a unit for a broad national, state, county, and municipal health reorganization?

An initial test of our unity of purpose is now under way. The profession and the laity are at one in the opinion that some governmental action should be taken for the control of the next epidemic of influenza. The Harding-Fess Senate joint resolution No. 76 provides five million dollars "for the investigation of influenza and allied diseases, in order to determine their cause and methods of prevention." With an admitted economic loss approximating four billions from the last epidemic, the request for this amount of money is most reasonable.

In the present temper of the country, the passage of these two bills can easily be secured if the profession interests itself in their enactment. Every member of the American Medical Association should write a short letter to his Congressman and Senator in behalf of these two bills.

The officers of the various medical associations, national and state, will prove themselves unworthy of their trust if they do not become active, insistent proponents for these bills. It is for these groups to secure the interest and support of the business interests of the country in behalf of this legislation. Failure can be charged to them, and the public will be in no pleasant temper if some national effort is not under way when the next epidemic of influenza occurs. Are we petty in our social planning, or will we use our latent power?

EDITOR.

USES OF MOTION PICTURES IN INDUSTRIAL MEDICINE

BY LESLIE WILLIS SPRAGUE, DIRECTOR, INDUSTRIAL SERVICE SECTION, COMMUNITY MOTION PICTURE BUREAU, NEW YORK CITY

THIERE are humane as well as economic reasons for the wise use of every possible agency of industrial health. Sickness is one of the specters which stands at all times outside the workman's door ready to lead dire poverty in by the hand. The tragedy of sickness in the laborer's home, especially when the breadwinner is disabled, is one under which the millions groan.

The charity that relieves distress in times of illness, even the more just and considerate sick-and-accident benefit, is less wise and less benevolent than any measure which prevents actual need by keeping the workers in health and strength.

The average loss of work-time through sickness amounts, according to a recent study, to six days a year for each worker. This seems a very low estimate, yet to the employer as to the workers—and not less to the community—the statement suggests an economic loss which may profitably be considered in any discussion of expenses connected with health-education; and any expense connected with the use of motion pictures in industrial health-education may well be met out of the saving of labor-time lost through sickness and accident, leaving, as I believe, a very large balance on the credit side of the ledger.

Enemies to Industrial Health

Contagion, fatigue, and accidents are the three enemies to health and labor effectiveness which any promotion of industrial health must consider. Periods of epidemic, such as the widespread influenza of the autumn of 1918, make dramatic the need not only of industrial sanitation, but also of the wisest public opinion and the earnest personal cooperation in each industrial group in an effort to prevent the spread of disease. Industry is applying the lessons learned by army officers concerning venereal diseases and their methods of promoting an intelligent moral attitude toward vice.

Very much can be done by motion pictures to disseminate knowledge regarding contagion, and the necessity of self-protection and general cooperation on the part of workers against contagious diseases. The United States Army found "Fit to Fight" an effective weapon against the spread of venereal diseases not only among soldiers, but also in industrial plants. Far

*The second of a series of three illustrated articles by Leslie Willis Sprague describing the use of the motion picture in promoting interest in public health. The series includes articles on the following subjects: (1) "Motion Pictures in Public Health"; (2) "Uses of Motion Pictures in Industrial Medicine"; (3) "The Motion Picture in Industrial Disease." The first of the articles appeared in the August issue.

from satisfactory as are the motion pictures "Fit to Fight," and its companion, "The End of the Road," both devoid of all power of delicate suggestion, they have, nevertheless, proved the great possibilities to be achieved by motion pictures in health campaigns.

Many industrial communities are in need of serious sanitary reforms which, in order to be effective, depend upon the interest and personal cooperation of the workers. Tuberculosis, typhoid, and other threatening and devastating contagious diseases can be stamped out only by a vigorous and enlightened opinion in which all members of the community share. These subjects have been well treated by motion picture producers and there is available a rather adequate supply of films which forms the most effective health campaign an industry can possibly undertake.

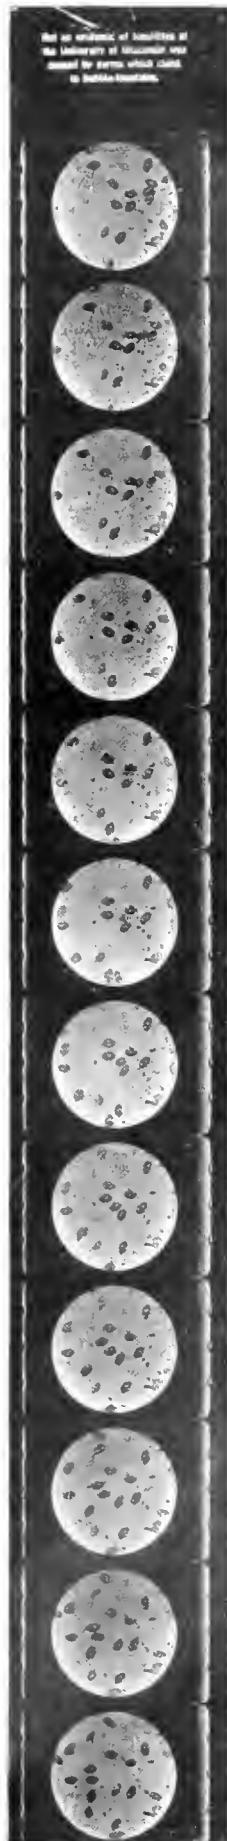

Relieving Fatigue

The subject of fatigue is one which needs more thorough study and a wider consideration by both workers and employers. Efficiency, the proper length of the working-day, and other matters vital to industrial progress and human welfare are involved in a mastery of this problem. It is safe, however, even now to say that unwise ways of work and foolish ways of spending the rest-hours, ill considered diet, the lack of adequate and proper recreation, physical and mental, lie at the base of some of the most serious losses which productivity sustains, to the detriment alike of employees, employers, and the general public. Instruction concerning proper diet, sleep, ventilation, and exercise can be given by motion pictures now available, even though a more adequate treatment of these themes should receive the attention of industrial leaders and motion picture producers.

Pictures presenting the appeal of athletics may successfully be used to develop activities along this line. Motion pictures may also be the means of stimulating country walks and other health-giving habits. Such pictures as "Ten-Minute Vacations" will be useful to the industrial manager who understands the value of organizing the rest-moments of his workers.

By the selection and projection of picture programs in the industrial plant or in the industrial community, it is easily practicable for the industrial manager greatly to further any particular reform or helpful project he may undertake, creating a general and effective interest in the measures proposed.

Safety first has assumed sufficient importance in many minds to call forth the safety engineer and the campaign expert who organize in different industries periodic campaigns in behalf of safety. Motion pictures have been put rather extensively into the service of safety campaigns, and there are many films which present information and make the needed appeal to the workers. Some of these films, for example, "Father and Son," emphasize the employer's responsibility and

Not an exhibition of facilities at the University of Minnesota was deemed necessary which could not be reproduced.

rquent neglect, and it would not be impertinent in some instances if the workers were to provide programs of such films for the education of employers. There are other films which convince workers of their need of mutual aid in adequate protection, different picture programs representing devices used in different industries. Any intensive campaign in behalf of safety is inadequately planned which does not make use of motion pictures as one of the means to secure the workers' interest and cooperation.

Much is still to be done in the production of motion pictures which will give, even to those who cannot read, the motive and the knowledge necessary to the promotion of industrial health; but more is to be done by the employment manager, the health officer, and the welfare secretary to utilize, in preventive and constructive ways, the

picture programs now available for the effective awakening and education of the workers in matters of contagion, fatigue, recreation, and safety.

The foreign language titles bring the motion picture appeal within easy reach of all nationalities. This is a matter of great importance to the dangerous occupations in which, often, the majority of the laborers are not English speaking.

Although constituting but one of the many profitable ways by which motion pictures can be applied in industry, their use in health propaganda is sufficient justification for the installation of motion pictures in every industry, particularly at this time when the utmost labor power of the nation is demanded for the sake of increased production and when humane considerations are urgently needed as a safeguard against social unrest.

ANILIN POISONING—ITS DIAGNOSIS AND TREATMENT

BY R. P. ALBAUGH, M.D., CLEVELAND, OHIO, FORMERLY DIRECTOR, DIVISION OF INDUSTRIAL HYGIENE, OHIO STATE DEPARTMENT OF HEALTH

ANILIN is one of the newer industrial poisons encountered in the United States and has been the cause of poisoning in the manufacture of anilin and its derivatives, in dyeing establishments, in the manufacture of rubber goods, in reclaiming rubber from scrap, and in using certain washes for printing press rollers. It is produced by the action of hydrochloric acid and iron fillings upon pure nitrobenzol. The poison may be absorbed through the skin by direct contact or from saturated clothing, by inhalation of vapors and impalpable dust, and also by way of the digestive tract. It is similar in action to the other amido compounds of benzol and its homologues, all being blood poisons causing the formation of methemoglobin with consequent "internal suffocation."

Symptoms.—In acute cases the symptoms vary from mild to severe. Although the onset of severe symptoms may be sudden, there is usually pallor of the skin and mucous membranes with slight cyanosis, a feeling of weariness and weakness, vertigo, unsteady gait, defective power of orientation, and tense, rapid pulse. A swarthy cyanosis rapidly develops with bounding pulse, air-hunger, lowering of sensibility, and bloody urine. Sudden prostration may occur with cold, pale, moist skin; blue lips, nose and ears; and weak, thready pulse, followed by convulsions, deep coma, and death. At first the urine is usually normal; later it becomes smoky to bloody in appearance.

In chronic cases, which occur less frequently, there are anemia, slowing of the pulse, digestive disorders, headaches, vertigo, unrestful sleep, and disturbances of sensibility.

Diagnosis.—The importance of blood examination in the diagnosis is evident when it is considered that usually there are an increase in number of red blood cells with loss of hemoglobin, a low color index, degeneration and imperfect regeneration of red corpuscles, a decrease in polymorphous leukocytes, and an increase in lymphocytes. In the absence of blood examination it is usually sufficient to observe the cyanosis, the dark colored urine, the odor of anilin in the breath, the rapid pulse, the dyspnea, and the nervous symptoms, and the history of exposure.

Prognosis.—Many men working in anilin constantly seem to acquire a tolerance to it, but if symptoms once manifest themselves, there is usually a hypersensitiveness to the poison. Recovery in the initial milder cases is usually prompt, while symptoms in the severer cases may not subside for several weeks. It is good practice, therefore, to advise patients against re-exposing themselves.

Treatment and Prevention.—Persons exhibiting symptoms of anilin poisoning should be given the benefit of fresh air at once. If anilin has come in contact with the skin or clothing, the clothing should be changed at once and the body flushed with cool water. Oxygen may be administered in connection with artificial respiration.

In severe cases, heart stimulants are indicated, especially camphorated oil. Alcohol should be avoided. Prevention depends upon effective ventilation to prevent the inhalation of fumes, the

handling of anilin and attire of workmen in such a way as to prevent contact with the skin, and provisions for the prevention of ingestion of anilin.

MEDICAL BENEFITS AND THE MEDICAL PROFESSION UNDER WORKMEN'S COMPENSATION LAWS

BY CARL HOOKSTADT, UNITED STATES BUREAU OF LABOR STATISTICS, WASHINGTON, D. C.

WORKMEN'S compensation laws usually provide two kinds of benefits—money benefits and medical treatment, the liberality of which vary greatly among the several states. Of the forty-five compensation laws enacted in the United States up to July 1, 1919, only six¹ place no limitation except reasonableness upon the amount of medical treatment which the employer must furnish in cases of industrial accidents. The laws of Alaska, Arizona, and New Hampshire provide no medical service whatever except that in fatal cases involving no dependents the medical expenses of the last sickness shall be paid by the employer. All of the other laws limit the employer's liability either as to length of time or amount, or both. Table I shows the medical benefits provided under the several compensation laws in the United States.

Kind of Service

Most of the states provide that "reasonable or necessary medical, surgical, and hospital service" must be furnished, leaving the question of reasonableness or adequacy to the commissions or courts to determine. Thirty states include medicines within this provision; 18² include surgical appliances and supplies; 10³ include nursing; while Nevada, Oregon, Washington, and the Federal Government include transportation.

It must not be understood, however, that the

What is the best solution of the medical fee question under workmen's compensation laws?

Should the employer or the employee have the right to select the physician in industrial accident cases? And should this privilege be exclusive or restricted?

How may the burden of cost for medical and hospital services under compensation acts be equitably distributed?

How have the various states dealt with these and other questions of like gravity? The comprehensive survey of policies in all states presented herewith will help to answer some of these questions.

and thereby reduce their compensation costs.

Although adequate medical treatment is absolutely essential to complete rehabilitation and restoration of an injured employee's earning capacity only six laws, as already noted, require the employer to furnish unlimited medical service. Several states make no provision whatever for medical treatment, while in others the low maximum limits make adequate treatment impossible. Some idea of the inadequacy of the medical service provisions may be obtained from a study of the severity of industrial accidents as shown in Table II.

Two Weeks' Care Inadequate

The Nevada data includes all non-fatal accidents while the other states cover only temporary disabilities. Using the Washington statistics as the criterion, it will be seen that in those states which limit the medical service to two weeks⁴ about 68 per cent of the accidents are inadequately provided for, and even in the 90-day states⁵ 7 per cent are insufficiently provided for.

The inadequacy of medical service due to statutory time limits is still further increased in some states by limitations upon the amount or cost of treatment which employers are required to fur-

³ California, Idaho, Indiana, Kansas, Kentucky, Maryland, Nevada, New York, Ohio, and Utah.

⁴ Delaware, Montana, New Mexico, and Vermont.

⁵ Kentucky and Michigan.

nish. These maximum limitations range from \$50 in Montana and New Mexico to \$500 in Utah. The effect of such limitations may be seen from an investigation of medical costs of accidents made by the Ohio industrial commission in 1913. This study disclosed the fact that in 20.6 per cent of the permanent disability accidents the medical costs per case were \$50 or more; in 8.6 per cent the costs were \$100 or more; and in 2.6 per cent the costs were \$200 or more. The corresponding percentages for fatal accidents were 26.6, 13.3, and 6.7, and for temporary disability accidents (over 1 week), 2.2, 0.6, and 0.1. In several of the states the maximum limit is high enough to cover practically all except the more serious injuries, but it is in the severe injury cases that the workmen's needs are greatest.

This failure to provide adequate medical service seems to indicate not merely the opposition of the employers but to reflect the inability of society to comprehend the great importance and social value of the speedy restoration of the earning capacity of injured workers. The benefits provided for in compensation laws, instead of being regarded as a means of effecting rehabilitation, have been considered as an end in themselves. Compensation commissioners have too often been satisfied with the performance of their duties merely if the benefits provided in the acts have been paid in accordance with the statutory requirements.

Selection of Physicians

Should the employer or the employee have the right to select the physician in industrial accident cases? And should this right or privilege be exclusive or restricted? These mooted questions have in recent years received a great deal of attention in the workmen's compensation field. The subject is particularly important because it directly affects the employee, the physician, and the employer. The employee is interested in his own speedy recovery and in having a physician in whom he has confidence; the employer is interested in reducing his compensation and medical costs; and the physician is interested both financially and professionally. The interplay of these various and sometimes conflicting interests constantly causes friction and creates innumerable difficulties.

The statutory provisions and actual practices as regards selection of physicians are as follows: In eight states injured employees are granted the right to select their own physicians at the employers' expense. In four of these states¹ this right is granted specifically in the act, while in

four states² the employee is granted this privilege by virtue of rules or interpretations of the administrative commission. In addition, Nebraska permits the employee to choose the physician in dismemberment or major surgical operation cases, and the Texas act allows the employee to

TABLE I
AMOUNT OF AND CONDITIONS FOR MEDICAL SERVICE UNDER COMPENSATION LAWS

State	Period	Medical and surgical aid	
		Maximum amount and other qualifications	
Alaska	-----	Only in death cases involving no dependents; maximum \$150 for medical expenses between injury and death.	
Arizona	-----	Reasonable medical and burial expense in death cases involving no dependents.	
Cal.	Unlimited	Such service as reasonably required.	
Colo.	30 days	Maximum \$200 unless there is a hospital fund. Special operating fee of \$50 in case of hernia; also dental service, maximum \$100.	
Conn.	Unlimited	Such service as deemed reasonable by attending physician. Special provision for seamen on United States vessels.	
Del.	2 weeks	Maximum \$75.	
Hawaii	-----	Maximum \$150.	
Idaho	Unlimited	Reasonable service for reasonable period. Hospital benefit fund may be permitted in lieu of statutory provision.	
Ill.	8 weeks	Maximum \$200; full hospital service while compensation is payable; full medical and surgical aid as long as hospital treatment is required.	
Ind.	30 days	Such service as deemed necessary by attending physician or board. Employee must accept unless otherwise ordered. 30 days additional treatment if necessary in opinion of board.	
Iowa	4 weeks	If requested by employee, court, or commissioner; maximum \$100; \$100 additional in exceptional cases.	
Kansas	50 days	If demanded by employee; maximum \$150.	
Ky.	90 days	Unless board fixes other period. Maximum \$100, or \$200 for hernia operations.	
La.	-----	Reasonable services unless employee refuses to accept; maximum \$150.	
Me.	30 days	Maximum \$100; additional service if nature of injury requires.	
Md.	-----	Such service as may be required by commission; maximum \$150.	
Mass.	2 weeks	Longer in unusual cases at discretion of board	
Mich.	90 days		
Minn.	99 days	Maximum \$100; upon request of employee, court may allow additional treatment if need is shown.	
Mo.	8 weeks	Maximum \$200.	
Mont.	2 weeks	Unless employee refuses; maximum \$50 unless there is a hospital fund; special operating fee of \$50 in case of hernia.	
Neb.	-----	Unless employee refuses; maximum \$200; employer not liable for aggravation of injury if employee refuses to accept.	
Nev.	90 days	Time may be extended to 1 year by commission; transportation furnished.	
N. H.	-----	Medical service and burial expenses only in death cases involving no dependents; maximum \$100.	
N. J.	4 weeks	Unless employee refuses; maximum \$50; in unusual cases bureau may extend period to 17 weeks but not over \$200; special operating fee of \$150 in case of hernia.	
N. M.	2 weeks	Maximum \$50, unless there is a hospital fund; special operating fee of \$50 in case of hernia.	
N. Y.	60 days	Such service as may be required or requested by employee.	
N. D.	Unlimited	Such service as nature of injury may require.	
Ohio	-----	Such service as commission deems proper; maximum \$200, except in unusual cases.	
Oklahoma	-----	Practically unlimited service.	
Oregon	-----	Includes transportation; maximum \$250; commission may allow additional service.	
Pa.	30 days	Unless employee refuses, in which case employer not liable for aggravation of injury; Maximum \$100, except in hospital cases.	
P. R.	Unlimited	Necessary medical service and sustenance as prescribed by commission.	
R. I.	4 weeks	Maximum \$100.	
S. D.	4 weeks	Longer at option of employer; employee must accept; maximum \$100.	
Tenn.	30 days	Two weeks additional in hospital cases.	
Texas	2 weeks	Maximum \$500; hospital benefit fund permitted in lieu of statutory provisions.	
Utah	-----		
Vt.	14 days	Maximum \$100.	
Va.	30 days	Such service as deemed necessary by attending physician or commission; longer at option of employer. Employee must accept unless otherwise ordered by commission.	
Wash.	Unlimited	Transportation included; employees must contribute one-half medical cost.	
W. Va.	-----	Maximum \$150; \$300 in severe cases; \$600 in permanent disability cases where disability can be materially reduced.	
Wis.	90 days	Maximum \$100.	
Wyo.	-----	Commission shall furnish necessary medical service for reasonable period unless employee refuses; transportation furnished if necessary.	
U. S.	Unlimited		

¹ Colorado, Massachusetts, Rhode Island, and Washington.

² Nevada, Ohio, Oregon, and Vermont.

select the physician if the employer, having engaged a contract physician, fails or refuses to file the contract agreement with the industrial accident board. The laws in five states⁸ grant the employee the right to select his own physician—at the employee's expense, however.

In twenty-one states⁹ the employee is given the right to select the physician at the employer's expense if the latter neglects or refuses to furnish competent medical care, or in an emergency.

Change of Physicians Permitted

Seven states¹⁰ authorize the administrative commission to order a change of physicians if the medical service furnished by the employer is incompetent or inimical to the injured employee. In Washington, also, the state medical aid board, by rule, reserves the right to transfer a man for treatment to a surgeon when it becomes evident that the injured workman is not receiving the service that he should at the hands of the physician of his choice.

In all of the other states which provide for medical service in case of injury, the employer or his representative, the insurance carrier, has the right to select the physician. Most of these laws, however, make no specific provisions as to the selection of physicians, but the courts and commissions generally hold that the obligation of the employer to "furnish" or "provide" medical service carries with it the privilege of choosing the physician. This practice has been based on two theories: First, that the employer is more competent to judge the efficiency of the doctor employed and to provide efficient medical and hospital treatment; and, second, that it is to the interest of the employer to furnish the very best medical and surgical treatment, so as to minimize the result of the injury and to secure as early a recovery as possible. As a matter of practice, however, in quite a large percentage of cases the employee is allowed to choose his own physician, but the extent of this practice depends upon the policy of the employers and insurance carriers. The large employers, especially those having an organized medical service within their establishments, generally insist upon their legal right to select the physician.

No state compensation law makes specific provision for a panel of physicians from which a choice is to be made. California, however, has an incipient panel system, as shown in the following statutory provision: "If the employee so

requests, the employer shall tender him one change of physicians and shall nominate at least three practicing physicians competent to treat the particular case, or as many as may be available if three can not be reasonably named, from which the employee may choose; the employee shall also be entitled, in any serious case, upon request, to the services of a consulting physician to be provided by the employer; all of said treatment to be at the expense of the employer. If the employee so requests, the employer must secure certification by the commission or a commissioner of the competency for the particular case of the consulting or additional physicians." The foregoing provision does not apply, however, to employers' establishment hospital funds approved by the commission.

A majority of the medical profession thus far seem to be opposed or at least apathetic toward the panel system. On the other hand, quite a number of state commissioners and members of the medical profession, especially those who have been in close touch with the administration of compensation laws, have come to the conclusion that some check upon free choice, exercised either by the employee or employer, is necessary.

Moreover, under the present system of selection by the employer, it is not an uncommon practice in some states to allow employees to choose a physician from a panel nominated by the employer or insurance carrier.

Why Employer Should Select Physician

Inasmuch as the burden of paying the medical costs rests upon the employer, it seems reasonable that he should have a voice in the selection of the physician. He is naturally interested in reducing his compensation costs. This reduction depends to some extent upon the speedy restoration of the injured employee's earning capacity, which in turn is dependent largely upon the adequacy of the medical and surgical treatment furnished. Competent medical treatment, however, is not always possible if the selection of the physician is beyond the control of the employer, who is, as a rule, more competent than the injured employee to judge the efficiency of the physician. The foreign, non-English speaking, and not infrequently illiterate workman naturally chooses a physician

⁹ Connecticut, Delaware, Hawaii, Idaho, Illinois, Indiana, Kansas, Kentucky, Maine, Maryland, Minnesota, Nevada, New York, Oklahoma, Pennsylvania, South Dakota, Tennessee, Texas, Virginia, and Wisconsin.

¹⁰ California, Connecticut, Kentucky, Missouri, Nevada, Texas, and Virginia.

of his own nationality, who is often incompetent and sometimes disreputable. Some of these physicians not only attempt to mulct the employers by prolonging treatment, making unnecessary calls, padding their bill, and overcharging generally, but because of their incompetency are an actual menace to the patients themselves. Numerous cases are on record in which injuries that should have had the attention of highly skilled surgeons were treated by physicians without surgical practice and wholly incompetent. Such treatment is always costly to the employer and frequently harmful to the injured workman.

Because of these conditions many employers and insurance carriers have insisted upon their legal right to select the physicians, and the tendency to exercise this right seems to be on the increase. Most of the large manufacturing establishments, and even some of the insurance companies, have established hospitals in connection with their plants. It is maintained that more efficient medical service can thus be rendered at much less cost. Furthermore, it allows closer medical supervision. A common complaint made by employers is that workmen will not report minor injuries, many of which become septic and develop into serious cases. The prompt attention given to injuries and the close personal supervision made possible through an establishment hospital minimize the danger of blood poisoning and result in earlier recoveries. It is also maintained that malingering can be better controlled and prevented when the employer has supervision over the medical service furnished.

Why Employee Should Select Physician

On the other hand, during the last two or three years, there has been a widespread reaction against the present system of selection by employers, and it may well be asked: Why this reaction if the system is as beneficial as is maintained by its advocates? Three reasons are generally advanced in favor of free choice of physicians by employees.

In the first place, the free and unhampered choice of one's own physician has generally been considered as one of the inalienable rights of mankind. The relationship existing between a patient and his physician is private and personal. Furthermore, the therapeutic value of confidence and faith in one's physician is well recognized by the medical profession, and this confidence naturally is assured when the injured workman selects his own physician. Moreover, the injured man has most at stake. It is he, and not the employer or physician, who suffers; it is his life which hangs in the balance. A man desires a doc-

tor whom he knows, with whom he can freely and unreservedly discuss his ailment, and in whom he has confidence.

Another factor which has influenced the movement for free choice has been the dissatisfaction with the kind of medical service frequently furnished by employers and insurance carriers. While it is true that many employers maintain excellent hospitals with highly skilled surgeons and trained nurses in charge and provide medical treatment even in excess of statutory requirements, this is by no means the general practice. The kind of service furnished by many employers, and particularly by some insurance companies, is entirely inadequate. There has been an increasing tendency to employ contract doctors, many of whom have not been especially competent. Furthermore, physicians employed on a contract basis frequently have more cases than they can take care of properly and in addition are not inclined to give them the same personal attention as would be given by physicians engaged directly by the employee. The evils and abuses of this contract system have been repeatedly pointed out and condemned by compensation commissions and the medical profession.

Returning the Patient to Work

Another important problem is to determine when the injured workman has sufficiently recovered to be able to return to work. Obviously it is to the employer's interest to reduce the disability period as much as possible, and frequently this fact influences unduly the decision of the employer's physician, especially if employed on a contract basis.

The third factor in the movement for free choice has been the opposition of the medical profession to the medical practices of the employers, and particularly of the insurance companies, which have developed under the compensation laws. Physicians have demanded their regular rates—those which they had charged before the advent of workmen's compensation laws. Insurance companies, on the other hand, have insisted that the increased security of payments under compensation and the economic and financial status of the injured employee should be taken into consideration in determining the reasonableness of fees for medical and hospital services. There has also been a tendency on the part of some physicians to pad their bills and raise their rates. As might be expected, such a condition immediately resulted in numerous and acrimonious disputes, between the medical profession on the one hand and the employers and insurance carriers on the other, as to medical fees. The

compensation commissioners were usually able to effect a working compromise, but such compromises have on the whole been unsatisfactory. Insurance companies have refused to pay medical bills unless they were satisfactory, and physicians in retaliation have threatened to refuse to treat industrial cases unless guaranteed their regular rates. As a counter measure employers and insurance carriers have begun to furnish their own medical service, establishing dispensaries and hospitals and engaging surgeons and trained nurses. Obviously a continued extension of the system of establishment hospitals and contract doctors would ultimately exclude a large majority of the medical profession from the field of industrial surgery. It is the evident extension of this practice that causes apprehension in the ranks of the profession and is the motive power behind their movement for free choice of physicians.

Contract Doctors and Establishment Hospitals

When state compensation laws were first enacted many of the larger employers had in operation benefit schemes for the protection of their employees in case of accident or sickness. The compensation laws in about one-half of the states permitted these substitute schemes to continue, provided the benefits furnished equaled those provided in the compensation acts. Thus, many, if not most, of the larger employers in the United States at present have their own organized medical service and establishments hospitals with surgeons and nurses in charge. This is especially true of the far western states where the system of establishment hospital and benefit funds prevails. In fact, the compensation laws of seven western states¹¹ specifically authorize employers to make contracts with their employees for medical and hospital service. Employees generally are required to contribute \$1 a month for the support of these funds and hospitals, but the medical service furnished usually covers sickness as well as accidents.

One criticism of the contract system is that the cost of the medical benefits under the compensation law, a burden it was intended for the employer to assume, is shifted to the employees. Another criticism is the commercialization of the medical service by non-medical men. In Washington, for example, the contract plan has given the state medical aid board considerable trouble because of such commercialization. These non-medical men form a hospital association and then secure the services of a surgeon, pay a small part of the proceeds to him for the work and keep the remainder. This has brought about a lot of dissatisfaction among the workmen and physicians

of the state and has caused some agitation toward state hospitals for the care of workmen under the compensation act.

The most potent criticism against contract practice is that through it injured employees receive inferior service. As already stated, many employers furnish medical and surgical treatment of the highest character, but that is not the general custom and is especially not true in case of many insurance companies. The California Industrial Accident Commission¹² in its 1916-17 annual report is unfavorable to the contract system.

Medical and Hospital Fees

Probably no one phase of workmen's compensation has created more administrative difficulties or caused more ill feeling than the question of medical and hospital fees.

Prior to the enactment of workmen's compensation laws there had been little distinction in the treatment of injuries which arose out of the employment and those which arose outside of the employment. In either case the person sustaining the injury was financially responsible for the medical and hospital treatment furnished; but since a large proportion of such persons were unable to pay for the treatment received the hospitals and physicians accepted them as charity patients, usually charging low rates and collecting fees only in cases where the patient could afford to pay. The compensation laws, however, definitely placed upon the employer the burden of furnishing medical services in industrial accident cases; but no provision was made as to medical fees, except that they should be reasonable, and, in sixteen states,¹³ that they should be limited to such charges as prevail in the same community for similar treatment of injured persons of a like standard of living when treatment is paid for by the injured persons. In view of these facts the medical profession as a whole maintained that medical services in industrial cases should be remunerated at full value and that such cut rates and charity as had been granted the sufferers by hospitals and doctors should be discontinued. They also believed it to be an injustice to expect the medical profession to adopt a sliding scale of fees, governed by their clients' ability to pay, when other institutions and businesses, including the very same employers and insurance companies, are not subjected to the same principles and practices.

Obviously, the medical profession, in common

¹¹ Colorado, Idaho, Montana, Nevada, New Mexico, Utah, and Washington.

¹³ Connecticut, Hawaii, Idaho, Indiana, Kentucky, Louisiana, Maryland, Minnesota, Missouri, Nevada, New York, Oklahoma, Tennessee, Texas, Vermont, and Virginia.

with other professions and vocations, should receive a just and adequate remuneration for its services. The ordinary fee rates of physicians are probably determined in a general way with reference to the paying ability of the moderately well-to-do classes of society. Undoubtedly they are also influenced by the fact that much of the medical service rendered the poorer classes will never be paid for. In view of these facts what would be a just basis for determining reasonable and equitable fees for medical services? As already stated, sixteen laws provide that the standards prevailing in the community for treatment of persons having the same standard of living should be taken into consideration. Three states¹⁴ further provide that the increased security of payment guaranteed by a workmen's compensation law should be taken into account. Practically all of the state commissions do consider these factors in determining the reasonableness of medical fees.

The ultimate determination of the reasonableness of medical fees in workmen's compensation cases lies with the administrative commissions and courts.

Medical Fee Schedules

In twenty-eight¹⁵ states the compensation commissions or courts are specifically authorized to approve, regulate, or fix the amount of medical and hospital fees. The laws of two states¹⁶ authorize the commission to issue a table or schedule of fees which shall serve as a basis for compensating medical services rendered. Moreover, medical fee schedules have been put into effect, under general authority to regulate or approve medical fees, by the compensation commissions of the following states: California, Maryland, Nevada, Ohio, Oregon, and West Virginia. Also, the Massachusetts and New York compensation commissions, in approving medical fees, have been governed by a medical and a hospital fee schedule formulated in cooperation with the medical profession, hospitals, and insurance companies of the state. In New York, however, the state medical society later repudiated the fee bill because the insurance companies interpreted it as "a maximum fee bill, not as a minimum fee bill."¹⁷

In addition to the foregoing official schedules promulgated by the state compensation commissions, medical fee schedules have been adopted quite extensively by insurance companies, by many county medical societies, and by a few state medical societies. There is a fundamental difference, however, between the schedules adopted by the medical societies and those adopted by the insurance companies. The former are generally minimum fee schedules, whereas the latter are

maximum schedules. Moreover, the medical societies have difficulty in maintaining strict adherence to their schedules on the part of the members of the profession; on the other hand, relatively few of the experienced physicians and surgeons will sign the schedules of the insurance companies.

How Fees Are Fixed

The rates contained in the fee schedules adopted by the several states enumerated above are somewhat lower than the regular rates of the profession. In many of the states the rates approved vary between different communities, depending upon the prevailing rates in the locality. In Massachusetts, for example, the guideposts by which the industrial accident board determined the reasonableness of fees were (1) the locality in which the doctor practises, (2) the nature of the complaint, (3) the ability of the man to pay, and (4) the standing of the practitioner in his profession.¹⁸ In Ohio,¹⁹ however, the amount of medical fees was determined with a view to impartiality and uniformity.

Because of the great variations in kind and amount of treatment required even for similar and apparently identical injuries, it is impossible to determine in advance what would be a reasonable fee for a particular injury. Consequently a medical fee schedule is commonly used merely as a guide or as a minimum fee table.

Because of the medical fee question, workmen's compensation laws have been the subject of a considerable objection and adverse criticism by a part of the medical profession. The large majority of the profession have cheerfully cooperated with the commissions in the administration of the laws in the interest of the working classes for whose benefit such laws were enacted, and it is seldom indeed that a compensation commission has had difficulty with the higher class physician and surgeon.

Many Angles to Fee Problem

The problem of determining the reasonableness of medical fees is further complicated when the injured man is sent to the hospital. The added difficulty arises from the fact that hospitals are in part charitable institutions and supported by donations of public spirited citizens. Hospitals

¹⁸ First annual report of Massachusetts Industrial Accident Board, 1912-13, p. 56.

¹⁹ Ohio Industrial Commission Bulletin, Oct. 1, 1914, pp. 14, 15.

usually have three classes of service,—public wards, semi-private rooms, and private rooms. The public wards are maintained at nominal prices, frequently less than actual cost, for patients who have limited means, which includes most of the industrial workers. Moreover, in case of public ward patients no charge is made for the attending physician or surgeon. For the other classes of service the rates are not only much higher, but fees for attending physicians and surgeons must be paid in addition. The question immediately arises, should injured employees be placed in public wards, as they probably would have been before the enactment of compensation laws, or should they be placed in semi-private or private rooms? If the former practice is followed the employers and insurance companies are benefited at the expense of the physicians and hospitals; whereas, if the latter plan is adopted, the remuneration received by the medical profession would not be in accord with the compensation acts, which provide that medical fees should "be limited to such charges as prevail in the same community for similar treatment of injured persons of a like standard of living when such treatment is paid for by the injured persons"; and consequently employers and insurance carriers would be required to pay more than was intended by the law. The insurance companies maintain that were the injured workman to pay for his own medical and hospital bills he would in most cases be sent to a public ward, and physicians would graduate their charges according to the patient's income and ability to pay.

On the other hand, the hospitals maintain that they should not be asked to treat compensation cases at a loss. The practice among hospitals varies. Some place compensation cases in public wards, some in semi-private rooms, and others maintain a "compensation ward" at intermediate rates. The practice of doctors in sending patients to hospitals also varies. The majority, however, recommend that patients be placed in semi-private wards, thus entitling them, according to the rules of the profession, to charge for their services in hospital cases.

However, it is the consensus of compensation commissions and many physicians who have investigated the matter that workmen's compensation laws have increased rather than diminished the income of the medical profession, and this despite the fact that the rates in industrial accident cases have been somewhat reduced. Certainly the effect has not been detrimental in a pecuniary way since the lower schedule of fees has been largely counterbalanced by the certainty of payments.

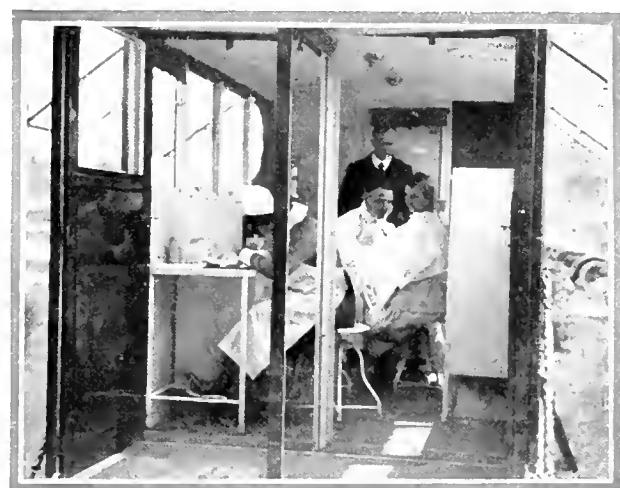

A TRAVELING TUBERCULOSIS CLINIC

At the conventions of the health organization and welfare societies in Chicago this year there has been exhibited a large, attractive motor-hospital which travels to

This traveling hospital goes to the patient, if the patient is too ill to come to the hospital. (Photo by International Film Service Co., Inc.)

all parts of the city. It is operated by the Chicago Tuberculosis Hospital and is sent to any place where a case of tuberculosis is reported, whenever it seems more desirable to visit the patient at his home. The automobile-hospital

The motor-hospital is operated by Chicago's Tuberculosis Institute is sent to any place in Cook County where it is desired to hold a clinic. It carries two nurses and a physician who co-operates with the physician in the communities visited. (Photo by International Film Service, Inc.)

carries two nurses and a physician. They may be called for consultation by a resident physician wherever visits are made with the traveling clinic.

Special Schools for Handicapped

The legislative measure introduced in the last session of the Pennsylvania Legislature covering the matter of special school training and special classes for tuberculous children and children having defects of sight or hearing, as proposed by Dr. Thomas E. Finegan, superintendent of public instruction, has been adopted by the assembly and has received the signature of Governor Sproul. The act was drawn up by the Public Charities Association. It provides for special training for incorrigible children as well as the physically handicapped. Clinics for medical and mental examinations are authorized.

HOW INDUSTRIAL MEDICINE IS EXTENDED THROUGH MUTUAL BENEFIT ASSOCIATIONS

BY CHARLES H. LEMON, M.D., F.A.C.S., CHIEF SURGEON, MILWAUKEE ELECTRIC RAILWAY & LIGHT COMPANY,
MILWAUKEE, WIS.

THOSE of us who have specialized in industrial medicine and surgery have learned that the care of the health of large groups of workmen is a very different matter from the ordinary practice of medicine in which the family is the unit. If the relation between the physician and family for any reason becomes unsatisfactory to either of the parties, the relation is easily terminated and, except for some neighborhood gossip, the matter is soon forgotten; another physician is employed; another patient comes to the doctor, and the former relation is perfectly balanced without prejudice to either. With a group to deal with, however, the situation between the patient and doctor is not taken care of so easily. We are dealing with the individual or the family it is true; but the individual and the family have a corporate relationship; and the moment this situation occurs, the entire group becomes an interested party. This phase of our work is soon impressed upon us, because we must deal with the man higher up; and sometimes, the man higher up is the general manager, who is personally interested in the welfare of each of his employees without distinction as to the class of employment.

Wise Selection of Physicians

In selecting men for association physicians, care is therefore necessary that none be employed except those who have first had a good technical education; which would imply a proper hospital internship; and second, those who are willing to work and who are what is popularly known as good mixers.

The amount of compensation that a mutual benefit organization can pay for medical services has definite limits. I do not mean by this that the doctors should be underpaid, or that cheap, inefficient service should be accepted. In order to

THE PHYSICIAN AND THE GROUP

Preventive medicine finds its highest application in the group form of service.

The individual physician cannot possibly care for as large numbers in serving a miscellaneous population as in the care of a group. By reason of this the mutual benefit association is enabled also to pay the physician a larger fee in the aggregate.

With the cooperation of employees, both individually and through their representatives, the directors of the association, there is opened an opportunity for the conservation of health such as is presented to few groups throughout the country.

obtain the maximum efficiency, the mutual benefit association must be subsidized by the employing corporation, in the matter of furnishing without cost to the association a surgeon's services, the surgeon acting as medical director and performing the necessary ordinary surgical operations for the Employees' Mutual Benefit Association as a part of his usual duties as chief surgeon for the corporation. Fortunately for the

groups represented, surgeons are employed by the operating companies whose services are given by the company to the Mutual Benefit Association, gratuitously. By this method a supervising medical director is provided, and the medical service furnished is limited in its excellence only by the character, experience, and professional standing of the chief surgeon of the operating company.

Attitude of Employee-Patients

That the service of the physicians is exacting is well known to the physicians themselves. The man calling for a doctor is interested only in his own requirements and it is our experience that he frequently is less considerate in waiting for an association physician than he would be if he were calling for a private doctor. This, however, is not frequently the case, as the large body of our membership in the Association is composed of men and women who are reasonable and intelligent.

It has been the experience in Milwaukee that a central office is essential for the handling of any large group of employees. At the general offices at the Public Service Building all are welcome without reference to the districts in which they may reside. It is noted with interest that an increasingly larger number year by year come to the general office for consultation even while under the care of the local physicians. A large

*Read before joint conference of chapters of Milwaukee Electric Railway and Light Company's Employees' Mutual Benefit Association, Milwaukee, Wis., March, 1919.

number also, year by year, are being referred to the general office by the association physicians in the surrounding districts outside of Milwaukee, because they can avail themselves of the larger experience as well as of the various clinical means of diagnosis which are not available elsewhere.

The public generally is being educated to the larger use of the x-ray as a means of diagnosis. They are becoming equally insistent, and properly so, in the demands for more careful laboratory investigation of their ailments. These facilities should be provided by the various associations, if they are not already so provided. This is an age of specialties and a successful physician in the service of an employees' mutual benefit association must be a good all around man. When he is unable to make a diagnosis, it is his business to refer the case to his superior or bring the case to the general office for consultation, or invite the chief surgeon or his assistant to see the case in consultation at the patient's house if he is unable to go out.

Personal Element in Group Practice

It is team-work such as this which is absolutely essential to the successful operation of any group plan of medical service. I feel that this service should be made so excellent that it can successfully compete with any private service in a locality where large groups of men are being employed. If the members are impressed by the fact that they are being given the very best service that can be given them in their locality, they are bound to be satisfied. If this service is the best that can be had, results will be obtained and will be shown in saving of "day's disability" as well as in the saving of life itself. It is the early, correct diagnosis followed by appropriate treatment that turns the trick as far as we are concerned. The man who is a good mixer alone with a bold front, will not last long among a discriminating group of employees, such as are found in our large public utilities. He must have a scientific mind as well as a trained mind if he is to succeed. All the pleasant remarks in the world will not compensate anybody for the death of a child treated upon a wrong diagnosis; and a man with an acute appendicitis will not later look with favor upon the doctor who treated him for acute indigestion.

Personal Relationships in the Group

It should be the aim of the association physicians to render the best service they are capable of; to do it cheerfully and promptly. At the same time it becomes the duty of the association members to give the doctors the benefit of the doubt,

if they are delayed in answering their calls, and at all times to regard the doctors as their friends who are interested solely in their welfare.

There is a growing opposition in this country to social insurance on the part of the medical profession. This opposition is based on fear rather than on facts; because the profession sees in the group medical service the surrender of certain privileges that they have ever regarded as personal and as prerogatives. My experience based on seven years of observation of the working of this group medical service, is that with the lapse of time, each physician makes more and more friends among the membership of his own particular group, and that there is really no difference in the personal relationship of an association physician to his patient, as a member of a group, than there would be if he were a private doctor employed from time to time by an individual.

From the standpoint of health, the group plan has many advantages. A service which can be had for the asking will be used effectively. Men are curious to know what ails them, and this curiosity can be satisfied if no extra expense is incurred in the investigation. And why should not this be so? If medicine is of any use whatsoever, its greatest usefulness should be the seeking out of blind disorders and remedying them, before they have become dangerous factors in a man's life. Preventive medicine, therefore, finds its highest application in the group form of medical service. Experience has shown that a man with a cold, or a headache, or a beginning rheumatism in the joints, or with some other equally slight ailment, is not going three or four miles to consult a doctor. If at the place of his employment a doctor is available at a given time during the day, experience here has shown that he will consult the doctor. Any intelligent physician knows the meaning of these early signs of sickness and he can and will administer appropriate remedies or give suitable advice, which will check the disease in its beginning.

Reduce Time-Loss from Disability

In Milwaukee in 1916, by this intensive medical service, the day's disability among our trainmen was reduced to four and a half days per man per year. During the recent epidemics of the Spanish influenza the situation could not have been handled by our medical force, if centralized medical service were not to be obtained.

There is a physician present in every car-station and in our car-shops for a period varying from thirty minutes to an hour and a half every day, except Sundays and holidays. In addition at the surgeon's office in the Public Service Build-

ing, patients are seen from 11 to 12:30 o'clock in the morning and from 3 to 5 o'clock in the afternoon. No request has ever come to us from the employees to alter this plan. I, therefore, assume that it is both acceptable and helpful.

In considering "Why and How to Keep Well," I might quote you the words of Dr. B. S. Warren, Assistant Surgeon General, United States Public Health Service, in a recent bulletin.¹

In these days of progress in preventive medicine there is some tendency to separate too sharply the preventive from curative medicine. It should not be forgotten that an adequate medical service to the whole people will do more to prevent disease and disability than any other single measure to be considered. At present the people in the United States are paying out money sufficient for the maintenance of an adequate medical service, but fail to receive it. This money, however, is spent in such a haphazard manner that the service is not only often inadequate or worthless, but at times actually harmful. For one item—drugs—the United States spends \$500,000,000 a year. This sum alone, if properly expended, would buy all necessary drugs and add \$2,000 a year to the income of each of the 125,000 physicians in active practice in the United States. It may be safely stated that an adequate medical service cannot be had except in our medical centers, and in these centers only the rich and some of the charity patients receive such service. The great middle class cannot afford such expense. Since the people as a whole are paying the price for the best, there should be no reason why they should not have the best. With a proper organization, distribution, and training of the medical and sanitary personnel of the country, and a proper expenditure of the funds now being spent for medical purposes, there would be available, to every person, adequate medical and hospital services and supplies. With such service closely coordinated with, or forming part of, the health department, it needs no argument to show that disease prevention would begin at the source—the bedside, and eliminate a large proportion of disease.

"Industrial hygiene is another subject which must be given careful consideration in working out a unified health-service program. All labor departments are vitally concerned in this subject. The War Labor Board announced as one of the principles governing its awards, a living wage sufficient to maintain a family in health and comfort. With such a recognition of the importance of health it then becomes the duty of the health departments to work out the standards of health in industry and to cooperate with the labor departments in their enforcement. In this group of the population, as in school children, it should be clearly recognized that the health departments are responsible for the health of all the people and that the industrial workers are no exception."

In the city of Milwaukee we have an excellent health department, directed by an unusually competent health officer. The company at all times has cooperated with the health department, not only in matters concerning the health of our employees, but in conserving the health of the patrons who ride upon the company's cars. Perhaps the most important conferences held by the health department in the recent epidemic of the Spanish influenza were those held with the com-

pany's general manager, S. B. Way. The cars were disinfected; notices to prevent crowding were freely used; ventilators were blocked open so that those who were not cooperating could not close them. All social activities were abandoned, and preventive measures, such as the use of antiseptic powders, were employed. The company believes these measures had much to do not only with conserving the health of its own employees on the cars, but in helping to conserve the health of the patrons who rode on the cars. It is my observation, that a large percentage of people, among whom are many physicians, are indifferent to any measures to preserve their health. The doctor with the pulmonary tuberculosis is the last one to sleep in a tent or even keep his window open at night. An individual who believes in personal rights to the exclusion of all others rights is the man or woman who insists on boarding an already full car, when one more than one-half empty is less than half a block away.

Preventive Measures Made Effective

The Employees' Mutual Benefit Association has been a pioneer in Wisconsin in the matter of health conservation, by treating men in groups, and not only treating them, but taking other preventive measures for the health.

The rich can afford the best service there is and the poor man can get the same service in the well organized hospital clinics. It is the middle class, the shop worker and the industrial worker, who are unable to get either; and it is mediocre medical service which has filled the graveyards and the institutions for the treatment of tuberculosis.

An intelligent, well trained medical man who is directing the health supervision of a large group of industrial workers, will foresee the early symptoms which lead to organic disease and, by well considered advice, will prevent workmen from succumbing to it.

A well organized health department in a large city is the best investment the city can make. In Milwaukee the city fathers have been generous in support of the health department. It supervises many agencies, which are coordinated with our work. And I cannot speak too highly of our Wisconsin Anti-Tuberculosis Association with its magnificent sanatorium, known as Muirdale. Without charge to employees and with a willing cooperation that is worthy of the highest commendation, they have assisted in the diagnosis of incipient cases of pulmonary tuberculosis and there have been many instances of employees who

have been restored to health through the treatment there given.

It must be recognized that these agencies for health preservation are highly specialized and it is only by a thorough cooperation with such agencies, both in our industrial and public relationship, that the best results can be obtained. It is not a mere accident that the incidence of pneumonia and the Spanish influenza was so low in Milwaukee in the various epidemics. A close personal acquaintance with the head of the health department will convince anyone that preventive measures are followed by definite results. I am speaking to you of Milwaukee, because I am familiar with the local situation here. With the same attention to detail, with the same care in the selection of association physicians, with the same generosity on the part of the manager in providing proper places where men can be treated in groups elsewhere than here, the same results should be attained.

Health and Climate

The climate in Wisconsin is more rugged than elsewhere on account of contact with the great lakes. We have to caution our men about the use of woolen underwear; because with the change of the winds, a perfectly warm day in summer, may take on all the characteristics of Fall weather in less than an hour. I know of no better protection against these changes than the systematic use of the woolen belt. In the Russian-Japanese War, every Japanese soldier was equipped with one of these belts and, by their use in conjunction with the use of boiled water, diarrheal diseases, so common to military camps, were prevented.

An advantage over ordinary and industrial groups may be claimed for the association in that everyone that comes to work, comes as a selected risk. The company endeavors by a preliminary examination to eliminate the derelicts from the organization. With the increase in pay which streetcar employees have been given during the past year, they have acquired a living wage, sufficient to maintain their families in health and comfort. The home hygiene should, therefore, be very greatly raised and with this improvement there must come a corresponding improvement in the general health.

Compensation for Association Doctor

I am convinced that with a miscellaneous population it would be impossible for physicians to care for as large groups as are cared for in our various associations. This enables us to pay a larger fee in the aggregate to our association physician than would be possible in a mixed popula-

tion, not less than 20 per cent of whom would be found below a normal standard.

It is my privilege as the director of the parent association to address these thoughts to you today. We feel that we are pioneers in this great work and we are also persuaded that in undertaking it, we have the support of the greatest organized governmental agencies from the Public Health Service down. We have endeavored at all times to cooperate with these agencies to the fullest extent. Representatives from the various Governmental boards have investigated our work and we have listened to suggestions for its betterment. We realize that with the cooperation of the employees, both individually and through their official representatives, the directors of the association, we have an opportunity for the conservation of health such as is presented to few groups throughout the country.

To Mr. James D. Mortimer, to whom conception of this great plan is due, as well as his earnest support of this congress of the various allied associations, all are under the deepest obligation. We have no excuses to make for our work and no apologies to offer. Its record is open to investigation by all and as the director of the parent organization I can only say we are proud of that record.

CONFERENCE TO DISCUSS HOW MEDICAL SERVICE CAN BE IMPROVED

The medical session of the sixth annual meeting of the International Association of Industrial Accident Board and Commissions, to be held at Toronto, Can., September 23 to 26, will be devoted to a discussion of the subject, "How Can Medical Service Be Improved?"

Dr. F. D. Donoghue, medical adviser to the Massachusetts Industrial Board, will sit as chairman of the morning session. Dr. F. H. Thompson, medical director, Oregon State Industrial Accident Commission, will be chairman at the afternoon meeting.

Those participating in the discussion will be Drs. Donoghue J. W. Trask, chief medical director, United States Employees' Compensation Commission; Dr. Otto P. Geier, director of the employees' service department, Cincinnati Milling Machine Company, and Dr. M. R. Gibbons, medical director of the California Industrial Accident Commission, who will prepare a paper, though possibly will not attend.

The following speakers and subjects are announced in a tentative program for the medical session: "Disabilities as Aggravated by Pre-existing Conditions," Dr. P. B. Magnuson; discussion by Dr. J. W. Mowell, chairman of the Medical Aid Board of the state of Washington, and W. E. Struthers, M.D., chief medical officer, Workmen's Compensation Board of Ontario; "Infections of the Upper Extremities," Dr. P. A. Bendixen, Iowa; "Cancer, With Special Reference to Sarcoma in Its Relationship to Trauma," Dr. Raphael Lewy, chief medical examiner, New York Bureau of Workmen's Compensation; discussion by Dr. P. A. Bendixen, of Iowa. "Eye Injuries," Dr. F. C. Thebilcock, of Toronto.

THE SURGEON IN RELATION TO PUBLIC UTILITIES

BY CHARLES M. HARPSTER, PH.G., M.D., F.A.C.S., TOLEDO, OHIO; CONSULTING CHIEF SURGEON FOR OHIO, HENRY L. DOHERTY COMPANY, NEW YORK CITY

Part II

IN reviewing large numbers of cases in different types of trauma, it is intensely interesting to note the many problems presented. In the many claims against a traction company for injury it is for the surgeon to determine the exact degree of injury, in fairness to the company and without prejudice to the patient; to separate the just claim from those in which rank imposition is planned; to differentiate the psychic from the physical factors; to find means for the most rapid and the most complete possible restoration of the injured. This is no small task, but the statistical

Two views of fixtures and plumbing installation at the first-aid station of the Acme power plant.

study of all records of the medical staff of the Toledo Railways & Light Company has resulted in the fixing of certain standards and interpretations which are interesting in themselves and are published to draw out information as to the accepted procedures of other similar departments.

Head Injuries

In a recent study of 7,500 cases of trauma, based upon all cases treated covering a period of less than five years, it was found that a little less than 2.5 per cent were head injuries, simple scalp wounds not being included in this category. Many of these cases required to be seen but once. From this experience the department has adopted for the handling of cases of fracture at the base of the skull the rules laid down by Bunts:¹

(1) Simple cases of fracture of the base of the skull without severe laceration of the brain; practically all get well without operative interference.

(2) The greatest cause of danger in these cases is from septic meningitis and operation cannot prevent this complication, but rather adds to its probability.

(3) The bad cases, complicated by a bursting fracture of the skull with an extensive laceration of the brain; practically all die.

(4) It is in this class of cases that operations, such as removing spicula of bones, crushed brain, etc., are most frequently resorted to, but usually without avail.

(5) Distinct compression systems coming on immediately after the injury without obvious evidence of extensive brain laceration would probably be deserving of decompression operation, for they might be due to hemorrhage or edema, and should be subjected to immediate operation.

(6) There are insufficient available statistics as yet to show that decompression operations hasten the recovery after fracture of the base, or lessen subsequent liability to cerebral disturbances.

Fracture of the Skull

It is to be noted that in the one case in which Bunts had an opportunity to try out the plan under his fifth postulate operation and subsequent necropsy showed no clot, very slight hemorrhage, but extensive laceration of the brain, not only in the lowest frontal convolution near the site of the fracture, but in the occipital region, far from the fracture, the laceration of the brain was even greater than in the frontal region.

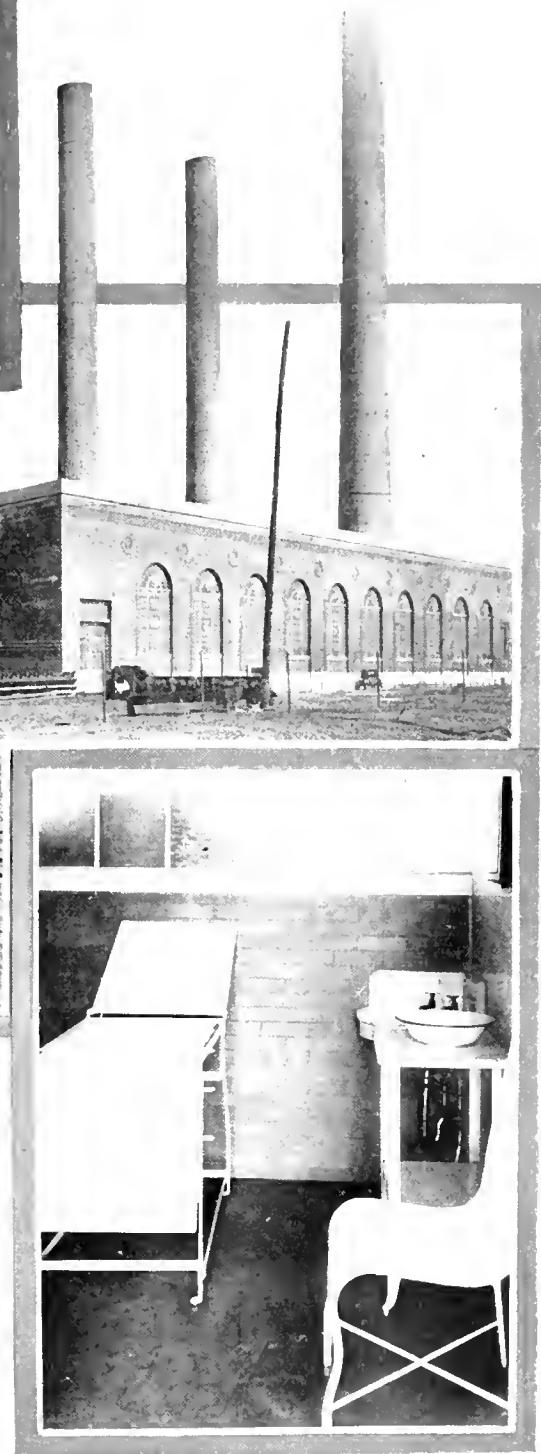

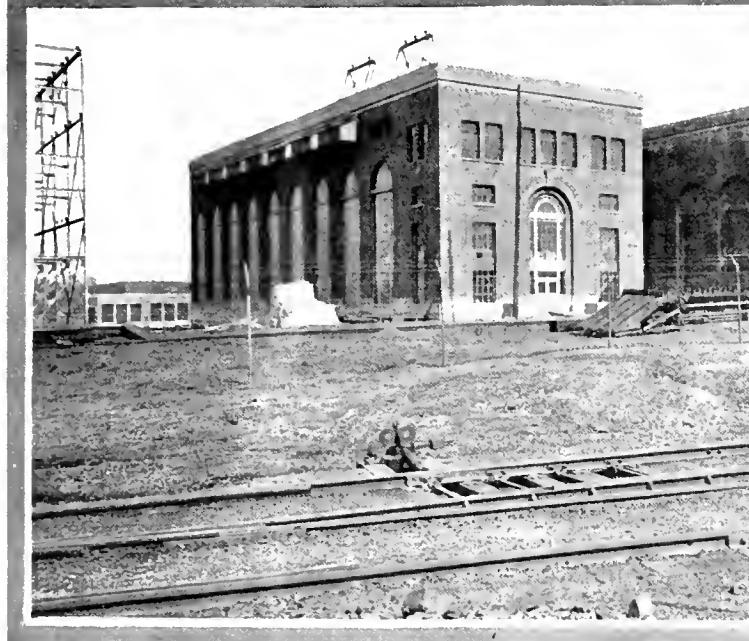

There can be no satisfactory classification of intracranial injuries but it is certain that these injuries should not be regarded purely from the standpoint of fracture of the skull. The x-ray will reveal fractures of the skull in many cases not diagnosed by the clinical findings. The least important condition in injuries of the cranium is the fracture of the skull itself. A patient may get up and walk away after an injury to the head and in some instances may resume ordinary duties and then grow progressively or very rapidly worse, and die.

Subtemporal decompression is greatly advantageous in some cases. The skull is a closed box, the brain cannot expand, and, unless the pressure is relieved, there ensue anemia of the vital centers and death. Decompression gives relief from the pressure by drainage of the cerebrospinal fluid and extravasated blood. It should be employed in selected cases. In cases of basal frac-

¹Bunts, F. E.: Diagnosis and Prognosis in Fractures of the Base of the Skull. Arch. Diagnosis, N. Y., 1917, x, 196-202.

The industrial nurse has taken a place in the modern world of industry beside the industrial surgeon and physician which, by the character of service she performs, secures ever increasing recognition and appreciation from men and employers.

A monument of industry, and one of the members of the personnel that makes up the operating force of this Twentieth Century power station. The power plant is the first unit of the Acme Power Company, Toledo, Ohio. In the smaller building there is an emergency hospital and first-aid station. The upper photograph shows first-aid station and an attendant, a typical portrayal of the modern ideal of medical service for the workers of industry. The lower photograph shows a well-equipped dressing room in the Acme first-aid station. Every public service company of the Doherty system has similar facilities for the maintenance of man power in the plant and in the office.

ture, with free discharge of blood, etc., from ears, nostrils, and mouth, operation *per se* is not indicated. The most vital point in this procedure is that decompression should be done soon after the injury is sustained; the earlier it is done, the better the prognosis.

In this connection it may be well to note that

lacerations of the scalp are often improperly diagnosed, by parties interested, as fractured skull. These cases of supposed fracture are not included in the percentage given of skull injury. Many cases said to be depressed fractured skulls, without any real clinical symptoms, are seen, the diagnosis being based on the subjective symptoms

and on the finding of a natural depression in the skull. Such findings may be well bolstered up by x-ray plates, taken at angles to show best an apparent fracture. In the presence of a depressed fracture of the skull of any consequence, usually the patient is profoundly injured and the clinical symptoms constitute a sufficient guide for diagnosis if they are honestly searched out and understood.

The records of this company report the case of a man who was struck by a car. Notwithstanding the fact that he showed no clinical symptoms whatever, diagnosis of fractured skull was made by parties interested and a trephine operation started. Another case is typical:

Mrs. W., struck by car in April, 1917. She sustained a scalp wound one and one-half inches long on the posterior part of the right side of the head. A very careful and conscientious examination of the skull through the wound was made by one of the assistant surgeons but revealed no depression or any other evidence of skull fracture. Reexamination by the chief surgeon the following day disclosed no clinical symptoms of any moment. The second day following injury, the patient was removed from the hospital by her friends and attorney, and her physician at once found a "large depression of the skull." The fracture was demonstrated by three x-ray plates to the satisfaction of all parties concerned and immediate trephine operation was advised.

An adjustment of her claim was asked for and the case came again under the attention of the medical department. The chief surgeon thoroughly reviewed all findings and gave as his opinion the statement that a fracture did not exist. Two of the plates showed what a strong imagination might construe as a fracture, but these plates were taken at cross fire and the supposed point of supposed fracture was at different places on the two plates. The third plate did not show anything, not even a suspicious point. He advised that operation was unwarranted and that, in view of the indefiniteness of the plate and the absence of clinical symptoms, other plates should be taken. This was done and further plates by other operators were negative. The claim was adjusted and, at last reports, the patient's skull had not been trephined.

The possibility of mistaken diagnosis should always be considered—and the physician should ever be alert for new findings, and open for the re-construction of a case if new data can be obtained. Perhaps the most baffling and troublesome decisions to handle are those in connection with so-called traumatic neurasthenia.

The injury cases of this company have involved the care of many thousands of cases of trauma following accidents on electric railways and allied industries. The conditions, real and assumed,

PHYSICIAN

Date Received by Claim Department

This discharge should be given by Physician to employee, who must at once report to Claim Department and deliver same.

Supplementing the form used by the Doherty physicians for notifying the claim department of the progress of a case, this form is used to inform that department when the patient's recovery is complete.

In a large majority of these cases the money to be received for damages seems to outweigh every other consideration on the part of the patient, his relatives, and his lawyers. A case in point is shown by the remarkable fact that in a certain settlement of our city, practically every married woman between the ages of fifteen and seventy who has been in a streetcar accident has had a miscarriage following such accident.

A few of the conditions that are usually attributed to an accident on transportation lines are enumerated: neurasthenia; goiter; varicose veins; floating kidneys, spleens, and livers; hydrocele; uterine fibroids; pus tubes; prolapsed and floating wombs; spinal curvatures; varicocele; rheumatism; and tuberculosis of the lungs and kidneys. Many other conditions too numerous to mention are a matter of record. As an example of what public service corporations have to contend with: a woman accidentally shot her husband in the head, and he was dead when the chief surgeon reached the hospital. She filed a claim for damage for his death. She had killed him while he was at work and, according to her reasoning, she was entitled to compensation for his death.

Floating Kidney

It is not only real or imaginary injury for which claim is made. It is only too common that physical defects are tolerated with equanimity, or may even be unsuspected, until examination after an injury brings to light the inherent defect which is either a predisposing cause for a real injury, the basis of an unjust claim that the defect was caused by the accident, or sufficient grounds

for the play of the fears of the disturbed psyche.

Perhaps the most frequently involved organ in this category and one that calls for discriminating decision, is the floating kidney. In spite of the fact that Guiteras and other reputable surgeons state that they have never seen floating kidney or other floating abdominal organs due to trauma *per se*, numerous claims are made for such conditions.

The records of this company show only one case of floating kidney thought to be due to

trauma. This was in a young man who fell into a pit, striking on his side on a board or scantling. Extreme prostration followed and considerable blood appeared in the urine. He was profoundly sick at the hospital for weeks. Several weeks following the accident his right kidney was found freely movable. He was given accident credit for the condition. Guiteras² says:

I feel that the claim that sudden traumatism causes movable kidney—such as a blow in the loins, a fall upon the knees, buttocks, or perineum, a blow on the thorax, a sudden muscular strain due to abrupt stopping of a car, and other claims of similar nature which are used in suing corporations and railway companies is groundless.

In all such cases if the traumatism had been sufficient to displace the kidneys suddenly, it would give rise to a dangerous hemorrhage, perhaps sudden death.

It is really the traumatism of mild character that causes the trouble, as has . . . been mentioned under corset and belt pressure. I believe that persons who suddenly complain of pain in the loin after a shock, a car accident, or jar, and in whom a movable kidney is found on examination, would have shown the presence of such a condition had they been examined before the accident; but as there was no reason for such an examination, the presence of a movable kidney was not known. On the other hand, when a movable kidney exists, a sudden jar or wrench may give rise to renal strangulation, and thus bring on symptoms that might induce one to believe the mobility has been caused by the recent traumatism.

Goiter is another condition claimed to result from injury. Drysdale³ reports cases of alleged

an exophthalmic goiter cannot occur. In other words, there must be an inherent predisposition to the malady. It is also my opinion that the degree of physical violence has little, if any, significance and whatever harm is done in this respect arises from shock and emotional storms acting through an unstable nervous and psychic constitution. Trauma, therefore, becomes only a determining factor.

The form in use by the Doherty medical departments for reports of blood examinations. In the various affiliated corporations, the different forms are adapted to local requirements, but are identical in most particulars.

This, I think, will adequately explain why so few cases develop following physical violence, and why so many of the ordinary cases arise from influences which are in no manner related to traumatism.

No case of goiter that by any gymnastics of the mind could be traced to trauma is recorded by the Rail-Light Company.

Traumatic Neurasthenia

This nightmare is comparable to that ancient monstrosity that Erichson¹ dubbed the "railway spine." The term neurasthenia has made fortunes for numerous members of the legal profession. The prognosis of "legal neurosis" or the "litigation neurosis" of Miller² often varies inversely from the time of settlement of the individual's claim for damages. Many cases recover spontaneously as soon as the money for damages has been paid over. In hundreds of cases of so-called traumatic neurasthenia none of the persons traced failed eventually to resume his ordinary vocation after a satisfactory settlement of the claim.

After a complete revision of the symptoms of hysteria and neurasthenia, Babinski³ showed that most of the symptoms are due to medical, legal, or other suggestion. Society people willingly and cheerfully dub themselves neurasthenic although wealthy society ladies never have the traumatic form of the condition. The term is also employed to cover diseases the patient is not anxious to make public, such as certain psychopathies. Doctors themselves have contributed in no small measure to popularize the condition and the use of this term by the public. As Dejerine⁴ and Gauckler remark, physicians tax their patients with neurasthenia and then tell them that their troubles are nervous.

Beard⁵ and Charcot imagined that they were describing a definite disease. As a matter of fact, the malady is characterized by well marked symptoms. Neurasthenic headache, digestive disturbances, rachialgia, amyostenia, insomnia, etc., constitute the most distinctive features. Along with these are found many secondary symptoms. A distinct, morbid entity could be extracted from this group of manifestations. The majority of the symptoms are emotive phenomena. Even neurasthenia itself tends to become blurred and, according to Beard and Charcot, out of 300 patients examined and declared to be neurasthenic, not one presented the signs formerly attributed to this neurosis.

In the neurasthenic subject fatigue, depression, fatigability are characteristic, but these are wholly inadequate of themselves to create a morbid entity which, moreover, possesses no anatomical features of its own. Almost nothing specific is found in the etiological conditions nor is it possible under the condition to give any pathologic definition.

⁵ Beard and Charcot: *Le Monde méd.*, 1917.

According to Dejerine neurasthenia is little more or less than a polyvalent syndrome. As a rule, when the doctor says neurasthenia he has in mind certain unexplained but not necessarily inexplicable troubles. It often happens, indeed, that on following up the study of the neurasthenic symptoms they are found to be connected with some morbid process in evolution, or to a lesion of some kind. Professor Legueu^a recently showed this to be the case in respect to certain ill defined urinary disturbances described as neuropathic or neurasthenic. If, given a case of neurasthenia, each manifestation is taken separately and its etiology and development investigated, each symptom is referable to one special pathological process not strictly speaking in the domain of neurasthenia. Dejerine and his pupil, Gauckler, have endeavored to define exactly the origin of the disease in the 300 persons they describe as neurasthenic; 103 were originally mental subjects; 121 were organic, and in 76 the affection supervened under the influence of emotive states. Suggestion is a common source of neurasthenia. The majority of their cases (121) were dependent upon ill-defined organic affections; for instance, in 3 per cent of these patients thyroid troubles were at the root of the neurasthenia. In others malaria had been at work, or grave enteritis, tuberculosis, arteriosclerosis, etc.

A goodly group was made up of debilitated subjects, the psychically unadapted, as Dejerine calls them. These subjects are healthy and their organs are intact, but they lack physical energy and break down on the least exertion. Closely allied to this category are patients who are, so to speak, wound up for some trifling task, but they are unable to stand their ground directly they are subjected to a little extra strain. The fatigue which they experience is, in them, a factor in the production of neurasthenia.

An organic affection, even if trifling and devoid of pathologic significance, will set up in the neurasthenic violent local reactions radiating out of all proportion to the producing cause. Similar lesions are not equally well borne by subjects of healthy constitution and neuropathic temperament. For instance, two patients may be suffering in the same degree from asthenia and extreme depression and may be unable to walk. One has cancer of the liver, the other merely floating kidney. A young woman suffers from intense neurasthenia with pain in the region of the heart, but careful examination reveals in her a periostitis of the fifth rib.

Emotional causes are often at the root of these

neurasthenic disturbances. It is more the duration of the emotional trouble than its intensity that weighs in determining the genesis of morbid phenomena. These patients might be labelled "moral unadaptables," they display such a disproportion between their mode of life and their constitutional aptitudes.

No one would venture to advocate that these various categories can be included in the same morbid group, and neurasthenia must be regarded in a very different manner. It may possibly retain its place in neurology, but its field must be limited and certain eliminations must be established. To begin with, all asthenics are not neurasthenics. Those who present troubles of thyroid or suprarenal origin are only accidental neurasthenics. Hepatic subjects must also be eliminated as well as the debilitated, and those suffering from melancholia, hypochondria, or psychasthenia.

Speaking generally, emotion is accorded a much too modest influence in works on pathology, yet it is universally admitted that emotions may cause functional disturbances throughout the economy. The functions of nutrition are under the immediate control of the functions of relation, and those are comprised in the much more general function of adaptation and this is disturbed by the emotions in a more or less durable or fugitive manner.

The neurasthenic state is nothing more than the totality of the constitutional or particular disturbances resulting from the emotional state acting on a given soil, and the various mechanisms by which a patient is rendered neurasthenic act as simple emotional causes. The inability to adjust the mechanism to an intense emotion, whatever the cause, represents an intrinsic inferiority and the consequent symptoms of depression, fatigue, and exhaustion may be summed up as neurasthenia. Mental, organic, or emotional causes may induce the condition, the last named preponderating. That all organic causes do not have this result is due to the fact that they often occur in ill adapted subjects and manifest themselves only on definite neuropathic soils. Our conception of neurasthenia should be limited to the totality of the disturbances which arise from the permanent action of emotional states.

From the records of this company one case may be cited to show how the condition may be abused:

A woman, 38 years of age, of emotional nature and disposition accidentally fell from the step of a motionless street car. She was immediately taken to the hospital where thorough examination failed to reveal any signs of physical or organic lesion. She threw herself into muscular contractions and fits. There was anesthesia of the skin in places, hyperesthesia in others, and there were

^a Legueu, Félix: *Le Rien Mobile*. J. B. Baillière et fils, Paris, 1906

functional disturbances too numerous to mention. Left after several days, dissatisfied with the treatment received in the hospital, with her nurse, her bed, her diet, her physician. Went to bed at home and on the suggestion of friends and lawyers stayed there for months. Trial of her case defeated her claims. No appeal was made. Immediate recovery followed, the case being one of hysterical and emotional neurosis—neurasthenia, if you please—with the gold-releasing word, traumatic, superimposed.

A rather interesting observation in this connection may be cited in the fact that 99 per cent of shell-shocked American soldiers have recovered.¹⁰ "There is less insanity in the American army than in any of the other allied armies," says Colonel Salmon. This recovery of so high a percentage of men from shell shock, Colonel Salmon attributes to the high standard of physical examination required for all soldiers going abroad.

INDUSTRIAL MEDICAL SERVICE*

The diverse influence exercised upon the health of the adult community by industrial environment is a matter calling for immediate action. The facts are so well known that attention need only be drawn to the much heavier mortality experienced by males in industrial districts than by females; while in country districts the mortality experienced by the two classes is only moderately against the male. The present organization of public health work makes no attack on this serious state of affairs; concerned as it has been, and is, with such things as water supply, insanitary dwellings, sewage disposal, and food supply—all matters of undoubted importance to which the health of the community has reacted—it has not established personal touch with the individual. In this respect preventive medicine has differed from curative medicine, which brings the practitioner into close contact with his patient. The result has been that with regard to preventive medicine the public has cared for none of these things; and advance must be slow until the public does care and appreciates that the health of each individual is not merely a personal matter, but one which acts upon, and reacts to, the health of the community. This will not occur until the profession establishes personal touch on health matters with the individual. Recent developments are, however, tending thitherwards: maternity and child welfare centers now deal directly with mother and infant, and the school medical officer deals with the individual child. Still, the personal well being of the adult is left uncared for. How is the profession to establish contact? One way has been pointed out by Dr. H. G. P. Castellain in a recent letter to the *Times* (London), advocating the employment of trained industrial medical men as full-time or part-time salaried officers in factories. The gathering together of workers in industrial establishments forms groups of persons exposed to similar risks and to similar environment which may be unfavorable. Here their health can be supervised from the moment of engagement throughout industrial life as readily as that of children in a school. Personal contact can be established just where it is most likely to be valued by improving the conditions of labor and easing the toil of daily life; and influence can be directed upon what is recognized to be the darkest spot in the health of the community,

and upon the environment that renders it so dark. Dr. Castellain sets out at some length the multifarious duties which a factory medical officer should undertake, and rightly concludes that there are but few medical men capable of discharging them. He then puts forward the proposal that a Diploma of Industrial Medicine should be instituted as distinct from a Diploma of Public Health. The field of preventive medicine is certainly wide enough to-day to justify action on these lines, but unless a demand is created on the one side and a supply to meet it on the other it will continue to exist unmet. A policy of delay to see whether some government department will some day do something does not recommend itself to us. The Association of Certifying Factory Surgeons should take the matter up with the new trades councils on the one hand, point out to them the advantages, economic and social, of industrial medical service, and get them to give preference to trained men; while, on the other, the members should themselves arrange for and attend post-graduate courses and so qualify themselves to meet the demand thus created for industrial medical officers. Once sure in this way of their students the schools would willingly arrange instruction. The Association has been calling for years for help from others; here, to-day, is a better way in which they can help themselves and benefit the community.

G. F. SHERIDAN RESIGNS FROM OHIO ASSOCIATION TO BECOME EDITOR

Mr. George B. Sheridan, executive secretary of the Ohio State Medical Association, has resigned to accept the editorship of the Springfield, Ohio, *Daily Sun*.

Mr. Sheridan has served as the executive secretary of the Ohio State Medical Association for six years and has developed a plan of organization which is unique in this country for medical associations.

As a result of his organization work there is probably no state in the union in which the medical profession is as well organized as in Ohio.

The work which Mr. Sheridan has done gives special point to the conclusions reached by him as a result of his six years' experience, which is published in the July issue of the *Ohio State Medical Journal*.

As a layman he does not concern himself with the scientific side of medicine but to organization for the promotion of the public health and the good of the profession.

Briefly summarizing the subjects which he considers of special importance to physicians are:

(1) Protection of the sick public from the ignorant and the crooked.

(2) Protection of the profession against legal shysters who in the past have found the average busy physician to be easy prey for blackmail.

(3) The maintenance of educational standards for undergraduates and the continued scientific improvement of members after graduation.

(4) Protection of the profession from petty persecutions and useless or unfair restrictions, which usually are concocted by half-baked reformers or hostile opponents.

(5) Organized support for intelligent and scientific public health administration.

(6) Maintenance of fee schedules which will make it possible for physicians to render adequate service.

(7) Maintenance of permanent organization framework which will be available for quick mobilization of medical resources in times of local, state or national need.

¹⁰ Colonel Thomas Salmon: Toledo Times, 1919.

*Editorial from *The Lancet*, vol. i, 1919, No. xxv.

AN INDUSTRIAL MEDICAL SERVICE THAT KEEPS 12,000 WORKERS FIT

In both the curative and preventive departments of industrial medicine, The Colorado Fuel and Iron Company, with twelve thousand men employed in its twenty-odd coal and iron mines in Colorado and Wyoming and in the Minnequa Steel Works, Pueblo, Colorado, has adopted advanced standards.

This pretty dental nurse visits the mining towns and instructs the kiddies in the use of the tooth brush.

The service of industrial medicine and surgery in healing the sick and restoring the injured is important indeed, but much more so is its service in preventing disease, teaching hygienic living, and keeping the worker and his family physically fit.

The company's medical department was founded almost simultaneously with the beginning of its operations nearly forty years ago. The department has its headquarters in the Minnequa Hospital, Pueblo. This institution for years has been accorded merited recognition as one of the most advanced industrial hospitals in the United States. The staff of surgeons at the hospital is supplemented by the services of physicians in the various mining towns. Adjacent to the steel works at Pueblo is a dispensary for the treatment of minor illness and injuries. The company has inaugurated a program of building dispensaries or emergency hospitals at the mining properties. Two of these already completed, one at the coal camp at Primero and

the other at the iron property at Sunrise, Wyoming, were donated to the people of the camps by John D. Rockefeller, Junior.

At the steel works and at several of the mining towns, visiting nurses are employed. These nurses care for ill and injured men in case of emergency, but their principal function is in teaching the principles of hygienic living and housekeeping according to American standards to the wives and families of the miners. Within the past year the company has cooperated with the counties where its mines are located in employing public health nurses under the supervision of the American Red Cross.

For the benefit which he and his family derive from the medical service, each employee pays one dollar per month. The fund thus raised is supplemented by appropriations from the company. Employees are entitled to hospital treatment in case of injury or serious illness and to medical service at their homes. In the case of workmen living at the mining camps, free medical attention is also extended to their families. Hospital treatment is not furnished to families of employees free of charge, but a reduction from regular rates is made for their benefit.

More than two years ago a decided innovation was inaugurated in the shape of free dental and optical service

The dispensary maintained by the Colorado Fuel and Iron Company at the iron mining town of Sunrise, Wyo.

for the children of employees. Oculists and dentists visit the public schools in the mining towns and the schools adjacent to the steel works and examine the eyes and teeth of the children, beginning with those in the lowest grades. The teeth are cleaned and, when it is necessary, fillings are put in. The eyes are examined and the children's parents advised if further attention is needed. No charge is made for the dental and optical service. Glasses when prescribed by the oculist are not furnished free, but are purchased by the company at a wholesale price and supplied to the children at cost.

The beneficial effects of the dental and optical service to the children became apparent almost at once. Results in numerous cases have amply confirmed the modern belief that much ill health and even some apparent defective mentality in childhood are due to infected teeth or sub-normal eyesight. With continuous attention given the children year after year, it is confidently expected that the good results will become even more noticeable.

In the autumn of 1915 the company and its employees mutually adopted the industrial representation plan for the government of their relations with each other. This industrial constitution, which has been notably successful in removing causes of friction and harmonizing the interests of employer and employee, provides among other things for joint committees on industrial relations. There

The visiting nurse makes a call at the home of an employee of the Colorado Fuel and Iron Company.

are four of these committees in each of the mining districts and at the Minnequa Steel Works. Of these four, one is designated as the "joint committee on sanitation, health, and housing." Within the jurisdiction of this committee falls the general supervision of health and housing conditions. It cooperates with the medical department and the company management in initiating and carrying out whatever improvements seem desirable.

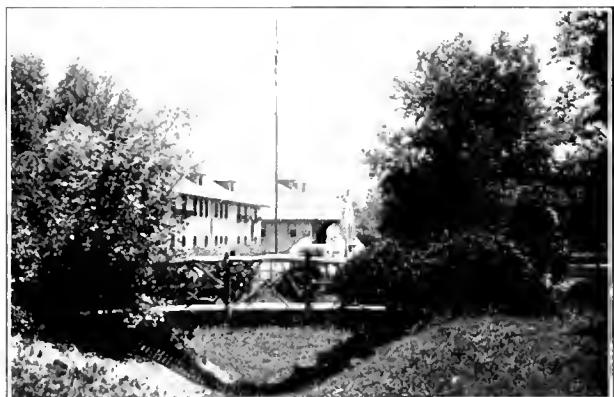

Main entrance to the grounds of the Minnequa Hospital of the Colorado Fuel and Iron Company, at Pueblo, Colo.

The services of the various committees on sanitation, health, and housing have been valuable beyond computation. Particularly in the mining camps these committees have made periodical inspections, minutely examining everything that has a bearing upon the health and com-

fort of the employees and their families. As a result of these inspections numerous recommendations have been made, practically all of which have been promptly acted upon by the management.

The Colorado Fuel and Iron Company believes that the health or illness of an employee generally begins at home. It has therefore given much thought to the providing of modern and sanitary dwellings for its workmen. Standards of housing have been constantly improved. In recent years, as the increased earning power of the work-

A wide expanse of lawn and trees, plenty of sunshine and fresh air, and the Colorado climate give a rare charm to the Minnequa Hospital.

men and their rising ideals of home life have created a demand for even better dwellings, many houses with modern conveniences have been erected at the various properties. The workmen and their families have in the main been found appreciative of the better living facilities provided.

NEW SANITARY CODE FOR RAILROADS

A revision of sanitary rules and regulations is being completed by the Committee on Health and Medical Relief of the United States Railroad Administration, with a view to providing a standard code of regulations for railroad stations, shops, trains, and other properties in all states.

Dr. D. Z. Dunott, chairman of the committee, prepared a paper recently which embodies several of the important conclusions agreed upon by the committee. This paper, which was read at the conference of State and Territorial Health Authorities with the United States Public Health Service, is printed in *Public Health Reports*, July 4, 1919.

The committee offers the following comment:

"The water-closets in railway stations through the country, with but few exceptions, are maintained in a very insanitary manner. At times they are actually filthy and transgress all rules of decency. The washing facilities are not much better. In some stations arrangements are made for a pay service, and when this is the case cleanliness is the rule."

"In large cities the fixtures are in such constant use that it is difficult to find time for cleaning, even when a disposition to that end is shown. In view of the fact that these facilities are used more by the nontraveling public than by the patrons of the railroads, the question naturally arises whether it is quite fair to throw the entire burden of their installation and maintenance upon the railroad companies."

"For the sake of common decency the lack of public toilets should receive early attention. America is the only modern country that throws the burden of providing toilets upon private initiative."

The laundry on the grounds of the Minnequa Hospital lends a delightful aspect to the architectural background.

THE NATION'S HEALTH

Public Health and Public Welfare, Administrative Medicine, Organized Health Service

C. E. A. WINSLOW, DR. P. H., *Editor*

NOTABLE ADVANCES IN PUBLIC HEALTH ADMINISTRATION

IT HAS long been clear that the most serious obstacle to the development of public health work is the lack of trained local health officers; and that it is quite impossible to obtain such trained officials for small rural or semi-rural population groups. The obvious remedy for this condition is the creation of administrative sanitary units larger than the individual town or village, large enough to employ a competent full-time health officer, with the staff necessary for efficient public health work along modern lines. Such a staff, to serve a population of 16,000, must include at the very least a public health nurse and a sanitary inspector in addition to the health officer; and should demand an annual budget of not less than \$5,000.

In the South the problem of effective rural health administration has been largely solved by the development of county health organizations, but in the North the county is a highly artificial political unit which generally escapes the public scrutiny necessary to keep it free from political graft and incapacity. The creation of cooperative sanitary organizations representing adjacent towns and villages has therefore seemed the most promising course in the northern states. New York has for some years had on its statute books a law permitting such consolidations, and has made substantial progress in reducing the number of local health officers within the state, which a short time ago reached the absurd total of 1,200. In 1918 a special act of the legislature (Chapter 174, Acts of 1918) created the Lake George Health District, comprising parts of eight towns and villages to be administered by a board of health of three members elected by the supervisors of the towns and the presidents of the villages concerned. This District has a health appropriation amounting to \$2 per capita, and has already become a model of rural sanitary administration.

A general extension of the principle of consolidation of health districts in the state of New York is provided for in a more recent amendment of the section of the public health law dealing with local boards of health (Chapter 423, Acts of 1919). On the request of the authorities of any towns, villages, or cities the state Commissioner of Health may create a consolidated district to be administered by an unpaid board of health of from three to seven members composed either of the regular officials at the head of the various areas concerned or of special delegates elected by them. Under the general provision of the Act the health officer to be appointed must be a physician who has received the degree of Doctor of Public Health, or "who has completed a course in public health approved by the public health council at the time of his appointment." He serves for four years and cannot be removed from office without the approval of the state Commissioner of Health.

The most important section of this Act is the paragraph dealing with finances, which places at the disposal of the board of health of the consolidated unit an appropriation unlimited except by the public opinion of the electorate which retains its members in office. "The board of health of any consolidated district," in the words of the Act, "may annually make an estimate of the expenses of such board for the ensuing calendar year and, if such district be wholly in one county, shall deliver a certified copy of such estimate to the clerk of the board of supervisors of such county prior to the annual meeting of the board preceding such year. If such consolidated health district be located in more than one county, the board of health of such district shall proportion the total amount of such estimate in the same manner as provided by this section for proportioning the expenses of such a district when audited and approved by the board, and shall deliver to the clerk of the board of supervisors of each county a certified statement of the total estimate and the amount due from the real and personal

property of each town, village, or city of the consolidated health district in each such county on account thereof. The board of supervisors of each such county shall levy a tax upon the real and personal property within such health district sufficient to provide for the portion of the amount of such estimate chargeable to the real and personal property of each town, village, or city of the consolidated health district in each such county. Such sums, when collected and paid to the county treasurer of each county, respectively, shall be paid by him to the president of such board of health and shall be disbursed by the board of health in accordance with the estimates."

This New York law, while merely permissive, makes it possible for any group of communities to develop an entirely modern and effective health service. The Hughes Health District Act,¹ passed this year in Ohio, goes even further and requires the establishment of well equipped health units throughout the state. It is perhaps the most notable step yet taken in America for the creation of administrative machinery for the protection of the public health.

The situation in Ohio has been worse in the past than that in New York since more than 2,100 independent health jurisdictions have existed within the state. According to the *American Journal of Public Health*, the average remuneration for a township health officer has been about \$25 a year. The Hughes law creates a chain of local health districts corresponding to cities of 25,000 population or over (municipal health districts), or to rural areas outside of such cities (general health district). Each general district is administered by an unpaid board of health including one farmer, two physicians, and one lawyer. Each district, either municipal or general, must employ a full-time health officer with at least one nurse and one clerk, all officers being appointed under state civil service; and the state subsidizes each district up to a maximum of \$2,000. Appropriations are insured by the fact that public health expenditures are made a second lien on the revenue of the townships and municipalities included in each district following immediately after public debt charges. The working out of the Ohio law will call for the appointment of 110 full-time health officers "with permanent tenure of office under civil service" with salaries ranging from \$2,000 to \$6,000 per year.

Adequate powers, adequate appropriations, and the trained men to use them are the three essentials of successful health organization. Authority and funds will now be available throughout the

state of Ohio, and in New York wherever local sentiment awakens to the opportunity offered by the public health law. The only question now is,—how soon can the trained men and women be found, competent to direct the machinery created by this far sighted legislation?

Adenoids Handicap One Child in Ten

The United States Public Health Service has prepared a booklet on "Adenoids" in which it is stated that more than 10 per cent of the children of the country are handicapped with adenoids. The booklet is offered for distribution to parents, school authorities, and welfare workers. Failure of parents to have the physical defects of children attended to during infancy or early childhood is ascribed as one of the chief causes of the frequent occurrence of the trouble.

MOTOR CLINIC AIDS CHILD WELFARE

The campaign for better babies will be carried into rural communities with the aid of a traveling motor clinic which has been put into service by the Children's Bureau of the United States Department of Labor. Physicians and nurses will be in charge to conduct examinations of babies and advise mothers everywhere of how to be sure of the best care and treatment for their little ones.

Interior of the "Child Welfare Special," a traveling motor clinic which the Federal Children's Bureau is sending into rural communities to spread the message of the "Better Babies" movement among the mothers on the farms.

¹ House Bill No. 211 (Ohio). This Act will be published in part in a later issue of MODERN MEDICINE.

A CRITICAL SURVEY OF PUBLIC HEALTH TOPICS

- I. Is the Visiting Nurse a Public Health Nurse?
- II. Typhoid Vaccine and the Control of Typhoid Fever.
- III. Railroads and the Public Health.
- IV. Narcotic Drug Addiction—A Public Health Problem.

A REVIEW OF CURRENT LITERATURE AND COMMENT

I—IS THE VISITING NURSE A PUBLIC HEALTH NURSE?

BOTH sides of the question "Is the visiting nurse a public health nurse?" are very ably presented in articles by Dr. H. W. Hill, executive secretary of the Minnesota Public Health Association and Miss Annie M. Brainard, editor of *Public Health Nurse*, in the July issue of that publication.

Doctor Hill answers this question in the negative, and gives as his reasons that the distinctive feature of the service offered by the visiting nurse is concerned directly with therapeutics, that only a small proportion of her time is devoted to instruction other than that which is really therapeutic in character. The public health nurse devotes her time chiefly to the discovery of dangerous conditions, and the taking of and giving instructions in the precautions required to offset the danger. The distinction between the visiting nurse and public health nurse is similar to that which is recognized between the work of the physician and the work of the health officer.

Miss Brainard, on the other hand, contends that a visiting nurse is a public health nurse and offers the historic reason that originally the term "visiting nurse service" included health nursing other than bedside care. Furthermore, she states that three-fourths of the work of a visiting nurse consists in teaching the fundamental principles of public health. A public health nurse may not be a visiting nurse, but a visiting nurse is, and cannot help being a public health nurse. J. S.

II—TYPHOID VACCINE AND CONTROL OF TYPHOID FEVER

THE value of vaccine in controlling the prevalence of typhoid fever, especially in conjunction with certain sanitary measures, is discussed in the *Weekly Bulletin*.¹ If vaccination had not been carried on among the 2,000,000 members of the American Expeditionary Forces, and had the

same rate of infection prevailed as in the Spanish American War, we would have had in this army the appalling numbers of 384,113 cases and 29,266 deaths from typhoid fever. This is a great contrast with the experience of our present army among which not over 500 to 1,000 cases of typhoid fever have developed. In these cases infection resulted in spite of vaccination but only where the degree of exposure was high. Typhoid vaccination is not an excuse for lavity in sanitation, and protection can be broken down by exposure to continuous and large amounts of infectious material.

Sanitation alone, however, will never completely eradicate typhoid fever, because of the residual amount of typhoid fever due to personal contact with cases and with carriers. "Universal typhoid vaccination combined with a feasible degree of sanitary control would yield far better results and cost the community less than the most ideal sanitary system that could be devised. Vaccination would then reach its highest effectiveness because of the coincident protection from gross sources of infection."

The popularizing of typhoid vaccination is urged with the added value that every forty cases of typhoid fever prevented means one carrier prevented.

J. S.

III—RAILROADS AND THE PUBLIC HEALTH

THE effect of the railroads on the health of the country has been the subject for careful study on the part of the Committee on Health and Medical Relief, of the United States Railroad Administration, and some of the findings presented to the recent conference of state and territorial health officers are given in *Public Health Reports*.²

The embankments used in railroad construction often impede the natural flow of water and the

¹ Weekly Bulletin of the Department of Health, City of New York, July 19, 1919.

² Public Health Reports, 1919, xxxiv, No. 27.

formation of pools has resulted in excellent breeding places for mosquitoes. This has led the Committee to believe that the railroads are in part responsible for the continuance of malaria.

Hookworm, typhoid fever, and smallpox are prevalent in the South and the railroads as large employers of man-power draw their labor chiefly from the communities through which they pass. It is the desire of the Railroad Administration to cooperate with state and local health authorities in controlling these preventable diseases.

The sanitation of water closets in railway stations and on passenger cars is also receiving the attention of the Committee. The practically constant use of these facilities by careless and indifferent individuals makes it very difficult to correct the present unsatisfactory conditions.

The display of health posters in railway stations to further the health educational campaign can be arranged for if a standard card, neat in appearance, is prepared. In the past such permission has been withheld.

As an employer of nearly 2,000,000 persons, the United States Railroad Administration is vitally interested in all measures aiming to improve the public health. Its special health committee is particularly anxious to devise methods for reducing the vast army of injured, which totaled 194,000 persons for 1917.

J. S.

IV—NARCOTIC DRUG ADDICTION—A PUBLIC HEALTH PROBLEM

A MORE sane and scientific attitude on the part of physicians and public health workers toward the narcotic drug addict is urged in a very forceful and thorough manner by Dr. Ernest L. Bishop, of New York City, in an article on "Narcotic Drug Addiction: A Public Health Problem," appearing in the July issue of the *American Journal of Public Health*.

Narcotic drug addiction is far more prevalent and widespread than is generally recognized, and it is suggested that there may be as many sufferers from narcotic drug addiction as there are from tuberculosis.

"It is now a matter of established record and proof that narcotic drug addiction is fundamentally a physical disease condition presenting definite and constant physical symptoms and signs, with invariable and characteristic physical phenomena, and that it has associated with it some of the most agonizing suffering known to humanity."

That addiction disease is even more widespread among mentally, morally, and physically normal individuals than among those persons generally

associated with the underworld is also maintained. Some of our prominent men and women are addicts and are striving to hide their ailment on account of the stigma which would be attached to them by an ignorant public, were their ailment discovered.

There is a sad lack of knowledge of the disease facts of narcotic addiction which is responsible for the absence of adequate provision for humane and intelligent handling of addicts, and as a result the sufferers are the victims of unscrupulous persons who offer drug cures for commercial gain only. The legislative restriction in the sale of narcotics, without provision for education and treatment, has resulted in an increase in criminal and illicit traffic in drugs.

It is exceedingly important that the conflicting views and beliefs held by medical and public health workers be carefully analyzed and properly interpreted. The intolerance of the existing schools of workers is especially deplored. Arguing and quarreling about cures and specifics obstruct real progress towards the rational, scientific handling of disease. Due to this state of ignorance, legislators and administrators regard addiction as habit, or appetite, or morbid mentality.

Scientific education for physicians and laymen is the remedy offered to rectify this situation, and health departments are urged to undertake this most important activity.

J. S.

Build Jacobi Memorial Hospital

A memorial hospital is planned by a group of New York physicians and friends of the late Abraham Jacobi, to be erected in Washington Heights in his honor. Plans are being made to conduct a week's campaign for financing the project. Heights Hospital Week will be held November 15 to 22. The board of aldermen will be asked to sanction the campaign. The committee that has charge of the arrangements is headed by Dr. S. Robert Schultz. Washington Heights has been selected as a suitable location for the new hospital because of a shortage in the number of hospital beds in that neighborhood.

DRAFT FIGURES SHOW 5.4 PER CENT VENEREAL CASES

Among the selective service men of the second draft, in which Uncle Sam called one million men for service in the United States army, fifty-four in every thousand had some form of venereal disease at the time of examination upon arrival at mobilization camps. This percentage, equivalent to 5.4 per cent, or nearly one in every eighteen men, includes only obvious cases of syphilis, gonorrhea, and chancreoid. Wassermann examinations were not given. The Public Health Service has prepared a chart showing the relative incidence of venereal diseases among the men from all the principal cities of the country. New England cities, for most part, show a lower rate of prevalence than cities in other localities. Cities which sent large quotas of colored men have high percentages.

THE INFLUENCE OF SEASON UPON THE PREVALENCE OF EPIDEMIC DISEASES

BY C. V. CRASTER, M.D., D.P.H., HEALTH OFFICER, DEPARTMENT OF HEALTH, NEWARK, N. J.

DANIEL DEFOE, in his Journal of the Plague in London, written in 1665, has probably given the most dramatic account of a plague visitation known to literature. "I am now come," he says, "to the month of September, which was the most dreadful of its kind, I believe, that ever London saw."

In all records of epidemic visitations, season has apparently been an important factor in the spread of disease, and,

indeed, the cessation of many epidemics has been entirely dependent upon the changes of weather, especially of temperatures. Cholera during the summer months has swept from Asia to the furthest western boundaries of Europe, ceasing only when the winter snows blocked the water courses and limited the human tide of traffic. The same may be said to the legion of diseases whose onset depends upon climatic conditions.

Seasonal Influence Two-Fold

These factors may act in two ways: (1) by a direct inhibitory action of the lowered temperature upon outside means of infection, as in the case of cholera, typhoid, dysentery, etc.; and (2) as affecting the habits of communities by bringing individuals into closer contact, as in the epidemic diseases of children, measles, diphtheria, and epidemic pneumonia during the months of winter.

Season, however, is not the dominating factor in the spread of any epidemic diseases, for a summer epidemic disease is just as likely to prevail in winter time if other means of spreading infection are present in an unusual degree.

There are, therefore, doubtless many conditions influencing the prevalence of epidemic disease which vary with each infection, but the deciding effect of season in the greater number of our known epidemics must be admitted.

In Parks and Kenwood's *Hygiene and Public Health*, 1902, the seasonal prevalence of cer-

SOME UNSOLVED PROBLEMS

The deciding effect of season in the greater number of our known epidemics must be admitted. There are, however, variations in the seasonal visitations of epidemic diseases which are brought about by other influences than season. In this connection it is to be noted that coincident with the change in the seasonal prevalence of certain diseases, there has been a marked alteration in the virulence or power of the virus to produce its known effect. These and other considerations which bear on the question of seasonal influences should be thoroughly investigated. A more exact knowledge of the subject is needful.

tain epidemics was charted. Since that time undoubtedly there has been some change in seasonal visitation. At that time smallpox had a maximum prevalence in early summer; it is now a disease of any period of the year. Scarlet fever, formerly a midwinter disease, is showing a tendency towards a maximum in the spring. Typhus fever, formerly a disease of winter and early spring, is now virtually extinct; but it may arise at any time if conditions of infection are present.

Coincident with the change in seasonal prevalence there has been seen a very marked alteration in the virulence or power of the virus to produce its known effect. For instance, it is recorded that syphilis was epidemic in the fifteenth century as a fatal and rapidly progressive disease. Leprosy was widespread, differing from its present endemic location. Similarly, within our own times very definite changes have been observed in the prevalence of scarlet fever and measles so as to show decreased mortality in both cases. Other diseases, such as cholera and bubonic plague, still maintain classic symptoms with unabated power to produce immediate fatal results.

Huxley, in "Time and Life," stated that "every variety to which a species may give rise is either worse or better adapted to surrounding circumstances than its parents. If better adapted, it must sooner or later improve its progenitors from the face of the earth."

Susceptibility to most epidemic infections is present in the human race and in a modern community the opportunities for exposure to infection must be legion.

There must, however, be an increasing immunity to the virus of epidemic diseases among men, a supposition very generally confirmed by experimental laboratory tests with the specific virus of disease in animals.

Ascribing then, as is frequently done, our modern immunity from medieval plagues to our knowledge of preventive medicine, due regard must be paid to changes brought about by altered states of body susceptibility.

This would explain the rapid disappearance of some diseases formerly very prevalent, such as leprosy, and the continued existence of others, such as the epidemic diseases of children, against which a sufficient immunity to ward off infection has not been established. The power of the virus to produce fatal results, although diminishing, has in many instances defied the utmost efforts at eradication. Such infections include measles, whooping-cough, scarlet fever, diphtheria, chicken-pox, and mumps—all diseases of early life.

There must be only a few persons who possess a natural insusceptibility, for the vast majority of adults appear to pass through the ordeal of infection by one or all of these common infections of childhood. With the exception of diphtheria, there are no means of ascertaining the existence of natural susceptibility to disease; its absence in the individual is usually only demonstrated by the onset of the disease symptoms.

Seasonal Incidence of Epidemics

The relationship of season to the common epidemics occurring in large communities was studied in a series of cases reported in the city of Newark for the year 1917. This year was selected as being a normal one with no undue prevalence of epidemic diseases. The reported cases were tabulated by age, sex, and color and, to avoid cumbersome figures, a percentage of each

division to the whole number was worked out for each disease.

It is immediately seen that all of the epidemic diseases are present in cities all the year round. A remarkable preference, however, is manifested by many diseases for certain seasons during which the prevalence is high among the susceptible population, and during which actual mortality is increased. On the other hand, the case mortality by month or week in seasons of greater prevalence may be considerably lower than at other seasons.

Scarlet fever is present all the year round. Its curve of seasonal prevalence is highest in March with a descending tendency running through July, August, and September. The case mortality for the diseases of the year was 0.4 per cent of all reported cases. The highest fatality is seen to occur in July, 4.3 per cent of cases. (Table II.)

Deaths from scarlet fever were recorded in January, July and December. (Table I.)

Since the time of Sydenham, few diseases could compare with scarlet fever in its range of prevalence and high mortality.

The present low mortality experienced is either a remarkable proof of diminished power of a virus to produce fatal effects or is significant of altered susceptibility of the individual himself.

Diphtheria Not Necessarily Seasonal

In 1910 the seasonal prevalence of diphtheria was pointed out in the monthly bulletin of the Massachusetts State Board of Health. It was then believed that the maximum of prevalence

was in January with a low summer record. Recent knowledge of the means of spread of infection of diphtheria suggests, however, that the peak of prevalence in diphtheria depends upon other conditions incidental to locality. In the cases under review the maximum of prevalence

few epidemic diseases still exercising undisputed sway in modern communities. It is questionable whether the disease is any less common than formerly, although the mortality appears to be less. The estimation, however, of the mortality from measles is not always as accurate as it may

was in October and November with the low incidence in August (Table I). The case fatality for the year was 5.7 per cent, and it is noticeable that fatal cases were reported all the year round. The deaths, however, were highest in May, November, and December, thus showing a double peak of high mortality (Table II).

An investigation of the deaths from diphtheria has consistently proved the life saving qualities of diphtheria antitoxin. In nearly all the fatal cases investigation showed that although antitoxin had been administered there had been considerable delay in the diagnosis.

A record of 622 cases of diphtheria in Newark, not treated with antitoxin, extending over a period of five years showed a death rate of 23 per cent. The case fatalities among the colored cases were as high as 20 per cent.

Measles Typically Seasonal

Measles has long been known as a typically seasonal disease, the months of low temperature being favorable for its spread. It is usually seen that there are two annual peaks of prevalence, well shown in the cases recorded for 1917. The early spring maximum is in April, 19.4 per cent of cases, and the mid-winter high prevalence in December, 17.6 per cent (Table I).

It may be said of measles that it is one of the

seem for the terminal pneumonia may follow upon measles symptoms so masked as to escape a diagnosis of that disease.

The case fatality for the year was low, 0.2 per cent, and indicates the extreme variability of the mortality from this disease in various years and among different communities. In an outbreak of measles among emigrant children at New York Quarantine in 1911 the fatality rate was 16.7 per cent.¹

The effect of season upon mortality from measles is somewhat striking. Forty per cent of all deaths occurred in December while April, May and June were responsible for the remainder (Table I). The case mortality was similarly highest in December 0.6 per cent (Table II).

Whooping-cough, it is stated, "is uninfluenced by season and weather." The disease is, however, apparently becoming seasonal inasmuch as the greater number of cases have been reported within recent years in late summer and fall months. All seasonal preferences in whooping-cough are lost when the disease follows upon other epidemics. It is, nevertheless, a true endemic disease and is seldom or never entirely absent in large cities.

The minimum of prevalence in the cases re-

¹Analysis of One Thousand Cases of Epidemic Measles, Amer. Jour. of Dis. of Children, vol. 6, pp. 122-130, 1913.

corded was in February, 1.6 per cent, with a curve which steadily rises to the maximum in July, 20.1 per cent (Table I).

The lowest prevalence was in the winter months—January, February, and March—which months account for only 6 per cent of the total. The case fatality for the year was 1.7 per cent, being four times greater than that for scarlet fever. The mortality from whooping-cough follows the prevalence curve with the exception that most deaths occurred in September, 18.3 per cent, two months later than the highest prevalence curve (Table I). In September, also, the highest monthly case mortality was recorded, 3.0 per cent (Table II).

With improved public sanatoriums and the consequent cessation of epidemic typhoid fever in recent years, it has been possible to realize its perennial presence in most cities. The endemic type of the disease is, however, subject to an annual fluctuation with the vacation period emphasised by "vacation typhoid." Commencing with a low incidence in February of 1.8 per cent, there is a fairly even increase till August, when the sudden summer rise takes place with a maximum of 20.7 per cent of the cases in September (Table I).

The case fatality for the year was 15.3 per cent; the monthly deaths were highest in the month of greatest prevalence, September, 35.4 per cent.

The highest monthly case fatality was in November, 36.4 per cent (Table II).

With epidemic meningitis established as an endemic disease it has apparently developed a period of activity during late spring and early summer months. It is seen that 51.4 per cent of all cases were distributed fairly evenly between the three months, April, May and June (Table II). Although the number of cases reported was small, the high case mortality of 63.2 per cent attests to the true character of the infection. Deaths were recorded from this disease in every month, the highest number being in August, 18.6 per cent (Table I) while the monthly case fatality was highest in October and December, all the reported cases in these months ending fatally (Table II).

It is only under very special conditions that the pneumonias are to be classed as epidemic diseases. It may be said that lobar pneumonia is a true seasonal disease, and could not exist without the immediate factors of cold and damp with sudden and rapid changes in temperature and humidity. It is natural, therefore, to find the greatest number of cases in the cold winter months as is the case. The curve of prevalence commences with

a maximum in January, 16.0 per cent of cases, to a low level in August, 2.2 per cent of cases. The case fatality was 24.7 per cent for all cases. The fatal cases of the disease are also more frequent in January, 19.5 per cent of cases; in fact, 48.6 per cent of all fatal cases occurred in January, February and March (Table I). The monthly case fatality, however, is highest in July, 34.8 per cent (Table II).

The bronchial type of pneumonia is not so truly a seasonal disease and has its greatest prevalence during epidemic years. The number of cases of this type of pneumonia reported is only about half of those of the lobar form. The seasonal incidence is, however, similar to lobar pneumonia being highest in the colder months (Table I).

The case fatality is less than lobar pneumonia, 18.6 per cent. The fatal cases occurred frequently in December, January and March, 60.3 per cent of all fatalities. The monthly case fatality was highest in July, 29.4 per cent, in this manner resembling the record of lobar pneumonia.

Erysipelas Subject to Control

Of all the epidemic disease erysipelas is with the exception of small-pox the best example of human control over a once dreaded affection. It is, however, still an endemic disease being reported at intervals throughout the year. The cases are frequently fatal, the fatality for 261 reported cases being 5 per cent. The disease has, however, become more seasonal than heretofore and shows a preference for the cold months, 70.5 per cent of all cases being reported in the first six months.

The monthly case fatality was highest in April, 66.7 per cent, and October, 37.5 per cent.

The seasonal prevalence of German measles resembles very much that of measles. There is a low incidence in January, gradually rising, to a peak in May, 38.1 per cent. It differs from measles, however, in not having a midwinter peak of prevalence. There is no recorded death from the disease.

Mumps as an epidemic disease has a very decided seasonal incidence and resembles measles in having two annual maxima, one in June, 8.8 per cent, and the other in December, 32.7 per cent. The disease is not frequently fatal and the case mortality was only 0.1 per cent of all cases.

Chicken-pox resembles the former historical period of small-pox with its prevalence during winter and spring months. More than half the cases, 62.1 per cent, were reported in the first four months. The prevalence increases slowly till the peak is reached in March, 17.9 per cent, with a minimum in September.

THE VALUE OF THE PUBLIC HEALTH NURSE TO THE COMMUNITY

BY HELENA R. STEWART, PH.B., R.N., SECOND VICE PRESIDENT, NATIONAL ORGANIZATION FOR PUBLIC HEALTH NURSING, NEW YORK CITY

FOR the first time in its history the United States Public Health Service, during the recent war, organized a division of public health nursing and considered the work of the public health nurse one of the essentials to good health administration. To be considered essential, one must fill a need which no other type of person can fill, or fill as well. There are certain branches of health work which public health nurses are especially qualified by their experience and training to do—and do better than physicians or sanitary inspectors, and it was this fact which led the government to consider them as essential to modern health administration.

Public health nursing like all other branches of nursing is not a work by itself, but a very necessary complement to the work of others. If physicians and health officials find the nurse's part of the health program essential, so, too, her success is quite dependent upon their recognition and support.

A Wide Sphere of Influence

A successful public health nurse reaches so many different groups of people that her opportunities for helpfulness are very great. She comes in touch with women's clubs and other private organizations, with boards of health and boards of education, with life insurance companies and social agencies, with city and county officials, and chambers of commerce, with physicians, ministers, and teachers. But best and most useful of all the nurse's opportunities is her welcome in the homes of the people. She gains this welcome through her services in time of sickness, and through her interest in and care of the children of the family. This tangible service can be understood and interpreted in terms of friendliness, so that advice in ways of health is graciously taken.

In backing up the public health nurse and in helping her to perform her daily tasks effectively, the women of the Nation will be backing one of the most vital agents in the struggle against the diseases which threaten the health and prosperity of all of us, and the very life of our children, which is the life of our Nation. No endeavor to promote the public health can attain full success without her. Her offices are not a charity, but a necessary function, and the service which she performs should be placed universally at the disposal of residents in all communities. In rural districts no less than in cities, towns, and industrial centers, is the service of the public health nurse needed.

"In the control of communicable disease, the public health nurse, who will go to each home, show the mother just how to care for the patient, how to disinfect all discharges and all clothing, and how to protect herself and the family and neighbors from infection, will be far more effective than hundreds of printed circulars or dozens of inspectors who tell the precautions but do not actually demonstrate them with

their own hands. Moreover, the nurse, while she is giving such services, often gets bits of information from informal conversation about the personal habits of the family, about recent visitors or trips away from home, and about services being performed by relatives or neighbors; all of which may be of the greatest importance in tracing the source of infection, or preventing its further spread,—items which would seem to the family of too little consequence to tell an inspector."

Nurses in the Venereal Campaign

Forty-four Public Health Nurses were detailed to work under forty medical officers in the twenty-seven government venereal disease clinics established by the United States Public Health Service. Surgeon General Blue says of them, "The work which these nurses performed was of inestimable value. It is not too much to say that without their aid our success in keeping down sickness in the extra-cantonment zones and in making the venereal disease rate in our army lower than that of any other army in modern times could not have been achieved. In continuing our general campaign for health, and this special fight against venereal disease, we depend upon the continued assistance of public health nurses. . . . We depend upon the women of the nation not only for understanding and support, but we depend upon them to encourage

young women to take up the profession of the public health nurse, and to insist that hospitals provide training for nurses in public health service, including work in venereal diseases. In backing the public health nurse, the women of the nation will be backing one of the most vital agents in the struggle against the diseases which threaten the health and prosperity of all of us, and the very life of our children which is the life of our nation."

Health Education Is Health Protection

The foundation of public health protection is the education of the people in ways of health. Some individuals can be reached by magazine articles and addresses, by newspaper talks and health leaflets; but thousands read little and think little. One logical beginning place for public health education is the school. A system which gathers in the rich and the poor, the bright and the dull, the healthy and the unhealthy, presents many complications; but the school is a well established institution through which, because of our compulsory education laws, most of our citizens must pass. It holds the individual in the years when the mind is receptive and when his chief occupation is to acquire knowledge. The children, assembled as they usually are in school room groups of graded ages and mentality, can be reached conveniently and instructed befittingly in matters of hygiene.

There is no better place to teach the prevention of tuberculosis. It is often too late to change the established customs of an adult, especially when his education is absolutely completed and he knows everything. During school years not only the child's mind but also his body is passing through a most important period of growth. Experience has shown that the most effective way of securing correction for the defects revealed by the physician's examinations is for the nurse to visit the parents, explain the trouble, and help them get the remedy. To find a defect means little if the parents are not persuaded to have it corrected, if the child is not taken to the proper place to receive medical care and treatment, if the educational work in the homes is omitted.

In the schools of New York City medical inspection of school children was started by employing physicians to examine the children for communicable diseases and to exclude those who showed suspicious symptoms. Thousands of children were sent out of the schools because of infectious eye and skin troubles, but after school hours they played with the same children for whose protection they had been excluded from the class room. In 1903, of all the written in-

structions sent to the homes by the medical inspectors, only 6 per cent were carried into effect, whereas some years later, 84 per cent became effective under the direction of nurses, who interpreted the physicians' directions to the mothers and taught them to give the treatments ordered. In 1903 there were 57,000 exclusions for minor eye and skin afflictions, while after the introduction of school nurses the number was reduced to 4,000. The medical inspectors themselves were the first to say that their work without the nursing service was futile.

Nursing Service a Necessary Adjunct

An English school physician wrote of his work as follows: "When I first commenced my duties as school medical inspector in Wimbledon, it was impossible not to feel exceedingly depressed and hopeless with the work. As a doctor, I felt quite stranded in the strange atmosphere of an elementary school, coming into contact not so much with actual illness as with the primary conditions which produce or foster it; dirt, neglect, improper feeding, malnutrition, insufficient clothing, suppurating ears, defective sight, verminous conditions, the impossibility of getting adequate information from the children, or a knowledge of their home conditions, and nobody to whom one could give directions, or to help one in examining the children. The only means of approaching the parents was to send an official notice that such or such a condition required treatment, and it was impossible, besides being outside my duties, to carry on any treatment at the schools. My duties began and ended with endless notifications, and there it all stopped as very little notice was taken of them."

Health Nurses for Rural Schools

In contrast to the development of school work in a large city, in our own state the Ohio Society for the Prevention of Tuberculosis, cooperating with the State Department of Health, is employing a nurse to demonstrate public health nursing in the rural schools of Ohio. In one county she visited forty-three schools, gave sixty-five health talks, and examined 517 school children. She found 711 physical defects in these 517 children. And in each instance the parents were notified that the child should be taken to a physician, dentist, or eye specialist for diagnosis and treatment.

In writing of her work in one rural school, she says in part: "I feel that my work in this township has had results which are already showing. In one room five children whose vision seemed to be defective and whom I referred to

eye specialists have already been fitted to glasses. I can't say too much about the children. I love them all. They are so responsive, and I wish you could be around some time and hear them talk to me and ask questions. At a meeting of the parents and the Village Improvement Society the subject for discussion was 'What is the best thing for us to do in our community?' They decided unanimously that they wanted a school nurse. They come to me from right and left to have me tell them about the work and they arrange little meetings of people especially interested in what I am trying to do. I can't tell you how much I am enjoying this work. It does seem worth while when you can see the results forthcoming."

A principal of one of the township schools called up the county superintendent asking if the nurse couldn't stay a little longer. He said that the parents were beginning to realize what it meant and they were "tormenting" him to have their children examined before the nurse left. Some of these very parents had at first objected to her coming.

School Superintendent Approves

The following is a part of a letter received from the county superintendent of schools: "Your announced plan to call Miss C. from our county, March 15, has given me much concern. Since I realize that there are other places with children whose needs are just as urgent, I trust you will not regard this as a selfish move on my part. Our county never had a public school nurse, and for that reason never felt the need of one, simply regarding such work more or less a frill. However, a few boards of education consented to allow us to make a trial this year. Of course, you know what the nurse proposition was in face of the war demands. In fact, we were wholly unable to secure any nurse properly qualified to succeed, even after the boards had given us permission to proceed. Our only outlook for this year was based on the possibility of you being able to send us someone. You sent us Miss C. who is succeeding admirably in developing sentiment and will do a great work if she is given sufficient time.

"The attitude in the communities where Miss C. has been, or is, changing. Interest in other places is developing. The outlook is favorable—more than that. If Miss C. withdraws, March 15, to go to another county do you think the total good done in both counties will equal that done in one, where the acceleration developed in a given community becomes a contributing force in starting things in a neighborhood? Then, too, I know that it will not be understood by the com-

munities if, after our saying so much concerning the work, no attention is given them. Pointedly, I believe the rapidity of the health movement in this county is at stake in the too early withdrawal of Miss C.

"Another matter I wanted to discuss with you was the possibility of us employing Miss C. next year as our county nurse. I remember requesting you to send us a lady with a good personality. This you have done. Children love her. Parents become attached to her. She is sensible, devoted to her work, and morally strong. We want her in this county. We would like a proposition from you now so we can work it out."

School Nursing Not an Experiment

In the large city the school physician came first and soon proved the need for the school nurse. In the small cities and rural communities the nurse has usually come first and shown the need for the physician, the psychologist, the dentist, and the eye specialist, and no system of physical supervision of school children is complete without them all.

"The school nurse is not a passing experiment. She is a vital part of one of the most important of our national institutions. Through her work American citizens are physically fitted to receive the education which in its turn is to fit them for the responsibilities of citizenship. It is her duty to so teach the value of health both to children and parents as to make them realize that its attainment is worth some real sacrifice on their part; it is her duty to strengthen parental responsibility in new directions. It is her duty to strengthen the hands of teachers and physicians, and also to do her part toward making the American school an institution where bodies as well as brains are developed for a life of usefulness."

Public Nurses and Infant Welfare

"Nothing reflects good or bad conditions in a community more quickly than the rate at which the babies sicken and die." There is no branch of child welfare which does not directly or indirectly concern the public health nurse. It is she who teaches mothers in their own homes concerning care during pregnancy, the need for medical supervision, and the care, feeding, and clothing of babies. She knows of the births in her community and can help in the encouragement of birth registration. If a baby clinic or health center exist in her district, it is the nurse who persuades the mothers to bring their babies, and who in cases of sickness urges medical care instead of the following of the advice of a kind-hearted though ignorant relative or neighbor.

No one would think of sending a boy into a profession or a trade without some instruction and preparation, yet most of the young mothers have been sent into their profession of motherhood without any knowledge of the care of an infant or a young child. The high mortality rate of infancy suggests how inadequate is this method of trusting to instinct and the advice of the neighbors. School nurses all over the country are teaching the girls in the higher grades something of the proper care and feeding of infants, and the simple rules of hygiene and health. The knowledge is immediately useful in families where there are little brothers and sisters at home and, later, when these girls are real mothers, they will not altogether forget the instructions received, and can take up their responsibilities with more intelligence than that which their parents possessed. "Visits in the homes, to keep babies well by detecting little symptoms of illness, carrying out the physician's orders in the preparation of food, systematic instruction of physician and nurse in well baby clinics—these save more lives than the most perfectly run baby hospitals."

The Nurse and the Tuberculosis Movement

The public health nurse in the community may be a very active agent in the movement against tuberculosis. In that movement laws have been enacted, ordinances passed, appropriations made, departments and laboratories established, hospitals, sanatoriums and other institutions built and equipped; but before the people are educated to the use of all this, the message of the expert and the scientist must be translated into the simplest terms and taught by patient, painstaking, oft-repeated demonstration. As the treatment lies for the most part with the patient himself and with the way he is willing to live for a year or two, the physician will instruct him, but it is the nurse who visits him repeatedly, trying to help him keep up his courage and determination. The protection of the other members of the family is also her province—to get them all examined, to build up their resistance, if it is low, and to teach them how to care for the patient in such a way that nobody can be infected by him. Getting patients into hospitals and sanatoriums, sometimes securing suitable work for them when they return—all these things take too much time for a physician, too much special knowledge for even the best intentioned relative or neighbor, and yet they must be done and done well.

While nurses do not make a diagnosis, they should be able to recognize the danger signals of cancer and in the campaign for its control help to bring about early consultation and treatment.

They have an opportunity to observe the early symptoms and advise people accordingly.

Public Service Not a Charity

It should be emphasized that a public health nurse, whether employed by a city, county, or voluntary organization, is not an agent of charity. Her work is that of a nurse and a teacher. While it is true that she gives gratuitous service in the homes of the poor, at the same time she should be at the paid service of self-supporting and self-respecting families. With an income of twenty or thirty dollars a week, no family could long afford to pay for the full-time services of a graduate nurse; but such a family need not be an object of charity. It might afford and be willing to pay for a part-time service and so secure the necessary nursing care for the sick member. Municipal and school nurses have done much to disabuse the public mind of its old habit of associating visiting nursing and charity, and to impress upon it the new idea of public health nursing which may well include all classes of people.

The General Assembly of Ohio in passing the Hughes Bill has provided for a health administration which shall include a public health nursing service in each of the districts created by the bill.

Nursing Should Be Universal

It is the ambition of the Bureau of Public Health Nursing in the State Department of Health to see Ohio covered with lines of a public health nursing service like a cobweb on the grass, so that no child or maternity patient, however remote, need go without care; so that the various clinics which the department expects to see established may have the necessary link between them and the home; so that we may have a better protection from tuberculosis and other preventable diseases; for the properly qualified health nurse, going as a friend and with a friend's welcome into clinics and schools and into the homes of the people bringing the individuals to the physician and the physician's message to the people in simple terms which they can understand, is giving a service so great that its extent is difficult to imagine.

DEALING WITH THE MORON

The recurrence of crimes committed by morons in Chicago has prompted the study of the problem by the municipal courts and a committee of citizens. The outcome of recent conferences has been an effort to institute medical study and medical care of this type of defectives and psychopathic delinquents during early childhood and infancy. Sterilization of adult criminals and defectives is advocated by several of the physicians and public officials who participated in the conferences. The committees of legislation, of publicity, and of survey

and educational problems have been named. County Judge Thomas F. Scully, chairman of the citizens' committee, at whose instance the conferences were called, urges the establishment of a special state institution under the control of a state commission which would operate colonies and carry on corrective work in cooperation with physicians, clinics, and schools.

The medical directors of several state institutions attended the conferences and told the results of their experience with defective patients and criminals.

LEGISLATION FOR PUBLIC HEALTH

Veneral Diseases

At least thirty-four governors made strong recommendations in their annual messages to the state legislatures for the passage of measures for the protection of public health, and practically every state in the Union passed some forward looking legislation.

There were many reasons for the special activity in health matters this year, chief among which were the revelations of mental and physical deficiencies shown by the draft, the national campaign for the control of venereal diseases, and the general recognition of the importance of man power in the life of the nation.

The widespread and efficient campaign by the United States Public Health Service and by state and city health departments for the control of venereal diseases, and the prospect of national aid in carrying on the work caused an almost universal approval, and resulted in the enactment of laws in at least thirty-five states. These thirty-five states appropriated more than a million and a half dollars to cooperate in the eradication of venereal diseases. Notably large appropriations were made in Michigan, Kansas, California, New York, Oklahoma, and Washington.

Wisconsin made a large appropriation for the prevention and control of venereal diseases, strengthened existing laws and authorized the board of health to make rules for their control.

Many of the states that had not already given authority to their state Boards of Health to pass rules and regulations to repress these diseases, passed such acts at this session. Probably in no single year on any subject has there been such widespread and drastic legislation enacted. Several states created special detention homes or reformatories for women suffering from venereal diseases. Among these states are Colorado, California and Washington.

State Departments of Health

The year saw the creation of a new Department of Health in New Mexico and the reorganization of other state departments. The new law in New Mexico is comprehensive and contains most of the accepted principles for such departments.

The state of Michigan abolished its State Board of Health and created a state Health Commissioner to be appointed by the Governor and to exercise rather broad power. The state of Missouri also gave broader powers to the State Department of Health, and the state of Ohio provided for eight deputy commissioners of health to be assigned to districts into which the state is to be divided.

The state of Montana re-created the State Board of Health to consist of five members, all physicians, who are to select a secretary who is also to be a physician qualified to practise. After the first appointment, all the Board members are to be nominated by the Montana Medical

Society. Idaho consolidated the state government and, among other changes, abolished the State Board of Health, and put the duties into the hands of the Department of Public Welfare which is headed by a commissioner.

Wisconsin increased her health appropriation and gave added powers to the state Board of Health. Wisconsin fixed the qualifications of health commissioners and deputy commissioners.

Oregon revised the law creating the state Board of Health and gave extensive powers to the new board. Oregon created a state Board of Eugenics and gave power to the board to "protect society from the menace of procreation by giving authority to sterilize feeble-minded, insane, epileptic, and criminal degenerates in certain instances." Oregon gave the state Board of Health complete control over local boards of health in suppressing disease.

Connecticut, also, gave the state Board of Health control over the local health departments.

Vermont provided for district health officers to be appointed by the state Board of Health, and abolished other local health officers.

Functions of Health Departments

The most comprehensive legislation of the year and probably the most comprehensive ever enacted in any state for local health administration was passed in Ohio. That state had previously had more than 2,100 local health units. There were only six whole-time health officers in the state, and local administration was notoriously inefficient. The new law creates a whole-time health department in every city of over 25,000 inhabitants and in districts corresponding to county lines. The State Department of Health may also approve whole-time health departments in cities under 25,000 at their discretion.

The law makes approximately 112 health districts, over each of which there is to be a whole-time health officer appointed by local authorities from an eligible list prepared by the State Civil Service Commission. Appointments are to be approved by the State Department of Health, and the Department is given extensive powers of control over the local officers.

In each of the health districts at least one public health nurse is to be provided, and authority is given for the employment of as many more as are deemed necessary. Each district must provide by itself or cooperatively for a public health laboratory where the simpler tests may be made.

Wisconsin strengthened and defined the powers of quarantine, and includes influenza and la grippe among the reportable diseases.

Washington passed a comprehensive act regulating the sale of milk and milk products.

Nebraska revised and strengthened her laws, creating local boards of health in the counties, cities, and villages.

Maine provided for local health officers in every city, town, and organized plantation, to be appointed locally but subject to control by the State Commissioner of Health.

West Virginia authorized the county and municipal courts to provide whole-time health officers who shall give their entire time to the duties of their office.

Child Welfare Bureaus

Legislation for child welfare was prominent in many states, a natural outcome of the nation-wide campaign by the United States Children's Bureau and the associations

allied with it. At least four states,—Missouri, Rhode Island, West Virginia, and California,—created child welfare bureaus in the state departments of health. These bureaus followed the usual form for such bureaus in a large number of the states which have been created, either by statute or by action of the state department. *Ophthalmia neonatorum* laws were passed in West Virginia, Delaware, and New Hampshire.

Oregon provided for free medical care at the medical department of the state university for sick and deformed indigent children.

Public Health Nurses

A number of states authorized the employment of public health nurses by cities, towns, and other local units. Ohio first authorized the employment of public health nurses and later, in the reorganization act, required their employment in each health district. The state of California authorized the employment of public health nurses in towns and cities.

Wisconsin required every county board within the next two years to employ one or more country health nurses or health instructors.

Rural Sanitation

The state of North Carolina, which to a considerable extent has been of a pioneer in public health matters, and particularly in matters of rural health, comes to the front this year with a most far reaching act to "prevent the spread of disease from unsanitary privies." This Act applies to all residences which are within 300 yards of any other residence, and requires the State Board of Health to license and inspect all privies which are not provided with sewers or with septic tanks. A charge is made of forty cents for each inspection. A department of sanitary engineering and inspection is created in the State Board of Health to carry out the inspection. It is expected that from thirty to thirty-five thousand dollars will be collected from the license fees, which will be sufficient to pay the cost of enforcing the Act. The state is to be divided for the purpose into ten districts.

The state Board of Health is directed to make a physical examination of school children. One-third of the state is to be inspected each year, and an appropriation of \$50,000 is made by the state and an additional \$27,000 by the counties. Considerable machinery had already been created in North Carolina for the carrying on of this work. A new law was also passed making provision for adequate sanitary equipment for public schools.

Special Hospital Provisions

Iowa passed a number of progressive medical and health measures, one of which puts the state far in the lead in respect to the particular type of legislation providing for free medical and surgical care for the adult cripples who are unable to pay the cost of their care. Hereafter in Iowa any such person may be certified to the state college of medicine and may be sent to the hospital or the college, where the best available medical and surgical attention will be given at the expense of the state. Important provisions of the act are as follows:

"Whenever it shall appear to any physician, county supervisors, township trustees, public health nurse, overseer of the poor, policeman, priest, or minister that there is any legal resident of his or her county over sixteen years of age, afflicted with any malady or deformity which can probably be remedied by proper care and medical or surgical treatment, if said person, or the parent, parents,

or guardian, or other person having legal custody of said person, as the case may be, is unable financially to provide proper care and medical or surgical treatment, it shall be the duty of such physician, county supervisors, township trustee, public health nurse, overseer of the poor, policeman, priest, or minister to report the same to the judge of the district or superior court having jurisdiction in the county in which said person resides. Upon the filing of such report with the judge of the district or superior court as aforesaid, he shall appoint some physician who shall personally examine said person with respect to the malady or deformity. Such physician shall make a written report to said judge, giving such history of the case as will likely aid the medical or surgical treatment of such deformity or malady, and describing the same, all in detail, and state whether or not, in his opinion, the same can probably be remedied. Such report shall be made within such time as may be fixed by the court and upon blanks to be furnished as hereinafter provided. It shall also be the duty of said judge to have a thorough investigation made by the county attorney of his county regarding the financial conditions of the said person, or of the parent or parents, guardian, or other person having legal custody of said person, as the case may be.

"If the judge finds that the said person is suffering from a deformity or malady which can probably be remedied by medical treatment or hospital care, and that the person, or the parent or parents, guardian, or other person having legal custody of said person, as the case may be, is unable to pay the expenses thereof, said judge may, with the consent of the said person, or parent or parents, guardian, or other person having legal custody of said person, as the case may be, enter an order directing that the said person shall be taken to the hospital of the college of medicine of the State University of Iowa at Iowa City for proper hospital and medical or surgical treatment.

"It shall be the duty of the admitting officer of the said hospital of the college of medicine of the State University of Iowa, upon receiving any such person to provide a proper bed in said hospital and to assign or designate the clinic of the said hospital to which such person shall be assigned for treatment; and the physician or surgeon in charge of said person shall proceed with proper care to perform such operation and bestow such treatment upon said person as, in his judgment, shall be proper and necessary. A proper and competent nurse shall also be assigned to look after and care for said person during such hospital care and medical or surgical treatment, as aforesaid."

This Act follows a similar act which had provided for care of crippled children at the state college of medicine.

Iowa also created at the state college of medicine a "State Psychopathic Hospital specially designed, equipped, and administered for the care, observation, and treatment of persons who are afflicted with abnormal mental conditions." Iowa also passed a complete state housing law.

Indiana made large appropriations for the creation of a new institution for the care of the feeble-minded. Tennessee established an institution for the feeble-minded.

Idaho made an appropriation of \$140,000 for a state tuberculosis sanatorium.

Ohio in addition to the reorganization of local health departments, passed several important measures. Medical and surgical treatment of crippled children at public expense is provided for. A state board of optometry to regulate the practice of optometry was created. Large

appropriations were made for the establishment of institutions for the feeble-minded.

Wisconsin authorizes any county in the state to establish an out-patient department in connection with the county tuberculosis sanatorium, or a public health dispensary for tuberculosis and other communicable diseases.

Oklahoma provided for three state tuberculosis sanatoriums, and also passed a law for county hospitals.

Wisconsin provides for the appointment in counties where they have county tuberculosis sanatoriums of a director of occupational therapy.

General Sanitary Measures

West Virginia gave important powers to the state Health Department to inspect plans for water and sewerage plants. All cities and towns and persons must submit to the public health council any proposed system of water supply or of the disposal of drainage or sewerage. "No city, town, or village, and no person, firm, or corporation shall establish any system of drainage, sewerage, or water supply system until the same shall have been approved in writing by the state Health Commissioner." Violation of this counsel constitutes a misdemeanor. West Virginia also provided for the free distribution of diphtheria antitoxin to the indigent poor. Provision is made for distributing supplies to drug stores, but no appropriation was made to carry out the Act and it therefore remains a dead letter.

California revised and improved her act regulating the sanitation in labor camps.

Wisconsin made new regulations on plumbing installations, and contractor's licenses, and amended the laws relating to the control of water and sewage systems. Provision was made for the appointment of a full-time sanitary engineer, and the board is given ample power to enforce his findings in the construction and purification of water supplies, the disposal of sewage, and purification of industrial waste.

Matters of Registration

Idaho made requirement for an annual registration of physicians at \$2 each.

California created a new type of medical practitioner called "trained attendants." The State Board of Health is authorized to issue certificates to applicants to care for the sick as trained attendants, and to issue rules and regulations governing such care and to establish and conduct schools for the training of trained attendants.

Nebraska passed an act providing for the regulation of birth and death registration in the state.

West Virginia provided for the creation of a Division of Vital Statistics in the state Department of Health.

Wisconsin provided a legal method for filing delayed registration of birth, death, and marriage certificates so that they may be accepted as legal proof of the birth, death, or marriage. Wisconsin also provided that whenever the parents of a child born, or the bride or the groom in case of marriage, or the deceased person in case of death, resides in any other city, village, or town, the local registrar of such district shall send to the district of residence an exact copy of the birth, death, or marriage record.

Medical Cults

Chiropody was re-defined by a new statute in New York. The definition reads: "chiropody or podiatry shall be held to be the diagnosis of foot ailments and the practice of minor surgery upon the feet limited to those structures of the foot superficial to the inner layer of the

fascia of the foot, the palliative and mechanical treatment of deformities and functional disturbances of the feet; but it shall not confer the right to treat communicable or constitutional diseases of the bones, ligaments, muscle, or tendons of the foot or any other part of the body, or to perform any operation on the bones, ligaments, muscles, or tendons of the feet involving the use of any cutting instrument or the right to use any anesthetics other than local."

New Hampshire passed a new act regulating the practice of chiropody.

Washington provided for a state Board of Chiropractic Examiners and the regulation of chiropractics. Montana adopted by a vote of the people in November, 1918, a chiropractic license act.

Labor Legislation

Workmen's Compensation Acts were passed in North Dakota, Missouri, and Tennessee. Several states increased the extent of medical care in workmen's compensation cases.

Ohio removed the five-man limit and made the law applicable to employers of one or more employees.

The employment of women was prohibited in Ohio in the following occupations: crossing watchmen, section hand, express driver, molder, bell hop, taxi driver, gas or electric meter reader, ticket seller except between six o'clock in the morning and ten o'clock at night, work in blast furnaces, smelters, mines, quarries except in the offices thereof, shoe-shining parlors, bowling alleys, pool rooms, bar rooms, and saloons or public drinking places which cater to men exclusively and in which substitutes for intoxicating liquors are sold or advertised for sale, delivery service or wagons or automobiles, operating freight or baggage elevators, baggage handling, freight handling and trucking of any kind, any employments requiring frequent or repeated lifting of weights of more than twenty-five pounds.

Vocational rehabilitation acts for the reeducation of persons disabled in industry or otherwise were passed in New Jersey, Pennsylvania, and Illinois.

Similar legislation had previously been enacted in Massachusetts placing the control under the Employer's Compensation Commission. The Smith-Fess Bill providing national aid to the states for vocational rehabilitation of the disabled has already passed the Senate and is pending in the House.

SERBIA'S NEED FOR HEALTH AGENCIES

The death rate from tuberculosis in Serbia during the German occupation jumped to the astounding figures of 1,453 in every 100,000, according to a news bulletin released by the American Red Cross. These statistics were gathered by Col. Homer Folks, who recently made an exhaustive survey of the Balkan states for the American Red Cross. He said there are no accurate figures on the ravages of typhus and influenza, but that infant mortality has increased alarmingly.

"Before the war the birth rate of Serbia was higher than her death rate, which meant that despite the inroads of epidemics, her population was increasing at the rate of 85,000 a year," states Colonel Folks. "Now it is accordingly decreasing," he says. "Bereft of her man power and with her women and children organically wasted, the question of population to till the soil and build up the country is a perplexing one, not easy of solution."

Fixing the remedy for this depletion, Colonel Folks recommends the following necessities for public considera-

tion: doctors, nurses, health officers, medicines, hospitals, clinics, dispensaries, organized public health agencies, district health nurses and visitors, facilities for combatting both the usual epidemics of typhus and influenza, and the always present tuberculosis and scarlet fever. Serbia needs money, trained workers, and training schools.

FUNDS FOR PUBLIC HEALTH SERVICE

In the appropriations measure passed by Congress carrying allotments for the support of activities under the United States Public Health Service, there occurs this instruction: "The heads of the several executive departments and other governmental establishments are authorized and directed to submit to Congress not later than the first Monday in December, 1919, a statement showing for the fiscal year of 1919 the activities of their respective establishments pertaining to the public health and the amount expended on account of each of the said activities."

The Sunday Civil Bill passed by Congress appropriates for the use of the Public Health Service the following sums: for pay, allowance and quarters of commissioned medical officers, \$850,000; for pay of noncommissioned medical officers, \$300,000; for pay of all other employees, \$700,000; for traveling expenses of officers officially detailed to attend meetings to promote public health, \$40,000; for light, fuel and water, \$135,000; for furniture and repairs, \$8,000; for medical and hospital supplies, \$85,000; for maintaining the Hygienic Laboratory, \$27,000; for the maintenance of Marine hospitals, \$625,000; for medical examination of all persons so entitled, \$220,000; for shipment of bodies, \$5,000; for scientific books, \$500; for medical, surgical and hospital services for all persons entitled to treatment under the provisions of the War Risk Insurance Act, \$4,000,000; for the maintenance of quarantine service, \$20,000; for the prevention of epidemics of cholera, typhus fever, yellow fever, smallpox, bubonic plague, Chinese plague, trachoma, influenza or infantile paralysis to be spent in the discretion of the President, in any threatened or actual emergency, \$400,000; for field investigation of the propagation and spread of disease, \$300,000; for interstate quarantine service, \$25,000; for special study and demonstration in rural sanitation, \$50,000; for special study in pellagra, \$30,000; to regulate the sale of biologic products, \$35,000; for the maintenance of the bureau of venereal disease, \$200,000; for the improvement of the Hygienic Laboratory \$20,000. Improvements for Marine hospitals are included, as follows: at Chicago, \$121,000; at Cincinnati, \$10,000; at Mobile, Ala., \$60,000; at Savannah, Ga., \$10,000. The medical department of the Army was granted \$52,500 for artificial limbs and appliances for disabled soldiers.

MEDICAL SUPERVISION OF SCHOOL CHILDREN IN PENNSYLVANIA

The most complete data on medical supervision in any state are found in the annual reports of the Pennsylvania Department of Health. This department is authorized to make medical inspection of schools unless the school districts vote against it. There has been an increased interest, and year after year the number of schools that have voted against inspection has grown smaller, and now the inspection covers practically the entire state. For the year 1916-1917, 18,710 schools were inspected. There were employed 995 medical inspectors and the number of pupils inspected was 455,510. The number of pupils

inspected in 1917-1918 had increased to 485,008. Below is given the compilation of figures for the two years 1916-1917 and 1917-1918, showing the kinds of defects discovered:

TABLE NO. I
COMPARISONS AND TOTAL NUMBER OF DEFECTS AMONG PENNSYLVANIA SCHOOL CHILDREN AS DISCLOSED BY SCHOOL INSPECTIONS

	1916-17	1917-18
Pupils inspected	155,510	455,008
Approximately normal	105,059	119,593
Number found defective	349,551	365,415
Single defects	188,111	204,311
More than one defect	161,149	161,104
Total number of defects	581,923	555,986
Treatment advised (pupils)	328,971	340,689

This table indicates that in 1916-1917, 76.7 per cent of the children were found to have one or more defects and in 1917-1918 75.3 per cent.

TABLE NO. II
TABULATION BY DEFECTS, SHOWING IN DETAIL THE RESULTS OF MEDICAL INSPECTIONS IN PENNSYLVANIA SCHOOLS

	1916-17	1917-18
VISION		
Pupils having defective vision	\$6,597	86,944
Right eye only	13,602	13,132
Left eye only	11,089	11,218
Both eyes	58,906	55,665
Total blindness one eye		928
Pupils having other eye afflictions	4,505	5,035
Corneal scars alone	261	1,120
Blepharitis	1,682	1,589
Conjunctivitis simplex	1,147	1,033
Conjunctivitis follicularis	9	5
Iritis	1	3
Trachoma	80	155
Strabismus (special tests not made)	1,057	1,092
Astigmatism	43	35
Blindness from injury (one eye)	225
HEARING		
Pupils having defective hearing	10,709	8,385
BREATHING		
Pupils having defective breathing	21,026	16,241
Slight impairment	16,908	11,185
Serious impairment	2,873	2,757
Mouth breathing	3,225	2,296
Pupils having adenoids (suspected)	5,389	7,927
Pupils having goitre	1,617	1,562
TEETH		
Pupils having defective teeth	281,263	290,684
Unclean teeth	42,709	41,613
Decayed teeth	236,034	249,041
Gums diseased	2,520	2,438
TONSILS		
Pupils having enlarged tonsils	12,1586	123,528
Slightly enlarged	76,814	77,022
Greatly enlarged	16,144	45,066
Acutely inflamed tonsils	1,328	1,440
CERVICAL GLANDS		
Pupils having enlarged cervical glands	27,740	26,473
TUBERCULOSIS		
Pupils reported as having tuberculosis	774	629
Tuberculosis of lungs	327	283
Tuberculosis of glands	367	246
Tuberculosis of bones	45	46
Tuberculosis of joints	35	54
NERVOUS DISEASES		
Pupils having nervous diseases of grave import	513	434
Chorea	450	349
Epilepsy	63	85
Pupils mentally deficient	434	501
SKIN DISEASES		
Pupils having skin affections	6,157	5,721
Impetigo Contagiosa	220	236
Ring worm	60	67
Lupus	3	0
Eczema	497	510
Acne	438	392
Head lice	4,839	4,319
Scabies	26	74
Other skin affections	74	123
DEFORMITIES		
Pupils having deformities	1,733	1,916
Hunch back	35	35
Club foot	69	61
Curved spine	164	142
Ankylosed joint	7	8
Hare lip	25	29
Cleft palate	139	116
Other deformities	1,294	1,495
MALNUTRITION		
Pupils with sub-normal nutrition	5,578	4,860
Slight	4,760	4,078
Marked	818	782
QUARANTINABLE DISEASES		
Pupils in school that should have been in quarantine	41	98
Chicken-pox	20	98
Whooping-cough	10	72
Measles	3	7
Mumps	3	3
Piphtheria	3	5
Scarlet fever	2	0
MISCELLANEOUS AFFECTIONS		
Pupils having miscellaneous defects	513	383
Asthma	18	26
Defective speech or stammering	297	235
Total deafness (both ears)	186	122
Other defects		

PROBLEMS IN SOCIAL MEDICINE

Medical and Health Education, Child Welfare, Social Insurance, Rehabilitation, Medical Law and Allied Subjects

JOHN A. LAPP, LL.D., *Editor*

PHYSICAL GUIDANCE OF YOUTHS WHO GO TO WORK

THE great majority of boys and girls leave school to go to work at fourteen to sixteen years of age. For the most part these immature youths go into employment without guidance, either vocational or physical. They take the first job that they can get without much regard to their physical ability to stand the strain of that particular occupation. The results are apparent to any observer. The robust boys and girls survive and perhaps prosper; the weaker ones are adversely affected, and many break down. The statistics of mutual benefit associations show an abnormal increase of days lost from sickness by boys from sixteen to eighteen years of age which is largely accounted for by the strain of adjustment to the unnatural conditions of employment.

We have committed the grievous fallacy of treating all youth as being equal in bodily strength, and of regarding all occupations as on a par so far as their physical effects upon youth are concerned. Some industrial managers have already recognized the fallacy and understand fully that it is good business policy as well as social justice to protect the welfare of youth entering employment. Many have refused to take immature youth, while some have instituted physical examinations to select all workers.

Organized society has done little to conserve its young workers except in a negative way by means of prohibitive child labor acts. There has been little constructive effort. When boys and girls reach fourteen or sixteen years of age they are left to their own destruction. The laws in effect say that you must not work at all until you are fourteen or sixteen, but after that it matters not what employment you enter, how long you work, how seriously you overstrain, or whether you can live, let alone thrive, under such conditions.

The country can well afford to keep youth from regular employment until the age of sixteen, and it can equally well afford to see that the efforts for the welfare of the children which are so carefully made up to the sixteenth year shall not immediately be dissipated by a "hands off" policy when the children go to work.

It is far more important that the physical guidance of youth shall be supplied than vocational guidance. In the multitude of related work a boy can readjust himself vocationally without serious harm; but in many cases he cannot repair the damage which a few months or years of harmful work may have on his physique.

The clear logic of the situation calls for medical and health supervision of all children going to work to see that they are physically fit to do the work required; to make sure that no physical weaknesses will be aggravated by the employment; and to help eliminate the processes of industry dangerous to health, or at least to modify the risks. Clearly, such medical supervision should continue until he is safely established in industry. It is nothing short of inhuman to permit either the young or the old to work in places which sentence them to deterioration, disability, or death.

There are certain obvious weaknesses in young workers which are now guarded against in vocational guidance. The girl with a nervous disorder would hardly be employed anywhere in a telephone exchange; the anemic youth would be advised against closely confining inside occupations or dusty trades; and the boy with a weak heart would not be advised or allowed to run an elevator. How many unseen weaknesses afflict the million youths who enter industry every year at a tender age only medical science can determine. State laws ought to make provision for the safeguarding of children by medical examinations.

EDITOR.

THE MENTALITY OF CONVALESCENCE

BY CAPT. E. A. BOTT, MILITARY SCHOOL ORTHOPEDIC SURGERY AND PHYSIOTHERAPY, HART HOUSE, TORONTO, ONTARIO, CANADA*

HAVING now before us a panorama of military medical achievement, consider for a moment the mental attitude of the patients concerned, particularly of cases involving the restoration of function. To present this topic in the form of two questions: first, is a patient's conscious reaction to his condition and treatment a matter of any consequence, as a general rule? Assuming for the time being that patient's attitude is not just what the practitioner would desire, many we inquire, secondly, how should this psychological factor be handled? For instance, may it be ignored or be passed over with a casual word of counsel and encouragement, or should a scientific procedure be adopted throughout, i. e., should we accept that mental attitudes, like other symptoms, show great variety and change; that characteristic attitudes result from definite antecedents, that they exhibit certain uniformities in developing, sometimes pass through crises, and regularly respond to certain lines of discriminative treatment, etc.?

Mental Isolation of the Invalid

The undefined term, mental attitude, is not here used as synonymous with any of the "psychical effects" often alleged to be produced on patients by this or that apparatus or drug with which they are deeply impressed. Such phenomena, half mystically accepted by some practitioners, though without any critical or reasoned view of the underlying principles involved, may or may not be a factor in a patient's general attitude. Nor is the term intended as peculiar to those purely hysterical disorders of the war which, perhaps happily, have compelled attention to psycho-technics that were formerly practised only by leading neurologists and psychiatrists.

Again the term is in no way restricted to that difficult group of cases showing a mixture of physical and "functional" involvement that has demanded the team-play of specialists. A broad-

The mental attitude of the convalescent soldier does not differ greatly from the outlook of a man without a country. Not only has he dropped out of ranks; he is wholly detached from the world he once knew. As a soldier he has acquired a habit of mind which magnifies the circumstance of the moment because the change from civilian to soldier consisted in narrowing down the motives under which he may act. Under the compulsion of discipline he put aside the instincts and motives on which his existence had long depended. Personal initiative and responsibility were taken from him; implicit obedience was demanded, and nothing more. To restore his keenness, to find new incentives and new motives, to overcome apathy and establish desire and initiative, constitute the immediate problem of reconstruction.

lances and ether, baths and massage benches, etc., however skilfully these be employed. The condition in large measure concerns voluntary functions which, having once been part of the patient's normal equipment for the activities of daily life, are now absent or seriously impaired, with the result that his life has shrunk to a degree that can accommodate that loss. To restore crippled functions requires the physiological and mechanical basis, but likewise effort, insight, and perseverance by the patient. Formerly these functions operated with ease; now the habit of inaction or of substitution is ingrained and stabilizes a "set" of maladjustment.

In the Depths of a Man's Nature

To overcome the latter is a course of high resistance that is neither natural nor congenial. For this reason a purely impersonal technic is not adequate. The very depths of a man's nature must frequently be reached and stirred in order that he play his part, for without desire and determination we look in vain for effective action. The motives which are fruitful are as various as human nature is complex, and the selection and application of them cannot well be left to a chance environment. Treatment must be fitted to the man as well as to his ailment. The opposite point of view might be illustrated by a type of political economist who in his endeavor to analyze rents, wages, prices, etc., sees not the folks whose deepest instincts give such concepts life. Is the thera-

*Read before the Institute of Medicine of Chicago, May 1, 1919.

peutist safe from the same pitfall until he sees a patient as more than bone and blood? Crude though the family physician's psychology may be, it has a power which specialized medicine can profitably develop and refine. Now, when modern medicine is aiming to carry its benefits of prevention and cure into the realm of organized industry, the time seems fully ripe to stress this point of view in medical education and practice.

The Art of Interviewing

This is not the occasion to present a detailed analysis of the mental attitudes of either military or industrial patients but a few points and illustrations rather arbitrarily selected may serve to indicate certain problems and remedies which our military experience has suggested.

The setting for diagnosis of a veteran's point of view is important. One's mental outlook is not merely a personal possession, but a sensitive, living organism with a life history and unlimited potentialities. It may be guided more frequently than driven. The object of an interviewer is not so much to gain knowledge as to leave an impression, and if possible an inspiration. Interviews should, therefore, be individual and characterized by brevity, frankness, confidence, and a sympathetic understanding conveyed by tone and manner rather than by words. Labored questioning on civilian history and service record serve usually only to confuse, chiefly because the man is accustomed to be paraded and given his report or receive instructions. Facts which his papers would reveal at a glance need not be rehearsed; it is more impressive for the interviewer to show the possession of such knowledge than to elicit it. Man to man contact, eye speaking to eye, has in it a power which should not be distracted by the filling in of forms. From this standpoint the initial interview is a first and invaluable step in treatment. With the constructive phase of the interview we shall deal later. Our present point is the importance of what may be described as the unspoken communication. This does not imply pauses of silence, but it does mean the exercise of a fertile and appreciative imagination which reads accurately the background of the patient's past. This fact is impressed upon the patient by the nature of the program outlined for him.

In the training of civilian workers for functional re-education we have been impressed by the advantages of dwelling on certain features of the veteran's mental outlook. That the veteran is different from the civilian is immediately recognized, but failure to understand how and why is disconcerting and invites indulgence in sentimentality. On the other hand, to give students

a critical curiosity about this side of the case stimulates close observation, assists in adjustment to the needs of the individual, and adds immeasurably to the interest in the work.

This pedagogy must pierce below generalities to a study of individuals. The attitude of a patient depends not merely on what he was before enlistment, but on what branch or branches of the service he has been in and the conditions and length of his service and hospital experience. The outlook of an infantryman differs from that of an aviator, as a counter-battery artilleryman's does from that of a naval cadet off a submarine chaser. A patient's attitude is not simply a product of his hurt or of his hospital environment, but of his whole service. It is habits of thought that make problems of re-adjustment, and for this reason the ultimate cause of "hospitalization" should be sought not in hospitals, but in certain unavoidable features of combatant service. This may be illustrated in an abstract way from the experience of the healthy infantry recruit.

A Narrowing of Motives

Whether he be a draftee or a volunteer, his first job is to learn to be a soldier. To say that this means he loses his individuality and initiative is less accurate than that it means a narrowing down of the motives upon which he may act. "How little," writes a soldier from France, "the outside world understands what our lives are like. In the outside world there are standards of freedom and politeness; in all personal matters a man has the power of choice. He is at liberty to make or ruin himself. He washes if he so desires; if he prefers to go dirty he does not wash. Within reason, as far as is compatible with the earning of his daily bread, he sleeps as long as he wants. . . . With us, everything is reversed. We grow mustaches under Army orders; we crop our hair to please the Colonel. We have no areas of privacy either in our bodies or our souls. We rise, sleep, eat, wash, when we are commanded. We are physically examined, physicked, pumped full of antitoxins, and marked off to church parade to worship God without our wishes being consulted. . . . We cannot give notice to our employers; we have no unions, no means of protests. To be always cheerful and smiling, the more cheerful and smiling in proportion to the hardship is a duty for the performance of which we expect no thanks. . . .

"Success in civilian life demands foresight, judgment, decisions that involve responsibility. All this must shrink to the vanishing point. In ranks I do as I'm told. I do not think what I am to do, but I must think what I am doing. I am

not a good soldier until my critical instincts are inhibited at least to the extent that they do not feel outraged, nor plead for indulgence because of the limitations of my rôle. Nevertheless, room for initiative remains in the giving of prompt and accurate obedience, neither understepping nor overstepping the mark, expecting neither gain nor glory. Precision requires concentration and restraint, and for reward I may cultivate such chronic good humor as I will. This contraction in motives is a moulding process that requires time and adaptation. It is more disagreeable in the learning than when accomplished, but the unlearning seems most difficult of all. With the narrowing of motives necessarily come changes in values, some more significant than others.

Subtracting the Personal Equation

"The personal equation must be adjusted. In civilian life we each adopt a particular point of view to all whom we meet: our banker, our grocer boy, our member of Parliament, our doctor, our aunts, the stranger we pass. We carefully classify and appraise our social environment for what it means to us, and our daily routine becomes a dove-tailing of reactions appropriate to the great variety of our associates. On enlistment this grading of associates is ironed out. We each have our number; we think together, act together, play together; we belong to the dead level of Tommies. Beyond this are no distinctions of person, only of rank, which is for the most part a philosophy of clothes and an appreciation of idiosyncrasies.

"The limiting of responsibility has far reaching effects. In ordinary life our tasks rarely stand isolated; they blend with one another and with the activities of our fellows. Under such circumstances the attainment of results is more significant than the detail of the means employed; in other words, experience counts, discretion is expected, economy in time and effort is approved. In the army tasks are sharply focussed. To concern oneself with more is to be guilty of an offense. Instructions mark the limit both of responsibility and of power. Time means nothing. Ultimate results are not your concern. Explicit obedience to superiors to the last detail is at once your duty and salvation."

This limitation of responsibility the soldier learns too well, he even achieves skill in shifting to others the small responsibility he has. The fruits of this planting ripen during convalescence. His active duty has then ceased, but his attitude of dependence remains and is seen in his cheerful resignation to passivity. He is overwilling to

be managed from without, not from within, even in the matter of improving his condition.

Many of the major moral forces and behavioristic reactions which serve to stabilize society are inhibited or reversed in active service. Habits that make for conservation of life and have been a lifetime in building are changed into a will to risk or take life. Discipline and common sense are not always sufficiently powerful substitutes for the sanctions of the home, the church, or the club. The horrible sights and acts, the verminous nights, the moments of uncontrollable emotion, of fear, disgust or passion, the swift partings, such things which deeply burn,—we who have not been there can know nothing about even though our pulse may quicken over some bit of realistic verse from the trenches. The oscillation between extremes, for example, between periods of work of heart-breaking severity and rest periods of comparative idleness, is probably more of a tax on stamina than the deadliest monotony of industry can ever be. It is not during action but in billets after action that hysteria usually incubates. Too great contrasts inhibit control. The degree to which such experiences reduce the power of re-adaptation to the civilian outlook is in some cases probably considerable, though always difficult to gauge.

Unlearning One's Army Habits

True to the laws of life and growth, the human mind accommodates itself to a change in mental environment. Characteristics which formerly were important tend to disappear and others are acquired. If the change is rapid and extreme in kind as on entering military service, the adjustment is more marked. It is the new "compensation" factors that become dominant. They form the retaining walls in a new level of mental equilibrium; they are the foundations of successful training and of high morale so long as the environment of active service continues. Should a different setting arise as during convalescence or at discharge or, more generally, when the armistice was signed, the equilibrium is again disturbed. If, for instance, it be a question of re-entering civilian life, the problem of adaptation is two-fold, *viz.*, the reinstating of discarded motives and the reduction of those which have sustained him through the hardships of service. The re-learning is here easier than the unlearning because the latter motives are founded on the most primitive and strongest instincts in man.

Perhaps the most dominant compensation factors in military life are those instincts which make possible and stable a gregarious male existence. One has but to reflect on the satisfaction

with which we seek the seclusion of our home or club after but a few hours in the company of our business associates to realize what adjustments would be required for us to live congenially elbow to elbow for months on end with men not of our own choosing. These adjustments are both discriminative and assimilative. A man who is not in harmony with the group has to be discriminated against as a menace. He is ostracized in countless ways by his fellows. If the satirical remark or practical joke are not sufficient, plain words or forcible action must follow. What in ordinary society might be a harmless eccentricity becomes an intolerable nuisance or danger in gregarious life. The herd cannot escape from the offender; it must, therefore, cure him. This is the negative or protective phase of adjustment.

The Root of *Esprit de Corps*

The positive or assimilative phase of the gregarious instinct is that comradeship of companions in arms which is as old as war. It is not based to any large degree on the luxuries or pleasant things of life, on any similarity of tastes or hobbies. It is not a partnership, there being rarely anything to apportion. Its external side is simply a common inheritance of hard marches, wet trenches, good gourmets, and, withal, cheery smiles. Fundamentally, this comradeship rests on the feelings and aspirations of a whole body of men who have a common and hard lot, and who know that while they may fall before it one by one they cannot rise above it except together. The feeling is not one of liking the task; the aspiration is only to see it through. Every good officer knows that this factor is a corner-stone in the structure of *esprit de corps*. With this feeling strong within him no can hold back when his comrades go forward.

Nevertheless, though this comradeship has been vital to the Army, helping the men stand shoulder to shoulder in the trenches, its usefulness is not so evident on return to a civilian setting if it tempts men to sit side by side on our park benches when work is to be had. To modify a strong instinct on which one's existence has long depended is surely as difficult as to master a trade. The quality of human nature which produces the companionship of the trenches likewise produces veterans' associations and trade unions; it may be guided, it cannot be repressed.

Two instincts of expression which gregarious army life fosters and is for are fighting and playing. The one is an unpleasant necessity, the other a pleasurable substitute or equivalent. That the play instinct, as expressed in physical sport, seems spontaneous in our Army and is suggestive

of a fruitful means of stimulating physical action in crippled men whose fighting days are over. There is also a current of playful humor that flows near the surface in the Army. It may be shallow, because a herd is never intellectual, but it is expressive, and is one of the ways of relieving the feelings and of passing the time congenially. In this connection we should not fail to appreciate the extent to which poker and craps helped to win the war.

Mentality of Military Convalescence

We have referred to some factors in the soldier's mentality, whether he was physically incapacitated or not, which must be reckoned with in rehabilitation. May we now consider certain influences these produce in the outlook of the wounded man and then formulate the problems and remedies for the peculiar mentality of military convalescence?

Until the soldier falls out his existence as an individual is nil, then all of a sudden he becomes important. He is no longer told what to do; he receives attendance, others act for him. His companions have gone forward, he goes back. No longer has he to keep pace with anyone, he is out of the race. This is a complete change of setting and produces a corresponding mental reaction. Realization of his "blighty" is the occasion of profound relief that knows neither reservation nor misgiving. The positive forces fall away without compensation. Unlike the civilian casualty who feels the distressing responsibility of provision for his family and himself, the soldier is aware that provision is assured. He calmly waits for what the future may bring forth.

A Slump in Mental Tone

The initial and most significant point in his mental adjustment is this unresisted slump in his "reaction of effective capacity." Whether his hurt be grave or slight, there is now no appeal for action either from without or within. From a circumstance wherein he strained every nerve to fall not short, he has fallen suddenly to a level where no goal exists. This slump in will is, of course, not peculiar to the war casualty; it may be seen on every hand in civilian life; in the school child who loses his place through unavoidable absence; in the laborer who loses first his place then his inclination to find another. But in the soldier, owing to his mental antecedents, the slump is more striking and the restoration of positive values more difficult. A new outlook has to be created, perhaps in the face of the fact that it was not a healthy thing to get well before the armistice. To restore his keenness, to find a

motive appropriate to his state of mind is then the immediate problem of reconstruction.

The soldier's habit of not assuming but avoiding responsibility inculcated in his days of service finds full indulgence during convalescence. He takes his treatment with philosophic complacency. He is more satisfied to be worked at than to help himself. The remedy again lies in altering the point of view.

Danger of Mental Depression

The convalescent Tommy is surely the most impressionable of men. Since enlistment his sphere of action has been narrow, with little variety or complexity. Situations which formerly he would have carefully weighed he now interprets only with himself as center. Not understanding the mysteries of medicine, he has more than the usual reverence for the opinions of his medical adviser. The latter, being usually at pains not to enlighten him, leaves his uncritical imagination free rein. A doctor's prestige rests partly on a patient's vague alarms, and the fears of the military patient incline toward pessimism. He interprets the most casual and even irrelevant remarks as pertinent to his own case. He regularly selects only the unfavorable indications and the resulting picture is gloomy indeed. If he quotes you an earlier prognosis it is one that harmonizes with his present view and is usually attributed to an officer of wide reputation who is at least two higher ranks than yourself. Such an attitude is not morbid, but a natural outcome of his service experience; it is an attempt to rationalize his passive conduct. The remedy must be through motives that are sufficiently powerful to appeal.

Though the soldier's pessimism is self-centered, he does not keep it to himself. The gregarious habits of active service are a suitable soil for the growth and spread of his deepest feelings. Unless careful counter measures are applied a depressing atmosphere of convalescence becomes the prevailing tone of the hospital. The patient sees little to hope for and applies frequently for leave or even for discharge.

When a patient does show interest about his own improvement not infrequently it is a misplaced interest. He shows a keen belief and confidence in some irrelevant apparatus or technic which is not available, and at the same time he is not inclined to be a partner in what is being done for him. If he is being treated with a galvanic battery he feels that a certain violet-ray machine which he once saw is what is required. Or, if his amputated stump is weak from want of graduated exercise so that he cannot operate his artificial

arm, he complains that the latter is useless. He knows, too, of a high priced American arm that is satisfactory; the Canadian government cannot make proper arms anyway; he hands in an application for leave and intends to cross the line and buy one.

The mental mechanism in this attitude is neither morbid nor unusual. We tend to ignore, to put away, and forget what is highly unpleasant. For him the unpleasant is the manifest disability which stands between him and comparative health. He does not face the facts. In turning aside from his crippled function he ignores or belittles the measures which might bring relief. Instead he pins his faith to something which is just over the horizon or always falls short of being of any practical use to him. This becomes an imaginative construction which he amplifies and garnishes to his liking, and in proportion as his false ideal grows so does his inclination to help himself in any practical way decline. A danger therefore in any program of treatment based on the principle of helping a patient forget his disability is that it aggravates this inclination toward self-deception and the way of least resistance which is already a chief difficulty that he has to combat.

Principles of Treatment

Such factors as the above, the slump in desire for accomplishment, the resignation to circumstances by the individual and the group, the rationalization against self-help, and the forgetting of the real issue in lieu of a false one—these may serve to indicate our problem. Not all of them appear in every case or in like degrees and the attitude varies as the physician condition changes, but observation of 1,000 cases has satisfied me that they play an important rôle.

In referring to principles of treatment as relative to the mentality of convalescence it is assumed that the medical, surgical, and passive therapeutic needs are being attended to, and that active functioning preliminary to more complete rehabilitation is required. The program should be fitted to the patient's point of view as well as to his physical condition. "The invalid," says Prof. E. J. Swift in his *Psychology and the Day's Work*, "who waits till he feels able to work will never begin." The same may be said of the beginnings of functional restoration. Let us accept further that the test of effective procedure is two-fold: first, to reduce his disability of useful function to a minimum in the least time, the claim for as quick results as medical safety permits, being not merely economic but because success is the best stimulant to a patient's effort;

second, and so far as possible, simultaneously to restore his self-confidence to the maximum and to direct and fit him to an objective in civilian life.

The value of curative occupation is now widely recognized on both sides of the ocean. It is properly argued that, man being a manufacturing animal, from the day the patient owned his first jack-knife, and even earlier, he has been making things. Therefore, develop the motives of making with the infinite wealth of originality that that field opens. Interest the patient in things, jobs, objective results. Let his hands be occupied and his mind will be taken off himself. To those who are following military work the validity and results of this principle need no argumentation.

But human nature is very complex and may be approached from various angles. Visible products of his hands are not the only things that stir in man the conviction of accomplishment. If it is instinctive to mould clay into marbles, it is just as instinctive to play marbles—and more energetic. The motives of *doing* like those of *making* have unlimited possibilities of appeal. The problem in convalescence being to overcome apathy and establish desire, it is not so much what he does as the source of his effort that matters. In this sense the merit of a method is its fitness to touch the springs of action. It is because the motives of individual expression have been repressed and those of group effort have been made dominant in the service that through the latter curative action may be stimulated.

Mental Rehabilitation

In this way it is possible to approach the patient's disability and attitude directly and present a constructive program of applied exercise. In the initial examination and interview, pains are taken to have him see the exact deficiency of function in range and in strength as compared with the normal. The problem that stands between him and health is then squarely before him. Challenge him to undertake the task and you arouse his fighting spirit. He volunteers. He is told that he will be shown what to do and how to do it, but that he must do the work. It is impressed on him that the object is to improve his condition, and he is warned that he will get out of the treatment just what he puts into it, nothing more, and that his progress is going to be watched. Few patients indeed fail to respond with their heartiest cooperation. Should this occur the reason lies still in the mental attitude and must be sought out and met. Re-examination and systematic supervision are as important as the initial interview in cultivating the proper attitude.

A complementary side of this direct treatment

lies in the proper equipment and trained personnel to administer graduated exercises suited to various disabilities. With the details of these methods, the progression through muscle-function training, higher coordination and collective gymnastic work we need not be concerned. Suffice it to say that the aim throughout is to combat the attitude of invalidism by setting precise tasks, not minimizing difficulties, and appealing to the strong motives of mastery, of self-competition, and group competition. The results have been most gratifying.

To sum up the principle of the direct method as a remedy for the mentality of convalescence: for each negative element of the latter is substituted a positive one based on powerful emotions which the veteran knows. Instead of allowing the patient to relinquish responsibility he is forced to assume it by having him measure up to expectation in working out his own salvation day by day. His extreme suggestibility is taken advantage of to impress a constructive program stimulated by the instincts of sport and competition. His false idealism which would forget the facts and look for relief to something outside or beyond reach is banished by converting him to an enthusiastic use of practical means at hand. Lastly, his strong gregarious habits are utilized to cultivate an atmosphere of cure rather than of convalescence. Establish the conviction of improvement in individuals and it will spread through a whole patient population; then collective treatment may complete the process.

The time has probably not yet come to draw final conclusions regarding the relative psychological efficacy of different methods of treatment during convalescence. Though the war experience has been large the opportunities of careful comparison of distinct methods, conducted to the same end and under similar circumstances have been few. One's opinions consequently reflect chiefly one's own practice. It might be objected, for instance, that in the direct method of functional restoration men are asked to concentrate on insignificant and unmannish tasks, and that these will only emphasize the disability in their own eyes. But the criticism reflects the standpoint of the well civilian rather than the military convalescent. In the struggle for improvement small things to him loom mountain large, and that which impresses him is what he does accomplish rather than what he does not. On the other hand, the direct method, being intensive, should be tempered by occupation and objective tasks.

Among the problems of the future therefore will be the proper balancing and interrelating of technics that will be most appropriate to convales-

cence in the widest sense. The mental attitude of patients in war service is complex, but is immeasurably simpler than the points of view met outside the service where patients of both sexes and all ages await similar assistance. To find the facts about the attitude of workers in in-

dustry, for instance, is a vital task today that is little more than commenced. If medicine, therefore, sees new service in the field of industry, ought not the psychological factor to have a place in its program and an influence on its therapeutic procedures?

SOCIAL SERVICE FOR THE CHRONIC

BY S. WACHSMANN, M.D., MEDICAL DIRECTOR, MONTEFIORE HOME AND HOSPITAL, NEW YORK, CITY*

THE relationship is so apparent, and its operation so constant and universal that it need hardly be emphasized that among the causes of poverty and dependence, sickness takes a very prominent place.

Both laymen and physicians are in the habit of dividing diseases into two groups, acute and chronic. However, the dividing line is not as distinct as one might imagine, because very often the acute stage of a disease gradually passes into a chronic, lingering form; or a lasting disability may be the result of a violent, acute disease. Only a few ailments present from the beginning the characteristic symptoms of chronic disease—slow development with remissions and aggravations, terminating in more or less complete disability.

The effect of the two groups of diseases upon the social and economic life, which is of paramount interest to the charity worker, shows marked difference.

Two Problems Involved

Two distinct problems offer themselves in this respect and have to be dealt with accordingly. The acute diseases, which, for our purpose, must include accidents, have one feature in common, *i. e.*, suddenness of onset. They befall the individual and the family like a thunderbolt from a clear sky.

When an acute illness makes its appearance in a well established family which possesses a fair amount of economic reserve, the actual physical suffering and, more especially, the mental anguish are great. Considerable disruption and disturbance of life's routine takes place; but, inasmuch

A TASK TO FULFILL

The parties to the obligation:

- The chronic invalid.*
- The social worker.*
- The physician.*
- The invalid's family.*
- The sanatorium or hospital.*

The obligation:

- To secure to the invalid and his family the fullest benefits of modern medicine, social service through family co-operation, and industrial therapy.*

The task:

- To lighten the economic weight upon the home that shelters an invalid.*
- To alleviate the distress occasioned among other members of the family.*
- To supplement home facilities for the invalid's care.*

as acute diseases generally run a short course which can be measured by weeks at most, the financial balance is not seriously upset and, after a little enforced economy, the family finds its level again without the aid of charity. But if such a family happen to be just on the borderline of economic independence, when an acute sickness befalls, in particular, the mother of several children and, in some other exceptional

cases, the charity worker may have to step in and straighten out the upset household.

Whether financial aid be required, district nursing, or temporary child care be needed,—in all cases of acute illness in a family the aid must come immediately; there is no time for prolonged investigations; help must be given speedily, fully, or it is of no avail, and even from an acute illness lasting damage may follow in an economic sense. Fortunately, the social service to be rendered in acute illness is rather simple and can, perhaps, best be summed up in a few words; hospital, doctor and nurse, food, fuel, and money. Some or all of these items are required and have to be supplied.

Much more complex is the situation in cases of chronic illness. Here the economic importance for the family by far outweighs that of the acute cases. Speaking of the wage earner first, it goes without saying that when the loss of wages extends over months and years the problem is entirely different than in the other case, where it is a question of weeks.

The next point is that of disability and need of care and treatment. In those cases in which the

*Read before the National Conference of Jewish Charities, Atlantic City, N. J., May 30, 1919.

chronic invalid is helpless, the family not only loses the income from wages, but another member of the family has to devote part or whole time to the care of the invalid, and the income of a second wage earner is either lost or considerably diminished. The extension of such conditions over prolonged periods naturally tends to affect the income situation of the family to a very serious degree.

The Invalid a Family Handicap

Even in cases of children, a chronic disease upsets the life of the family in a most unpleasant way. Aside from the financial standpoint, the presence of a chronic invalid in a family seriously interferes with the daily life in a great many ways. Assuming, for instance, that a chronic invalid has an annoying cough, a gloom would be cast over the other members of the family and visitors will quite often keep away for fear of infection.

If the chronic ailment is a very painful one, the constant groaning, crying, or other expression of pain, according to temperament and disposition, will not add a very cheerful color to the daily life of the family. The working members of the family may be disturbed in their night's rest and gradually lose in their efficiency and bread-winning capacity. Furthermore, the prolonged woe-riment of the mere thought of having an invalid in the house will weigh the mind and cannot help but affect all the members of the family, whether they are at work or at play.

Common Causes of Chronicity

Chronic invalids may suffer from any one or several of the following afflictions:

Diseases of the nervous system, that is, the brain and spinal cord, such as one-side paralysis, shaking palsy, locomotor ataxia, and other organic diseases affecting the central nervous system and the peripheral nerves.

So-called "functional nervous disorders," like hysteria, neurasthenia, and psychasthenia are also referable to the nervous system, although we do not know the exact nature of the lesions as far as the brain and the spinal cord are concerned.

Chronic diseases of the joints, such as rheumatism in all its varieties, gout, etc., are other causes for chronic disability.

Bright's disease, diabetes, and such diseases of the heart-muscle or valves, as well as the hardening of the arteries, and other diseases of the blood vessels are disabling more people at present than ever before.

Non-infectious diseases of the lungs, such as asthma, emphysema, and various types of chronic

bronchitis will prevent people from earning a livelihood and make the afflicted a burden to the family or community.

If also are considered cancers and other malignant tumors which, in their development, extend over a more or less prolonged period before they lead to death, there will be included the majority of chronic diseases, with the two exceptions of consumption and insanity. These two diseases present such distinct problems that they have to be considered separately and they cannot be disposed of under the general heading of chronic diseases.

We might mention the chronic diseases of children, although one may say they are no different from those of adult life, which is quite true within a certain limit; but there are some special features to the problem of the child chronically ill which will confront the social service worker who is engaged in child care. It would, of course, be beyond the limits of this short paper to dwell upon all possibilities of children which may and will concern the social worker, but the two largest groups, those made up of cardiac children, and the many victims of infantile paralysis, are chronic ailments which make very heavy demands, and the discussion of these will serve as examples of chronicity in children.

Problems of Invalid Children

It goes without saying that whenever there is any complication of a medical nature, that is, whenever disease is at the bottom of a case, the first step to be taken by the social worker is to get in touch with the proper medical agency, whether it be a dispensary, a hospital, or individual physician, for the sake of insuring the proper diagnosis and treatment.

In the case of the cardiac child, the social worker's main duty consists in preventing decompensation after the child has been discharged from active treatment. This is done by instructing the parents as to what is most likely to endanger the child and, therefore, is to be avoided.

These children should, first of all, live on or as near the first floor as possible because climbing stairs is one of the exercises that makes the heaviest demand on the leaky little pump called "heart." Next in importance is the child's supervision in school and at play, and an occasional presentation for a physical examination. Diet is not of paramount importance if one keeps in mind that overloading the stomach also puts an extra load on the heart.

The other large group of children with chronic ailment represents those little patients who have survived infantile paralysis, with one or several

extremities weakened or totally paralyzed. Here also the best friend of the social worker will be the physician and nurse; but there is enough to do for the social worker to help the poor little cripples. The family needs to be impressed with the importance of regularity in the treatment; transportation has to be provided; the child must be educated; and, finally, recreation and amusement must be provided for so as to make the children as happy and comfortable as possible.

Medical Supervision Essential

The care of the adult, also, will have to start with the actual medical side. After the physician or dispensary has notified the social worker as to the necessary treatment, it is for her to see that treatment can be carried out financially and otherwise. If climate is considered the essential factor, the social worker will try to arrange for opportunities to earn a living in a suitable climate, and a great deal of correspondence may become necessary. If damp dwellings appear to be the cause of disability from chronic rheumatic afflictions, naturally the family will have to be moved to more suitable quarters. If under-nutrition makes the invalid anemic, this can be removed by providing supplementary food. Cooperation with the physician, of course, is indispensable in all these matters, but the deciding feature in all the problems concerning the chronic invalid outside of the institution will be the financial element.

As stated before, the economic burden placed upon families by chronic diseases is the partial or total loss of wages of the patient and that of an additional member of the family. To make up for this loss, or to minimize it, may be the very difficult task of the social worker.

Here a sharp distinction is to be made between those who are helpless to the extent that they are bedridden and have to be fed, and those who are partially disabled but under favorable conditions can be taught to earn at least a part living. In the first group the social worker will be confronted either by a situation in which the only solution is transportation to a suitable institution, or in some cases, district nursing may relieve the incredible hardships which the presence of a helpless invalid inflicts upon the family.

Facilities Requisite for Care

The ordinary dwelling facilities were not intended to house such invalids. They require a certain floor space, cubic space, ventilation, cleaning and bathing facilities, and the absence or insufficiency of such provisions creates the most unsatisfactory conditions. There are, of course,

not enough institutions to offer a bed for every helpless invalid, and the social worker will have to tax her ingenuity to ameliorate conditions with the facilities at hand. The family must be told that the invalid must not be hidden away in the darkest and smallest room, that the parlor is barely good enough for him; the importance of soap and water, and of fresh air, must be emphasized over and over; hospital supplies must be obtained for the family until finally it is possible to have the invalid admitted to an institution, where the proper care can be given.

More hopeful is the situation in such cases where the invalids are only partially disabled, where they can sit up in wheel chairs, or limp about with the help of canes or crutches, or where there is enough mentality left for occupation or utilization.

Psychic Factors Add to Difficulty

Every case of chronic disease is complicated by a condition which may be called neurasthenia for lack of a better name for the condition. The change from the normal life to that of an invalid produces in the entire make-up of the chronic invalid results which cannot be explained by physical changes only. Chronic invalids become irritable, morose, sentimental, and show other psychic changes. The cure for these changes involves the whole subject of occupational therapy, a phase of the matter which it would be impossible to even outline within the scope of this paper.

Of still greater benefit it will be to the patient if a way can be found to convert all that is left of his earning capacity into financial returns. This great problem of reconstruction which is confronting all the nations of the world now after the war should call our attention to the fact that the problem is as old as industrial life. We have had with us from time immemorial those who for one reason or another have fallen by the wayside but who are not entirely ready for the scrapheap, and in whom there is enough of an earning capacity left to be of use for the double benefit to themselves and to the community. The social solution of this problem offers almost insurmountable obstacles and, in all probability, there is more than one solution.

Samaritan Quarter a Solution?

My work, which has been concerned with the chronic invalid for the last eighteen years, has compelled me to seek a solution, because I have fully realized that it will never be possible to build institutions large enough to house all chronic invalids. One problem most vital in dealing with

this matter is the question of transportation. The inability to travel even short distances has been a great handicap to the chronic invalid. It is the entering and leaving a house, the question of streets, the climbing of stairs, which most invalids cannot do and which prevents them from successful competition with the able-bodied workers. No amount of education, training, or specializing will eliminate this great handicap, and the eternal question in the case of the chronic invalid, as well as the rest of the industrial world, is to bring together the work and the worker.

My own individual solution would be the establishment of a Samaritan quarter for each community, large or small, where all families could gather who have chronic invalids with them, or who are willing to take care of them under the most favorable conditions. The feature of this Samaritan quarter would be that the main streets for the traffic of vehicles would be depressed below the surface, the roads for pedestrians, or wheel chairs, on a level with the first floor;

the houses in reference to doors, floors, and bath rooms would be so constructed that wheel chairs could negotiate them. In this Samaritan quarter factory building should be located which, by similar modification of construction, could be made suitable for the employment of cripples.

It has been my misfortune that my field of activity is the largest city in the country, and that the creation or construction of a Samaritan quarter large enough to take care of the needs of the Jewish community of New York City would be an undertaking too big to be handled by any existing agency of private philanthropy, or by any individual. A smaller community, perhaps one of the many cities whose charities are represented here, might find it advantageous to try the solution suggested.

Full justice cannot be done to the huge problem of social service to the chronic until it is considered in all of its phases by the proper agencies and handled by society as a whole as perhaps the greatest problem of philanthropy.

HYGIENE IN MARSHALL ISLANDS

The influence of the war in stimulating the public conscience of every nation to the need for attention to matters of public health, has spread even to the small countries and backward places of the world. In the far East the war has created interest in preventive medicine, as

medical men have learned new methods and are applying their new knowledge. To the credit of Japan, it may be said that this nation is doing much to promote modern ideas of health protection among the island peoples of the orient.

The photograph reproduced on this page shows a Japanese

Dental Clinic on the Marshall Island. The photograph shows a Japanese dentist working in the open air on a native and several patients awaiting their turn. (By International Film Service Co.)

in other countries. The returning soldier who has fought with the Allied nations has learned the methods of army medical officers in combating sickness and disease. The

STAMMERING AND MODERN MEDICINE

BY ERNEST TOMPKINS, M.E., PASADENA, CAL.

THE beneficent possibilities of modern medicine may be seen from consideration of an illuminating example. Ever since the race began to raise itself by means of speech above its purely animal nature, that speech has been beset by the mysterious disorder, stammering, both the affliction and the mystery of it deepening as civilization advanced. What will modern medicine do for this affliction?

A broad survey of the question will disclose the fact that all over the world this impediment in the speech prevails to the extent of 20 per cent of all children. The affection makes its appearance soon after they begin to talk, but subsides in a considerable percentage, especially in the girls, but persists in from 1 to 2 per cent of the boys. The usual efforts at correction are of very doubtful utility. It forms a serious handicap to approximately one out of a hundred of the bread winners and defenders of the race; because of it they are unable to do their part in either capacity, but are haunted by a wretched dread that embitters for them what little participation they do have in social life.

The Affliction Becomes Intolerable

The loss to society due to this universal affliction is no longer tolerable; it should not be allowed to grow into a life affliction in so large a percentage of the human race. That so much effort has been expended on less serious afflictions and almost none on this severe malady shows a lack of appreciation of the magnitude of the problem. It is to the discredit of science that for thousands of years almost nothing effective has been done toward relieving the sufferers, and that most of the efforts made have been misdirected.

Could there be any greater inefficiency than to allow so tenacious a disorder to persist for years, and then experiment with cures of unproved efficacy, cures which perhaps involve

30,000 STAMMERERS MAY BE SAVED ANNUALLY FROM AFFLITION

Stammering is an affliction that can be controlled and practically wiped out of existence in a couple of decades by the psychic control of what is a psychic malady.

Society should be kind to the stammerer, ignore his obstruction in speech, and permit other means of communication. If stammering is to be mastered among the 30,000 children affected annually, the psychic dread which aggravates the disability must be removed. How this may be accomplished is here explained.

the payment of fees out of the power of most of the victims to pay, and cures which require a determination the average individual cannot maintain, or an environment which he cannot afford?

Former methods for the treatment of stammering practically constitute a *carte blanche* to run its course. Where breathing and articulatory exercises are employed, the treatment may really intensify the

disorder. It is like pouring oil on a conflagration which it is wished to extinguish. Preventive methods will step on the spark and avoid the conflagration.

To be truly scientific, there must be no hazarding of guesses, no plausible propagation of untenable views, no temporary expedients disguised as cures, no obstruction of the truth for profit; but full consideration must be given the facts, independent of any motive but the benefit of the race, and a steady progress from the good to the better, until the best is attained.

Early Correction Most Promising

Corrective methods should begin with the inception of the disorder. The working theory which best conforms to the facts, first published by Liebman¹ and later fully substantiated in this country, is that in his fright the stammerer consciously obstructs his speech. The rational remedy is to stop the obstruction. Prohibit the stammering. Is that a cure? No; there is no cure for stammering. There never was and, until undesirable memories can be destroyed, there never will be.

The prohibition of stammering is a means, the only means, of correction. It is efficacious at the inception of the disorder, but becomes less so the longer the disorder has run, until in maturity and advanced age supplementary means must be used to obtain anything like satisfactory results. The correction of the chronic stammerer, how-

¹ Liebman, Dr. Albert: Die Psychische Behandlung von Sprachstörungen.

ever, all important as it may be to the individual sufferer, is of zero importance to the race. Early effort where extirpation is possible is where the work should be concentrated.

It may be asked if prevention does not supersede early correction. In the case of most afflictions it does, and to some extent it comes first in the case of stammering. Some such causes as imitation, association, repetition of words, intentional frights, are avoidable. The majority of causes are avoidable.

Psychic Distress the Cause

Anything which induces conscious interference with the newly acquired speech may become an inducing cause. For instance, a little boy eats a lot of green apples and has a convulsion. As he improves his speech does not recover promptly, so he makes a conscious effort to speak. He wants to say: "I ate green apples." He opens his mouth to say, "I," and does not close it; the "I" is abortive. He thinks that his sickness has affected his speech, and makes another conscious effort, this time to say, "Mother." He closes his lips to make the "M" and holds them closed. One has only to make these efforts to find out that they obstruct normal speech. The boy is thrown into a panic, believing that his speech is affected, and he persists in his mistaken efforts. His futile attempts to speak attract censure or other embarrassing attention, which in turn prompts more and stronger efforts which serve only to increase the affliction until it becomes a fixed inhibition. Frights, injuries, exhaustion are of such frequent occurrence among children as to account for the wide prevalence of this distressing malady. It follows that early correction is the principal means for its extirpation.

Correction Is Simple

One important lesson that the history of stammering teaches is our popular misapprehension of science. Science is simple, not complex. Its very purpose is to develop conceptions so simple that they are not generally apprehended. It is true that complex methods at times need to be used in the development of the simple conceptions, and the complexity of methods may be responsible for the popular idea that the incomprehensible is the scientific.

The pursuit of this mistaken idea in the field of stammering has resulted in a cloud of confusion that is unparalleled elsewhere. In its darkness truth is indistinguishable from error, and injury from relief; its pall enshrouds our universities, our philanthropic societies, our government bureaus, and paralyzes effective action,

so that 30,000 children are annually doomed to live their lives in disability and misery on account of this preventable affliction. At the same time we are shouting "child welfare" until the welkin rings.

Fear Causes Trouble to Persist

The view that stammering has its cause in psychic inhibitions is the only one that is tenable. The habit is persisted in because of the speech difficulty itself. The inducing cause passes away. The problem that speech correction has to deal with is the fear of that difficulty. The affliction is intermittent; fluent speech alternates with impeded expression. The fluent speech dissipates the fear; the impeded speech brings it back. It follows that if the impeded speech is not indulged in, fluent speech will gradually remove the fear from memory, and that constitutes recovery.

But how is the stammerer to talk if he declines to stammer? Will he not be mute? By no means. The stammerer is an adept at hiding his difficulty. The public never sees, that is, never recognizes half the stammerers. They wait until a fear is dissipated; they substitute words; they make signs; they write. When the author was stammering severely, he lived for several weeks in a family who never heard him stammer. The malady was cleverly and consistently concealed, but at what a strenuous effort can only be imagined.

Society Makes Men Stammer

Herein lies the sad part of the affliction. The stammerers would all recover if society would allow them to avoid stammering, but society makes them stammer, and so keeps them in their affliction. Parents often force the afflicted child to talk, on the theory that by talking it will talk; the teacher has him recite orally in the embarrassing presence of other pupils; the employer requires dictating, telephoning, and other difficult talking; and so the tendency becomes confirmed into a habit. When will society become as merciful to the stammerer as it is to the blind, the dumb, the deaf, and to other unfortunates?

What constitutes kindness to the stammerer? Relief from speech conventions. Tell the child who begins to stammer that it has no speech requirements; that it is expected to talk only when it is confident of its ability to do so; that it may make signs, or write, or wait, or remain silent; but it is to *decline to stammer*. Similar treatment should be accorded at school, and no speech requirements made. Until they learn to write, little stammerers may recite or read in concert, in which case the inclination to stammer is absent. And then the writing affords another alter-

native for speech. The stammerer is only one in a hundred, so no teacher worthy of the name can object to the little extra work involved in the reading of his written recitation. The pronunciation of foreign languages would have to be eliminated, but the ability to speak any language is not to be sacrificed for the sake of obtaining a little polish in pronunciation.

While the best results are attainable in preventive work, the attention of the public is so centered in the correction of the advanced stammerer that some attention to that branch of the subject is expected. The principle of treatment is the same as that for the child, the difference being that the fluent periods should be much more frequent. Liebman's procedure is safe and sound, but it is capable of much extension.

The patient has not only to combat his fixed habit of interfering with his speech, but he has to contend with an unthinking society which expects him to conform to speech conventions entirely inapplicable to him. He is expected to introduce his friends, to ask for transfers, to purchase the theater tickets, to order the refreshments,—to do innumerable things which are embarrassing to him and, therefore, cause him to stammer. Society should adopt the attitude which leads to the stammerer's recovery instead of his confirmation in the affliction. The patient should be instructed to carry a pad and pencil, and to use them rather than stammer. Few stammerers can purchase a railway ticket without danger of stammering. The circumstances of hurry, witnesses, possibly a curt agent, a definite place to be named—all these make the ticket window a veritable bogie to the stammerer.

The physician should see to it that his stammering patient writes out on a piece of paper what he wants, and has that paper ready to present in case his speech-doubt arises. The very fact that the paper is within reach will often serve to allay his doubt and enable him to speak.

Special Provision for Stammerers

If the patient is in school or college, arrangement should be made for exemption from all required speech and for the maximum opportunity for conversation, preferably with one congenial companion. The physician should impress upon the home circle the reason for the two principles of treatment and the details of application. The stammerer should be provided at the table with individual staples such as salt, pepper, bread, and butter. He should not be asked alternative questions. "Will you have this or that?" The very form of such a question engenders speech-doubt which is almost sure to make him stammer. He

cannot answer it by sign of head and he can seldom answer it by any other sign. Instead of such a question, if it be a choice of tea and coffee, say, "We have both tea and coffee. Will you have tea?" If the answer is negative ask, "Will you have coffee?"

Encourage the Stammerer

The physician has not only these two duties of prohibiting the impeded speech, and promoting the fluent speech, but there is also the necessity of encouraging his patient. A marked improvement may be evident at once; but be not deceived, for any immediate change is only transitory, except that changes for the worse are often of sudden onset.

The panic, or speech-doubt, is reducible only gradually; the patient will invariably expect quick results, so he will almost surely be disappointed, especially if he goes back after an initial uplift. At this stage the physician will find a real labor in keeping his patient in the right path. The affliction renders its victim temperamental, and in such a state he may abandon the treatment unless he has wise council. There is in stammering the opportunity to work miracles. Here is an affliction as old as humanity, world-wide, a serious handicap in an almost essential faculty, and the whole disorder may be wiped out in a couple of decades by a mere change of attitude on the part of society, and the psychic control of what is a psychic malady. The very institutions which are spreading and intensifying it now, primarily the public schools, may be the principal means of abolishing it. Surely modern medicine will not delay to strike the fetters from this great class of slaves who have hitherto cried for justice in vain.

URGES RECONSTRUCTION OF MEDICAL PROFESSION FROM WITHIN

"If the medical profession does not organize as a working body, the majority of doctors will ultimately be drafted into the service of the political state or will be employed by cooperative societies," writes Dr. J. P. Warbasse, of Brooklyn, N. Y., in an article on "Medical Reconstruction," which appears simultaneously in the *Long Island Medical Journal*, the *Medical Review of Reviews*, and the *Western Medical Times*.

He expresses the view that the whole population of every community must be served by the physicians through some plan of group practice, if not one, then another. He says in part:

"A change in the organization of society is now in progress, and medicine like all other callings is destined to participate in the radical reorganization."

"The tendency is toward stateism. Stateism is not the ideal line for the best development of the medical profession."

"As an alternative the medical profession should organ-

ize itself compactly on syndicalistic lines, as a workers' movement.

"As so organized, it may compromise with the political state and develop the guild principle in conjunction with state ownership of medical institutions.

"Or as a syndicalistic organization of workers, it may aim to coordinate its functions with those of cooperative societies of consumers.

"The latter is the ideal plan. But in America it can not yet be consummated because of the still inadequate development of cooperative societies. The growth of cooperation, however, is rapid, and it is conceivable that by the time the medical profession can effect its own reorganization, the people will have developed their cooperative movement to a point at which the two can become coordinated. This is the goal toward which all should look.

"In the meantime the reconstruction of the medical profession should be set on foot as a problem purely of medical organization."

LAW FOR THE DOCTOR

BY LESLIE CHILDS, ATTORNEY AT LAW, INDIANAPOLIS,
INDIANA

*Liability of surgeon for applying extraordinary remedy
in desperate case.*

If, after an operation, the patient's hopes have not been fulfilled, the most likely person in the world to blame is the surgeon; and if in the conduct of the operation or the after treatment there has been even a slight deviation from the usual practice in like cases, this, coupled with a failure to improve, is frequently about all that is required to convince a certain class of patients that they have been grossly abused.

Given a case of this kind a skillful attorney, assisted perhaps by the imagination of his client, will draw a seemingly good complaint upon the absolute minimum of fact and, if this is supported by the slightest evidence, will in most cases get to the jury. Fortunately there is a limit to this sort of thing and, once in a while, the mistaken belief upon which the action was predicated becomes so apparent in the trial that the court is forced to give a peremptory instruction for the defendant doctor. Such a case was that of *Miller vs. Toles*, 183 Mich. 252, the facts being substantially as follows:

The plaintiff, Miller, suffered an injury to his ankle, caused by a fall from a scaffold August 24, 1909. Doctor Tooker was called, pronounced the injury a bad sprain, and prescribed a liniment which was used some three or four weeks. He treated the plaintiff during the fall of 1909 and winter of 1909-10, but without success.

In the spring of 1910 plaintiff consulted Doctor Hagedorn, who took an x-ray of the injured member and prescribed for same, using iodin, which was applied externally. The ankle failed to respond to this treatment so in June, 1910, the plaintiff called Doctor Nottingham who, also, took an x-ray and placed the injured ankle in a plaster cast which was worn about two weeks. After this a second plaster cast was placed on, the same being worn about three weeks. The ankle did not improve.

Plaintiff next consulted Doctor Gordon, who treated the injured member with a hot solution and bandaged it. This brought no relief and on November 19, 1910, Doctor Gordon advised the plaintiff that his case was one which demanded surgical treatment. Doctor Toles, the defendant, was thereupon called into consultation.

After an examination Doctor Toles determined to attempt to save the plaintiff's foot and ankle by the use of the "Murphy Treatment." At the time of this consultation Doctor Gordon expressed the opinion that amputation was necessary. Dr. Toles did not promise anything from the treatment but seemingly gave it as a last resort.

The first injection was given November 20, the second December 3, and the third December 30, 1910. After each injection plaintiff suffered severe pain which lasted from one to three days, requiring the administration of opiates for its relief.

No noticeable improvement followed and on February 14, 1911, it was decided to undertake an exploratory operation. This was done, and the bones on the inside of the ankle were laid bare for examination. The result of this operation, nor the treatment which followed, appears in the report; but the ankle did not improve and on August 7, 1912, about eighteen months after the exploratory operation, the plaintiff's condition became so serious that it was decided to amputate the foot. This was accordingly done.

Later the plaintiff brought an action against Doctor Toles the defendant, charging him with malpractice in the following particulars:

"(1) In administering the injections which he describes as an experimental remedy; (2) in failing to relieve plaintiff's pain after the administration of the several injections; (3) in carelessly and negligently conducting the exploratory operation in such a manner as to cut the muscles and tendons on the inside of the injured ankle, and in failing to support them properly after the operation. * * *"

At the conclusion of the plaintiff's evidence the trial court directed a verdict for the defendant for the reason that there was no evidence tending to show that the treatment given by the defendant in any way caused the loss of plaintiff's foot. From this directed verdict the plaintiff appealed. The Supreme Court, in passing on the record, had this to say:

"* * * It is obvious from an examination of this record that at the time Doctor Toles was called plaintiff's ankle was in an extremely serious condition. It was in such a condition as, in the opinion of his attending physician, demanded amputation. Under these circumstances defendant tried a remedy which appears to have been known and approved by the profession, though perhaps not generally, and which in some instances of diseased joints had achieved remarkable results.

"It is apparent from the testimony of Doctor Gordon, the plaintiff's own witness, that a favorable result from such treatment was scarcely to be expected; at most, it could only be hoped for. Inasmuch as the only alternative at that time was immediate amputation, it would, in our opinion, be a strange application of the law which would hold defendant responsible for its failure. In treating a broken or diseased limb, the implied contract between the surgeon and patient is not to restore it to its natural condition, but to use that degree of diligence and skill which is ordinarily possessed by the average of the members of the profession in similar localities, giving due consideration to the state of the art at the time. * * * stand affirmed."

"We are of the opinion that the circuit judge properly directed a verdict for defendant, and the judgment will stand affirmed."

VOCATIONAL BOARD IN NEW FUNCTION

Representatives from the Federal Board for Vocational Education have been sent to each of the district offices to explain new regulations in the administration of the vocational rehabilitation law. These regulations were revised to meet the requirements of recent changes in the law as amended by Congress. By this recent legislation the benefits of the rehabilitation act are extended to all

*The fifth of a series of articles on "Law for the Doctor," written for MODERN MEDICINE by Leslie Childs.

persons disabled in the service—this, of course, includes those suffering with tuberculosis. The Federal Board is given the entire responsibility of determining the right to and need for vocational training of those persons whose disability prohibits a return to former occupations, and who are unable without training to carry on in a gainful one. The support of the disabled man, with that of his dependents, is entirely the responsibility of the Federal Board during his period of training. The scale of payments made to men in training range from \$80 a month, for the man with no dependents, to \$150 for the married man with six or more children. A schedule of graduated payments is also made for the widower with children and for the man with dependent father and mother.

AMERICAN HOSPITAL CONFERENCE MEETS WITH HOSPITAL ASSOCIATION

On April 21, 1919, a conference to consider the problem now generally designated as "Hospital Standardization" was called in Chicago by Dr. Arthur Dean Bevan, president of the American Medical Association, in accordance with the following resolution adopted at the fifteenth annual conference of the Council on Medical Education, March 3, 1919. The resolution followed the reading and discussion of a paper on this subject presented by Dr. A. R. Warner, president of the American Hospital Association. Dr. Warner presented the resolution; which reads:

"Resolved, That it is the consensus of opinion of the members of this conference that the apparent agreement on the subject of hospital standardization, as expressed in this meeting, should be utilized to expedite progress on this problem. To that end it is the consensus of opinion of this conference that the American Medical Association be asked to take the leadership in formulating a committee, representing all interested factors, which shall give this subject of hospital standardization such consideration and study as is possible, and that the American Medical Association, together with this committee, arrange to call a meeting of all those interested in and affected by hospital standardization at some convenient point and time within the next year."

The conference on April 21st was composed of delegates from national organizations more directly interested in hospital work. After a full day's discussion of the problem at hand and means and possible methods of meeting it, a resolution was adopted that there be formed an organization to be known as the American Hospital Conference to be composed of two representatives each from the following twelve organizations:

- American College of Surgeons.
- American Medical Association.
- American Nurses' Association.
- American Hospital Association.
- Association of American Medical Colleges.
- Federation of State Medical Boards of the United States.
- American Association of Hospital Social Workers.
- Catholic Hospital Association of the United States and Canada.
- American Association of Industrial Physicians and Surgeons.
- Medical Departments of the United States Army, Navy and Public Health Service.

By a second resolution it was decided that there should be an Executive Council of the American Hospital Conference to complete the organization and arrange program for the first meeting. The Council selected by the Conference were the following: Dr. A. R. Warner, president, American Hospital Association, Cleveland, Ohio, chairman; Dr. W. L. Bierring, secretary, Federation of State Medical Boards of the United States, Des Moines, Iowa; Dr. John M. Dodson, acting chairman, Council on Medical Education of the Council on Medical Education of the American Medical Association, Chicago.

It was also decided that the first meeting of the Conference should be held in conjunction with the annual

meeting of the American Hospital Association at Cincinnati in September, 1919.

At the adjournment of the Conference in Chicago, April 21, the leadership of the American Medical Association in the affairs of the American Hospital Conference as provided in the resolution ceased. The Conference became entirely democratic with each constituent association having equal voice in its affairs.

The Executive Council is completing the organization, securing the cooperation of the twelve constituent organizations in the naming of the authorized voting delegates, and working out a program for the Cincinnati meeting in September. At this meeting a permanent organization will be accomplished. At its accomplishment the present Executive Council will automatically cease to exist. The future plans and policies of the American Hospital Conference will be decided by the constituent delegates.

The paper of Dr. Warner which led to the formation of this Conference was published in the *Journal of the American Medical Association*, March 29, 1919, and the full report of the Conference in Chicago, April 21, was compiled and published by the American Medical Association. Copies may be secured either through the office of the American Medical Association in Chicago or through the offices of the American Hospital Association.

The tentative program of the American Hospital Conference at Cincinnati follows.

TENTATIVE PROGRAM OF AMERICAN HOSPITAL CONFERENCE, SEPTEMBER, 1919

The final program including halls assigned for all meetings will be ready for distribution when the conference opens.

TUESDAY, SEPTEMBER 9, 2 P. M. EXECUTIVE SESSION

(Liberty Room, 10th Floor, Gibson Hotel.)
Report of Executive Council, Dr. A. R. Warner, chairman.
General Discussion.

WEDNESDAY, SEPTEMBER 10, 10 A. M. JOINT GENERAL SESSION OF THE AMERICAN HOSPITAL ASSOCIATION AND AMERICAN HOSPITAL CONFERENCE

(Ball Room, Hotel Gibson.)
General Subject, "Hospital Standardization."
"The Organization and Functions of a Hospital," speaker to be announced.
"Medical Education Through the Visiting Staff and Interns," Dr. John M. Dodson, Dean, Rush Medical College, Chicago.
"Better Professional Work Through a Better Staff and Better Records," Mr. John G. Bowman, Executive Secretary, American College of Surgeons.

WEDNESDAY, SEPTEMBER 10, 2 P. M. JOINT GENERAL SESSION OF THE AMERICAN HOSPITAL ASSOCIATION AND AMERICAN HOSPITAL CONFERENCE

(Ball Room, Gibson Hotel.)
The Hospital's Service to Humanity, The Rev. Charles R. Moulinier S.J., president, Catholic Hospital Association of the United States and Canada.
Discussion, opened by Miss Edna G. Henry, president, American Association of Hospital Social Workers.
"The Education of a Nurse," speaker to be announced.
"The Trustees and Layman Viewpoint," speaker to be announced.

THURSDAY, SEPTEMBER 11, 10 A. M. EXECUTIVE SESSION

(Liberty Room, 10th floor, Hotel Gibson.)
General discussion of organization and work.

THURSDAY, SEPTEMBER 11, 2 P. M. EXECUTIVE SESSION

(Liberty Room, 10th floor, Hotel Gibson.)
General discussion of policy and procedure.
Adjournment.

GRIP CAUSES MORE DEATHS THAN WAR IN ITALY IN 1918

According to statistics published in the *Secola*, of Rome, there were in Italy 800,000 deaths during 1918 caused by grip, or about 60 per cent more than the total deaths caused by the war. The same paper estimates the deaths by grip throughout the world were double the deaths caused by the war.

THE MONTH IN MEDICINE

Survey of Current Medical Literature with Editorial Comment

WALTER W. HAMBURGER, M. D., Editor

ONE ASPECT OF SYPHILIS AS A COMMUNITY PROBLEM

UNDER the above title Newcomer, Richardson, Ashbrook, and Lewis¹ present their experiences with the establishment of a syphilis clinic at the University of Pennsylvania. In his introduction Lewis comments on the studies of Davis, showing that 10 per cent of all persons presenting themselves to a general hospital for treatment are there either because of syphilis, or because their illness is complicated with a co-existent syphilis. Lewis further makes the plea that to eradicate syphilis the combined efforts of all specialists concerned—educators, physicians, police, and sociologists—must be utilized.

Newcomer discusses the organization and management of the clinic. A social service worker follows up the patients, and sees that the instructions of the doctor are carried out. Saturday afternoon is devoted to the administration of salvarsan for which the patient pays a moderate fee of from three to four dollars. A further discussion of technic, results, effect on the Wassermann reaction, etc., may be consulted by those interested in such details. The discussion of the Wassermann interpretation is particularly worth while.

Richardson presents the studies of twelve syphilitic women who were pregnant at the time or soon became pregnant, and he concludes that "the condition of the mother improved with treatment, though several still showed signs of syphilis—with positive Wassermann—even after the birth of apparently normal children."

From the standpoint of the economic results to the patient from systematic treatment in a special clinic, the results obtained in twelve patients who were followed up are interesting. "A table has been prepared which picks out specifically twelve patients whose earning capacities are given, whose immediate loss of time due to the

incapacitation in consequence of the disease, and the cost of whose treatment, and the time, and amount of money saved through the agency of the salvarsan clinic are also given. It will be seen that for these twelve patients, treatment cost them \$81, saved them \$1,080 in earning capacity, and a year of time. If the clinic were a charity, which at present it is not, a charity so expended as to bring 1,000 per cent on investment would be a very profitable one indeed."

Lewis summarizes as follows: "Our experience as presented in the preceding sections shows that it is practicable for any well organized general hospital to establish a clinic for the treatment of syphilis, without great expense to the institution, and to the certain advantage of the community it serves. . . . It being assumed that such clinical facilities as those described have been made available in adequate amount, the attack on syphilis as a community problem should make, as a measure of the first importance, systematic effort to secure treatment at the earliest possible moment for the infected."

Comment.—The establishment of specialized out-patient clinics seems to be a sign of the times. The following are already represented: Tuberculosis, infant welfare, mental hygiene, cardiac and industrial clinics, and this most recent addition, the syphilis clinic. Their effectiveness in the concentration of effort and thought to more exact and systematic diagnosis and treatment in the special conditions represented has been demonstrated. One cannot help voicing a note of warning that too widespread and detailed specialization may prove harmful. As in this clinic, further specialized clinics should wait until the needs of the community demands their establishment.

EDITOR.

I hold every man a debtor to his profession; from which they as men of course do seek to receive countenance and profit, as ought they of duty to endeavour themselves by way of amends to be a help and ornament thereunto.—Bacon.

SERIOUS CHARACTER OF INFLUENZA EPIDEMICS

IN MARCH, 1890, the Edinburgh Medico-Chirurgical Society devoted an entire meeting to the discussion of the influenza epidemic then prevailing. The serious character of the pandemic of 1918-19 was such as to make it the subject of the May, 1919, meeting and a series of able studies, fully discussed, brought out the salient features of the situation. We quote from the *Edinburgh Medical Journal* a summary of the discussions:

"Dunlop¹ estimates that in Scotland the disease has caused 20,000 deaths, and these mostly in the age periods 15 to 45. Probably most of those who remember the epidemics of the early nineties will agree with Russell² that the malady then was essentially the same as that which has recently played such havoc. Unfortunately, it cannot be said that, in the quarter century which has elapsed, our knowledge of influenza has undergone any very material advance. We are still quite in the dark as to the cause of its sudden pandemic spread, and as to why it has once again taken on so serious a character.

"It is tempting to blame for these the conditions which have obtained throughout Europe since 1914, and to suppose, with James³, that the nations have trenched unduly on their reserves of strength in the effort to victory, but in the face of the virulence of the epidemic in Africa and India, where such a factor could scarcely be operative, it seems almost impossible to escape the conclusion that exalted virulence of the infective agent has played a larger part. So far, bacteriology has not conclusively shown the nature of the infection. It is clear that in cases of influenza or influenzal pneumonia three organisms, or groups of organisms, are more or less constantly present--the bacillus of Pfeiffer, the pneumococcus, and the streptococcus. The outstanding fact which arises from Logan's work on the bacteriology of the Edinburgh cases is the multiplicity of types and sub-groups of the organisms present. Even Pfeiffer's bacillus is not one, but comprises a group of organisms. Bacteriological data such as Doctor Logan gives militate strongly against the likelihood of an effective anti-serum being produced in the immediate future.

"The relation of the Pfeiffer to the Bordet Gengou bacillus of whooping-cough was referred to by Dr. Ford Robertson⁴ and although it raises a side issue the point is a suggestive one. These two organisms resemble each other very closely from a bacteriological standpoint; it is sometimes most difficult to decide, especially in an adult who has had whooping-cough as a child, whether an irritating, paroxysmal, spasmodic cough is "post-influenzal" or true whooping-cough. Certainly the resemblance between whooping-cough with an ill developed whoop and some cases of influenzal catarrh is very great.

5. Logan, W. R.: The Bacteriology of the Influenza Epidemics of 1918-1919 (based on an interim report to the Medical Research Committee, from the Royal College of Physicians, Edinburgh). *Edinburgh Med. Jour.*, 1919, n. s. xxiii, No. 1, 54.

6. Robertson, Ford: Discussion, *Edinburgh Med. Jour.*, 1919, n. s. xxiii, No. 1, 53.

7. Porter, Frederick: Certain Points in Treatment. *Edinburgh Med. Jour.*, 1919, n. s. xxiii, No. 1, 59.

"The outstanding question at present with regard to the etiology of influenza—the part played by filter-passing organisms—was barely touched on in the discussion. . . . Another point raised, which has wider implications than the etiology of influenza, is the possible effect of the deficiency in vitamines of such butter substitutes as the vegetable fats, which were so largely used as butter substitutes during the war. The study of these vitamines has hardly begun, yet already it foreshadows a great advance in the scientific application of dietetics.

"So far as the treatment of influenza is concerned, no definite proof of the efficacy of vaccines was adduced. Doctor Porter's experience with phenol certainly appears to warrant a more extended trial of that remedy. For the rest, it does not appear that any advance has been made in practical therapeutics; particularly if pneumonia develops, most will agree with James that the problem is heart-breaking. Apart from the direct sequelae, the more important of the remoter consequences of influenza are seen in the lighting up of tuberculosis, and in the production of maladies of the nervous system. Acute tuberculosis is not very infrequently seen after influenza, yet it is interesting that the epidemic did not seem to bear hardly on the inmates of sanatoria, nor, indeed, is there any great tendency for the disease to spread in well ventilated wards. It would seem from this, that the infection, like that of measles, does not spread very far from the person affected, and also that fresh air is one of the best prophylactics.

"The nervous complications of influenza have long been recognized as common and serious. The late Sir Thomas Clouston used to speak of it as a disease which lowered the nerve tone of a community, as was shown by an increase in mental disease after the epidemics of 1899-94, and his successor, Doctor Robertson, has the same tale to tell. What, if any, relation subsists between influenza and lethargic encephalitis is not known; the coincidence of the two diseases in epidemic form is remarkable, and demands elucidation. The possibility that both may be due to filter-passers, the occurrence of meningeal and lethargic symptoms in many cases of influenza, and the undoubtedly prevalence during the past year of sudden deaths of young adults with acute cerebral symptoms are curious facts. Toxic psychoses, too, have unquestionably been far from rare during the recent epidemics, taking the form of mania, confusion, or stupor. It is too soon, yet, to attempt to collate recent work on influenza, but the disease has been the subject of such intense study from all sides that we feel justified in believing that many aspects of the disease which are still obscure will soon be unveiled to us."

JOURNAL OF INDUSTRIAL HYGIENE

The August issue of the *Journal of Industrial Hygiene* offers the following original articles:

FACTORY INSPECTION AND FACTORY INSPECTORS. By George M. Price, M.D., director of the Joint Board of Sanitary Control in the Cloth, Suit and Skirt Industries, New York City.

HERINA IN INDUSTRY. By Charles A. Laufer, M.D., medical director, Relief Department, Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa.

THE OCCURRENCE, COURSE AND PREVENTION OF CHRONIC MANGANESE POISONING. By David L. Edsall, M.D., Jackson professor of clinical medicine, Harvard Medical School; consultant in industrial hygiene, United States Public Health Service; chief of industrial clinic, Massachusetts General Hospital; F. P. Willard, M.D.; and Cecil K. Krinker, M.D., associate professor of applied physiology, Harvard Medical School.

PUBLIC HEALTH NURSING AND INDUSTRIAL HYGIENE. By Mary Beard, R.N., director, Instructive District Nursing Association, Boston; president, National Organization for Public Health Nursing.

INDUSTRIAL POISONING BY COMPOUNDS OF THE AROMATIC SERIES. By Alice Hamilton, M.D., special investigator, United States Bureau of Labor Statistics; assistant professor of industrial medicine, Harvard Medical School.

REPEATED BLOOD PRESSURE READINGS AS A CONSERVATION MEASURE

BY L. M. BOWES, M.D., CHICAGO

EXPERIENCE has taught us that if all employees who have passed the age of forty-five were examined at regular intervals the number of accidents would be greatly reduced. Neither would so many serious wrecks occur with great loss of life and the injury of many people because some engineer, who should have been pensioned or discharged some time before, had died of cardiac disease or had become dizzy or unconscious while at the throttle of an engine and ran the train into an open switch, or into some passenger train. Neither would elderly men so frequently fall unconscious at some unexpected time and injure themselves.

Such a case came to the attention of the writer recently in a man who in leaving his place of business passed through a crowd of men and was picked up in an unconscious condition several blocks away by a policeman who had seen him fall. He sustained a severe cut on his head and was sent to a hospital where he was given first aid. This man knew nothing of his movements from the time he passed through the group of fellow employees and thought that, as he had expressed his views on the temperance question rather freely, some wet sympathizer had taken offence and slugged him. Examination revealed that he had fibromyocarditis and advanced arteriosclerosis; if he overexerted or remained in a stooping position very long he would become dizzy. By changing the nature of his work he was able to retain a position with the firm without danger to himself or others.

It is true that since the liability acts went into effect placing directly upon the employer the responsibility for injuries and deaths which occur because of some negligence or inefficiency the number has been greatly lessened. Such examinations would greatly decrease the number of injuries and deaths, and the number of preventable diseases due to insanitary conditions also would be diminished, thus promoting the conservation of human life to a great extent.

To assist in making these examinations there is no measure which is more exact or more valuable than blood pressure observations. This is recognized by nearly all of the life insurance companies and they require the systolic and diastolic readings in the reports of all risks. It is granted that in many instances the blood pressure obser-

vations alone do not help us any but they should be made in all routine examinations because when studied with other objective symptoms their value is greatly increased. On the other hand, increased pressure frequently indicates some serious disease even when there are no subjective or objective symptoms present, the person apparently enjoying robust health.

Magnuson¹ claimed that he "insisted on blood pressure examinations to nip in the bud the chance of getting any man into service who was liable under quick strain or violent exercise to get a stroke of apoplexy, to fall dead at his work, to be apparently killed in the service, when, as a matter of fact, it was a pathological process in his own body which killed him."

In making blood pressure observations both the systolic and diastolic pressures must always be taken because quite frequently the diastolic or systolic pressures are more important than the systolic alone.

Arteriosclerosis

In arteriosclerosis more or less difficulty is experienced in analyzing the blood pressure findings and arriving at the proper conclusion because the blood pressure changes are not regular and uniform, and it is frequently difficult to eliminate the elements in blood pressure which are due to associated conditions. The influence of arteriosclerosis upon the blood pressure also depends upon the degree of involvement and the distribution of the lesion; some have very little if any effect, while others, notably lesions of the splanchnics, the cerebral, and coronary arteries, and the aorta may have marked influence. The diastolic pressure is usually increased in these lesions but not in proportion to the systolic pressure which causes an increase in the pulse pressure.

Inequality of the pressure of the two sides of the body is frequent in arteriosclerosis; therefore, simultaneous observations on the two arms should be made, especially in those showing indications of premature senility. As the process of arteriosclerosis continues a sufficient degree of hypertrophy of the heart takes place to maintain perfect compensation and both the systolic and diastolic pressures increase; but if the cardiac muscle should fail to compensate through myofi-

¹ Magnuson, P. B.: *Railway Surg. Jour.*, November, 1913.

brosis the pressures will fall, and thus there may be very high or normal blood pressures in arteriosclerosis.

Intracranial Pressure

In cerebral hemorrhage, thrombosis, depressed skull fractures, rapidly growing cerebral tumors, or any other cause of increased intracranial pressure there is hypertension. High systolic with high diastolic pressure indicates increased intracranial pressure or chronic nephritis; and a sustained hypertension both of the systolic and diastolic pressures indicates cerebral hemorrhage, while hypotension indicates cerebral embolism.

Hypertension

No individual who has a persistent hypertension together with a morning headache, vertigo, numbness, or tingling of the hands or feet should be placed in any position where the lives of others are endangered, because these symptoms indicate the presence of nephritis or arteriosclerosis, or cerebral hemorrhage may occur upon sudden strain or severe exertion.

In all cases of hypertension a very careful search should be made for the cause so that it may be removed. In many cases no cause can be found and if the heart, blood vessels, and kidneys are normal, undue importance should not be attached to these cases. Neither is it wise to give high blood pressure undue weight to many individuals because they will become alarmed and will watch their blood pressure constantly, even exaggerating all aches and pains and connecting them with the high blood pressure. This tendency to introspection is carefully to be avoided. These cases must be watched, however, more closely than normal cases.

Chronic Nephritis

High systolic and diastolic pressures are found regularly in chronic interstitial nephritis. The pulse pressure is proportionately increased. Associated conditions, such as arteriosclerosis, chronic toxemia, and myocarditis, may modify the blood pressure findings. If the element of nephritis predominates, the systolic pressure greatly increases and it is in these lesions that systolic pressures of 250, 300, and even higher may be observed. The diastolic pressure is always increased and, roughly speaking, in proportion to the severity of the nephritis. This disproportionate increase of the diastolic pressure is considered the most characteristic change in blood pressure in this lesion. Hypertrophy of the left ventricle must occur to maintain this pressure.

In this condition as in all instances of hypertension, when the limit of hypertrophy has been

reached, when the reserve power of the heart is exhausted and myocardial degeneration has developed, the increase in pressure ceases and later, as the process of degeneration progresses, a decline in pressure occurs. The decline in systolic pressure is greater than that of the diastolic, causing a low pulse pressure.

In uremia the systolic and diastolic pressures increase in correspondence to the severity of the symptoms, becoming very high in the more severe conditions.

The blood pressure may or may not be high in chronic parenchymatous nephritis. When present its association with the other findings is important, but its absence does not rule out this disease.

The Anginas

The anginas are accompanied with hypertension. Some of the highest blood pressures are observed with angina of the abdominal blood vessels. *Angina abdominalis* occurs much more frequently than is generally supposed and in nearly every instance which has come to our attention it has been diagnosed as acute indigestion, gallstone, or renal colic. In all of these cases the nitrites gave immediate relief. In every instance where nitroglycerin was administered under the tongue complete relief was obtained promptly.

It is believed that atheroma is more commonly found in the gastric and mesenteric arteries than it is in the coronary arteries. *Angina abdominalis* is observed more frequently than *angina pectoris* in the aged.

Cardiac Diseases

Blood pressure observations are important in cardiac diseases. A sustained high systolic with a low diastolic pressure is usually associated with aortic regurgitation. In all cases of sustained hypertension the importance lies in the ability of the cardiac muscle to carry the extra load.

The great question is: how long will the cardiac muscle sustain this high pressure? In this condition a lowering pressure indicates a failing heart. When the limit of the cardiac reserve power has been reached, the diastolic pressure falls with but not as rapidly as the systolic pressure, causing a decreased pulse pressure. Uncomplicated myocarditis may show no marked change on the blood pressure for some time, but when the reserve power of the heart is exhausted the natural result is a fall of both the systolic and diastolic pressures. There may be a greater decrease in the diastolic pressure with an increased pulse pressure.

Occasionally in aortic regurgitation the dia-

systolic pressure can not be obtained because a sound is heard until all pressure in the armlet is removed. The systolic and diastolic pressures are regularly lowered in chronic valvular disease with decompensation.

A low diastolic pressure may also be present in cases of chronic rheumatism, acute enteritis, carcinoma, tuberculosis, and the anemias.

Chronic Toxemia

In chronic toxemia of intestinal origin the systolic and diastolic pressures are usually lowered, but if associated with chronic nephritis and possible arteriosclerosis these pressures may be raised.

The degree of increase in blood pressure due to chronic toxemia of intestinal origin may be ascertained by removing the toxemia by proper dietetic treatment and subtracting the subsequent blood pressure readings from those first taken.

Chronic tobacco poisoning may be a cause of hypertension both of the systolic and diastolic pressures; the fall of the systolic is greater than that of the diastolic pressure which results in a low pulse pressure. Later, the effect of tobacco seems to lose this influence, because in aged men who have been habitual smokers for fifty years or longer observations made before and after smoking give the same results. Also in our observations the pressures remained the same whether the men smoked or had not smoked during a prolonged period. These variations in the blood pressure seem to be proportionate to the susceptibility of the individual.

Conclusions

Although blood pressure is a comparatively new subject and there are many difficulties in the interpretation of the clinical significance of variations in the systolic, diastolic, and pulse pressures we believe that:

1. The importance of making observations of the systolic and diastolic pressures of all employees more than forty-five years of age, at stated intervals of six months, can not be overestimated.

2. If this is conscientiously done there will result great conservation of human life.

3. By such observations with corrective measures the earning capacity of many individuals will be greatly increased.

4. By this means the number of injured and the number of those in ill health as a result of poor working conditions will be decreased.

5. Better relations will be established between the employers and employees, thus promoting the interests of both.

NEW HAVEN HOSPITAL BEGINS COURSE IN DIETARY STUDIES

An elaborate course of training in dietary studies for student dietitians has been arranged for the coming year at the New Haven Hospital, New Haven, Conn. The work covers the theoretical phases of the subject, the administrative duties of the dietitian in hospitals or other institutions, and the practical application of principles in laboratory, kitchen, serving room, or office.

The close relationship of dietary problems to medicine and the dietetics of particular classes of diseases are emphasized. The following outline of the training course is published by courtesy of the New Haven Hospital:

OUTLINE FOR TRAINING OF STUDENT DIETITIANS THEORETICAL WORK.

Pathological physiology—Dept. of Experimental Medicine, Yale University School of Medicine.
Pathology of nutrition—Yale University School of Medicine.
Nutrition of Growth—Lafayette B. Mendel, Sheffield Scientific School, Yale University.

Dietetics of Infancy and Childhood—Dept. of Pediatrics, Yale University School of Medicine.

Dietetics of Pregnancy—Dept. of Obstetrics, Yale University School of Medicine.

Dietetics of Pre- and Post-operative Cases—Dept. of Surgery, Yale University School of Medicine.

Dietetics of Special Diseases—Dept. of Medicine, Yale University School of Medicine.

Acute infectious diseases.

Gastro-enteric.

Cardio-vascular-renal.

Metabolic.

Cutaneous.

Physiological Seminar—Lafayette B. Mendel, Sheffield Scientific School, Yale University.

Dietary Administration—E. M. Geraghty.

1. General principles of hospital dietetics.

2. General principles to be observed in buying dairy products.

3. General principles to be observed in buying meats.

4. General principles to be observed in buying staples.

5. General principles to be observed in buying canned goods.

6. Contracts.

7. Equipment.

Manufacture.

Value.

Placement.

Care.

8. Factors influencing efficiency of employees.

PRACTICAL WORK

DIET LABORATORY (2 months)

Dietetics of special diseases.

1. Planning, preparing and serving of food for patients requiring dietary treatment.

2. Computing and recording value of food intake of above mentioned patients.

3. Preparing feedings for infants.

KITCHEN (one month)

Supervision of requisitioning of food supplies.

Supervision of care and storage of food supplies.

Supervision of preparation and distribution of food.

Supervision of care and utilization of left-overs.

Supervision of cleaning of kitchen.

Supervision of employees in kitchen.

SERVING-ROOM (one month)

Inventory of dishes and silver.

Supervision of care of same.

Supervision of service of food.

Supervision of cleaning of rooms connected with serving-room.

Supervision of care of stationary equipment.

Organization of work of waitresses and pantry workers.

OFFICE (one month)

Dietary studies.

Menu making.

Cost accounting.

Preparation of outline for teaching nurses dietetics.

Teaching nurses dietetics.

Outlining equipment for dietary department of 250-bed hospital.

Routine office work.

While here, do some problem in hospital dietetics; nature of problem to be determined by need of individual.

Visits to other hospitals, followed by report on dietary departments.

Visit to food inspection laboratory at state experiment station.

Study of milk industry in New Haven.

Study of market conditions in New Haven.

Study of ice cream industry in New Haven.

Army Casualties 297,147, July 2nd

Total casualties in the American Expeditionary Forces, including all corrections and alterations published to July 2, are given in an official report as 297,147. This was a net increase of 1,565 over the preceding report on June 25. Battle deaths increased 321 to 50,150 and total deaths 400 to 78,917. The wounded aggregated 216,309.

BOOKS OF THE MONTH

Comment on Current Medical and Health Literature and Announcements of New Books

CLINICAL MICROSCOPY AND CHEMISTRY. By F. A. McJunkin, M.A., M.D., professor of pathology in the Marquette University School of Medicine. Formerly assistant in the pathological laboratory in the Boston City Hospital.*

It is difficult to believe that there is need or room for yet another manual on these subjects. The one under review is adequate for the guidance of the laboratory workers of a hospital which cannot afford to employ specialists in the various departments. It is exceptional in that it treats of the management side of a hospital laboratory in some detail. The pathological section is much fuller than the biochemical. In the latter we note the usual confusion in dealing with hydrogen ion solution. On page 101 the statement is made that "A normal acid solution contains one gram of hydrogen ions per liter." This would mean that a liter of normal acetic acid would have the same hydrogen ion concentration as a liter of normal hydrochloric acid, which is absurd. There is no mention of the valuable and extensively used method of fractional gastric analysis. About half of the illustrations are neither necessary nor instructive. The others are excellent.

THE ADVENTURE OF LIFE. By Robert W. McKenna, M.A., M.D., author of *The Adventure of Death*.†

To the average man the things he learns remain an unrelated mass until they become an integral part of him by means of some poignant personal experience. Others, through concentrated thought and a desire for mastery, are able to comprehend the unity and inseparability of the facts of life. To a few men it is given to understand all that comes within their ken; they are able to sense all known relations, and to surmise all potentialities. These last are the interpreters for the masses, the men with vision who lead us on.

Such a thesis as "The Adventure of Life" could be handled only by a man with vision, for the subject is life itself that "can never be explained in terms of sheer materialism, nor reduced to mere chemical equations, nor expressed entirely in the language of the physical or physiological laboratory." The book is not scientific, it is not philosophic; yet it is written by a scientist and a philosopher; by a seer, it might be claimed; certainly by a versatile and ripe thinker who impresses upon the most casual reader the "wonder and harmony of life and the complete interdependence between all forms of life."

In the chapters on the origin of life a preconceiving Mind is a logical necessity to explain the ages of preparation of the physical world for the achievement of forms of life more adaptable and more capable of progress. Nor is this conception of the directing Mind incompatible

with science. The Mind responsible for the chemical affinities and molecular combinations which resulted in the appearance of the first living protoplasmic cell was also responsible for endowing the protoplasm with the power of adapting itself to its environment until at last man stood erect upon the earth.

As man dominated the physical world, so his intelligence made further conquests. His rapid progress is attributable to the fact that the mind culture of one era passes on to the next. Anatomical and morphological changes may require a million years for their development; social and cultural changes may be impressed upon the individual and established in a race in a life time. Herein lies the hope of the race. However soul-destroying or body-warping the environment, a change in condition, plenty of sunshine and pure air; above all, education and sufficient incentive, and the race is rejuvenated,—the purity of her stock protected; all the more blame to society for the vicarious sufferers from intolerable social conditions that should be remedied.

Man's freedom is attained as right conditions are achieved. The motives, man's soul, are the outgrowth of the energizing effect of ideals aimed at; the pangs he suffers from his neglect to obey Nature's laws; the lessons of universal need to be learned from sharing the common suffering of the race; the triumph of shouldering his share of pain until perfect knowledge enables him to lay it down.

Harmonizing all, comes the love whose real basis is sex-instinct that insures the continuity of the race and incidentally entails obligations which result in that social and religious institution, the family, and necessitate work, that saving and satisfactory means of using up the "reserve-stuff" of energy. "The honesty of workmanship is the acid-test of character."

If by means of it all a man achieves faith, and is able without fear to regard death as an interesting and necessary part of the adventure of life, his destiny is fulfilled.

APPLIED BACTERIOLOGY. Studies and Reviews of some Present-Day Problems for the Laboratory Worker, the Clinician, and the Administrator. Edited by C. H. Browning. Contributors: C. H. Browning, W. Gilmour, T. J. Mackie, S. Russ, R. Gulbransen, J. F. Smith, and L. H. D. Thornton.‡

This little volume consists of a collection of twelve papers, many of them previously published. It deals with some of the newer methods of isolation by enrichment, of the typhoid, paratyphoid and colon organisms from the stools, etc., and their identification culturally and serologically. Isolation of members of the diphtheria group is discussed with special reference to the reognition of pathogenic members.

There is an interesting paper on the selective action of

Insurance Against Invisible Dangers

The demand for greater efficiency along economic and industrial lines carries with it the need for better sanitary conditions wherever groups of people are employed.

Tiled wash-rooms in factories and other institutions help greatly in meeting this necessity.

The use of Tile in all comfort stations, public baths, swimming pools, hospitals, etc., not only serves to stimulate the general morale, by reason of its cleanliness and beauty, but provides that **insurance against invisible dangers** which is desired as protection for the individual and the general public.

We offer a service of real benefit to those who are in position to use Tile in any way.

AUSTRALASIA STERLING & CO.
Modern Chambers, 317 Collins Street, Melbourne.

SUBSCRIPTION

Domestic postage, \$3.00. Foreign postage, \$3.50 (15 shillings). Single copies (regular), 25 cents.

Domestic rates include United States, Cuba, Mexico, Porto Rico, Canal Zone, Hawaii, and Philippines.

SUBSCRIPTIONS.—Subscriptions may begin at any time. Volumes begin January except in the case of Volume I, which consists of the numbers issued during 1919 (May to December, inclusive).

REMITTANCES.—Remittances for subscriptions should be made by check, draft, post office or express money order, or registered letter. Make all checks and money orders payable to MODERN MEDICINE.

CHANGE OF ADDRESS. Notice of change of subscriber's address should give both old and new addresses. Notice should reach us fifteen days in advance of date of publication.

COMMUNICATIONS.—When communications relate to more than one subject (manuscript, reprints, subscriptions, news items, etc.), correspondents will confer favor by writing on a separate sheet for each subject, thereby insuring more prompt attention.

ADVERTISEMENTS.—The advertising pages of MODERN MEDICINE are available for announcements of anything of interest and service to those engaged in the treatment and care of the sick and especially to those who are devoting their efforts to organized medical and health work. Advertisements of secret remedies and other objectionable announcements will not be accepted. The supervision of the Editors is extended to the advertising columns, in which only approved products and reliable manufacturers will be represented.

CLOSING OF FORMS.—Advertising forms close on the 10th for the issue of the following month. Ample time should be allowed for composition of advertisements and the sending and return of proofs.

ADVERTISING RATES.—Advertising rates will be sent on request.

CONTRIBUTIONS.—Original articles on any problems of practical interest to our readers are respectfully solicited from those who can write authoritatively on current problems in social medicine, hygiene and medical service in industry, public health and allied subjects. Articles are accepted for publication with the understanding that they are contributed solely to MODERN MEDICINE.

ILLUSTRATIONS.—Such half-tones and zinc etchings as in the judgment of the Editors are necessary to illustrate articles will be furnished when photographs, drawings, or ink tracings are supplied by the author.

NEWS MATTER.—Our readers are requested to send in items of news, and also marked copies of newspapers containing matters of interest. We shall be glad to know the name of the sender in every instance.

BOOKS OF THE MONTH

(Continued from Page 458)

antiseptics which will be of great help to those intending research along these lines, or meeting the problems of isolation by "enrichment."

The paper dealing with the possibility of selective isolation by the employment of ultra violet radiation is very suggestive, as is, also, the discussion of the chemistry of anti-body reactions.

Special reference should be made of the very excellent table of references to the bibliography accompanying many of the papers.

The book is attractively bound, is printed in readable type on good paper and is well indexed. It will be welcomed by the laboratory worker and bacteriologist; but, with the exception of the very practical chapter on tetanus, it is difficult to see of what use it would be to the clinician.

Quaker Oats vs. Beef Steak

Measured by calories—the energy unit—Quaker Oats is twice as nutritious as round steak.

Quaker Oats yields 1810 calories per pound—round steak yields 890.

In carbohydrates they are about alike. In fat the difference is not great. In protein, oats yield 16.1 per cent, against 19 per cent for steak.

In mineral content oats excel steak by about three to one.

Steak is about 68 per cent water and refuse—Quaker Oats only 7.3 per cent. So steak will cost from 8 to 10 times Quaker Oats for the same calory value.

Quaker Oats costs 5 cents per 1,000 calories. Meats, on the average, cost 50 cents or more.

Quaker Oats

Extra - Flavory Flakes

Quaker Oats holds supreme place among oat foods the world over. That fact is due to its flavor. It is flaked from queen grains only—just the rich, plump, flavorful oats. We get but ten pounds from a bushel.

It offers all this extra flavor without extra price, so it is the ideal oat food for a child.

The Quaker Oats Company

Recent Ohio legislation in regard to tuberculosis hospitals includes a bill permitting a county which holds membership in a tuberculosis district to provide additional local facilities at its own expense if the district hospital fails to provide adequate accommodations; a bill authorizing a county in a hospital district to withdraw from membership and sell its interest to any other county in the district if the action is approved by the state department of health; and a bill authorizing a county in which a municipal tuberculosis hospital district is located to establish a county hospital or to buy or lease the existing municipal hospital. Eight inter-county hospital districts have been organized up to date in the state, and five districts, including 23 counties, have hospitals in operation.

Quick Relief

from the painful symptoms of Gonorrhoea will be appreciated by your patients. Gonosan promptly allays the severe pains, the burning and priapism.

In Urethritis and Cystitis

GONOSAN

has proven highly effective in limiting the course and extent of the inflammation. Its comparative freedom from irritating effects upon stomach and kidneys emphasizes its value as the best coadjutor of local treatment.

Vetoes Pennsylvania Mosquito Act

On the ground that the measure recently adopted by the Legislature of the state of Pennsylvania will rid the state of the breeding places which produce mosquitoes, Governor Sproul has vetoed the act.

LAW SANCTIONS MEDICAL TREATMENT OF DRUG ADDICTS IN NEW YORK

In response to a request by the health commissioner of the city of New York for a ruling on the question of whether the health department has legal power to use the existing machinery of the department in the treatment of drug addicts, an affirmative reply has been furnished by Corporation Council William P. Burr. The opinion supports the contentions of Dr. Royal S. Copeland that the city should make use of the municipal farm at Warwick, N. Y., for the care of afflicted subjects. The counsel also cites the data gathered by Federal officials showing the alarming extent of the illicit traffic in drugs, and commends the recommendations of Dr. Walter R. Herrick, commissioner of the state department of narcotic drug control, for the suppression of illegal manufacture and sales of narcotics. The opinion further declares that the city may under existing laws accept the offer of the Rockefeller War Demonstration Hospital, to aid in the solution of the problem and in the care of drug addicts.

FORMS CHICAGO HOUSING ASSOCIATION

A promise of early improvement of housing standards in the city of Chicago by the development of residence communities for industrial workers, where homes may be built at cost with long-time payment privileges, comes with the formation of the Chicago Housing Association.

Through the instrumentality of Benjamin J. Rosenthal the association has been organized with the sole object of providing homes at cost, upon easy monthly payments, to purchasers who would be unable to meet the commercial obligations that usually go with the building of homes. The project has been financed by Chicago citizens and a tract of property set aside for the use of builders. The lives of the buyers will be insured to safeguard against death, and other arrangements are planned in case of unavoidable defaults.

An effort will be made to meet the modern thought on homes for industrial workers. Sunshine will be provided for each room in the house, as well as attractive architecture and surroundings. Each community will be developed along lines of artistic unity and a community house will be erected.

The board of directors of the association includes J. Ogden Armour, Judge Bernard P. Barasa, Col. Abel Davis, George W. Dixon, Dorr E. Felt, Charles W. Folds, A. Volney Foster, William Grace, Herman H. Hettler, D. F. Kelly, Albert D. Lasker, Miss Minnie F. Low, Harry H. Merrick, Simon O'Donnell, Benjamin J. Rosenthal, Julius F. Smetanka, John Paul Stafford, Frederic W. Upham, Miss Harriet E. Vittum, Charles H. Wacker, Thomas E. Wilson, Harry A. Wheeler, William Wrigley, Jr.

The officers of the association are the following: Herman H. Hettler, president; William Grace, vice president; M. E. Greenebaum, treasurer; A. Volney Foster, secretary.

A department of occupational therapy has been instituted by the Rochester Tuberculosis Association for the benefit of patients ill in their homes but able to do a little work without overtaxing their strength.

The Value of Sleep is by no means limited to the repairing of bodily wastes—

NEARLY every employer of labor now realizes that the life and habits of employees has a great deal to do with their individual adaptability and efficiency.

Science is not alone in emphasizing the importance of sound, restful sleep. Commonsense observation, time, labor and individual efficiency tests under many and varied conditions, prove the need of *enough* sleep for every person—and, that without it, no worker can perform his or her full share of service in the realm of business.

Civic, industrial, health and welfare workers interested in bettering living, housing and working conditions in their various communities can render no greater service to their people than that of investigating the subject of sleep.

Give and encourage workers—everybody in fact—to live, sleep and work under modern, sani-

tary conditions and a new generation of bright-eyed, alert and efficient people will result.

Simmons National Publicity has always been devoted, directly or indirectly, to this all-important subject of sleep. As the largest makers of metal beds in the world, it is our desire to supplement the efforts of physicians, public health officials, civic and industrial welfare workers by distributing helpful and instructive data on the subject.

Thousands of leaflets and booklets have been supplied without cost to those engaged in this work and more of them are ready to send to those interested and anxious to make their efforts productive of better living and sleeping conditions.

A letter addressed to our main office at Kenosha will bring full particulars regarding the co-operative service.

KENOSHA, WISCONSIN

Accurate Diagnosis First

No industrial hospital is complete without the most modern facilities for diagnosis. They must be ever ready for the immediate attention a patient's case demands.

Diagnosis directs the course of treatment and can only be accomplished by the most advanced and approved aids.

For just such attention by the industrial or municipal physician our

MODERN DIAGNOSTIC OUTFIT

is arranged. It contains all the instruments most generally needed in urgent cases.

Others will be substituted if desired. Stamp "E. S. I. CO." is guaranty of our manufacture.

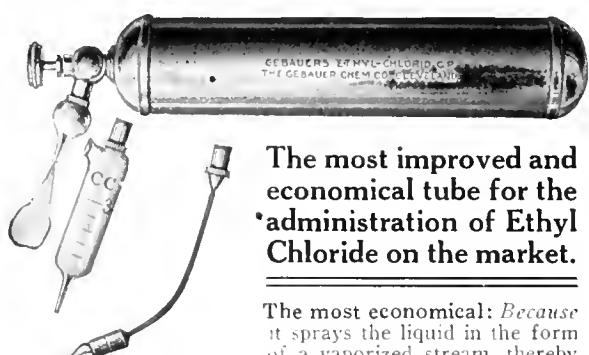

This outfit weighs but 4½ pounds. All instruments can be operated by our battery with adapter or upon direct or alternating current by means of our controller.

Illustrated catalogue sent upon request.

Electro Surgical Instrument Co.

Rehabilitation Hospitals Train 25,600

Returns of the General Hospitals where disabled soldiers, sailors, and marines are receiving restorative treatment and vocational training contained the names of 25,600 officers and enlisted men of the army on July 1. Most of these men will be in the hospitals from two to four months.

INFERIOR CLINICAL THERMOMETERS BEAR MISLEADING CERTIFICATES

Commerce Reports, July 26, 1919, prints the following items which are taken from *Technical News Bulletin* No. 27 of the Bureau of Standards, Department of Commerce:

Heat Value of Fuels

"Tests of the heating values of fuels have become of great commercial importance, as practically all coal sold on large contracts is paid for on the basis of the heating value found in the tests conducted by or for the purchaser. The instrument used for carrying out this test is the bomb calorimeter, which comprises a strong, steel cartridge or capsule with removable cover, adapted to contain a small charge (about 1-30 ounce) of coal. The bomb is tightly closed and oxygen is introduced under high pressure. It is then put into a calorimeter, the coal ignited electrically, the heat generated being absorbed by the water. The quantity of heat liberated in the combustion of the fuel is then calculated from the rise in temperature of the water. Important aid has been given in the standardization of the testing of coal for calorific power by the issuance by the Bureau of Standards samples of materials of accurately known heat values which afford a simple, precise, and convenient means by which the user of the calorimeter may check up the accuracy of his own determination."

Misleading Clinical Thermometer Certificates

"The clinical thermometer is the fundamental measuring instrument of the physician. Such thermometers, when purchased by the government, are subjected to rigid tests, but those sold to physicians and the public are usually only tested by their manufacturers. Often such thermometers are sold with a misleading certificate, so worded as to give the impression that the instrument has been tested by the Bureau of Standards. As such instruments are nearly always of the cheapest and least reliable grade, a great deal of harm is done in this way. Letters from the bureau warning purchasers against buying such thermometers have been published in numerous medical and pharmaceutical journals. The recently formed American Association of Clinical Thermometer Manufacturers has taken a great deal of interest in suppressing these misleading certificates, and in cooperating with the bureau to this end in the preparation of a new form of certificate. It is the intention so to word this certificate that it can only be used when the instrument which it accompanies has actually been tested by the bureau. If this joint action fails to produce the desired result, congressional legislation will become necessary along the lines recently followed in the state of Massachusetts."

The California Tuberculosis Association has opened a Tuberculosis Preventorium in Marin County, California, where a small group of children from six to fourteen years old, below par physically and likely to become tuberculous, will be housed, receiving medical attention, attending an open-air school, and being given remedial gymnastics.

"DOWNTOWN DYSPEPSIA"

THREE'S a type of indigestion," says a well known New York physician, "that is so common to the men and women who work downtown, that I call it "*downtown dyspepsia*." It is caused by rapid eating under high nervous tension. The food is hardly chewed at all, only slightly softened or mixed with saliva, and enters a stomach which because of the constant activity of the brain, is not prepared to digest it properly.

The individual sufferer, even from the mildest form is far from being a well person. He feels badly most of the time and is inclined to pessimism.

Treatment has usually been unsatisfactory, for it is next to impossible to get these people to change their habits of eating.

But while doing "my bit" in France last year, I learned some facts concerning the effects of chewing gum in promoting the flow of saliva and relaxing nervous tension, which gave me a valuable cue to the treatment of this "*downtown dyspepsia*."

It is evident that the chief details in the causation of this form of indigestion are salivary insufficiency and constant mental concentration.

So for over six months I have been recommending my dyspeptic patients to chew Adams Pepsin Chewing Gum regularly for fifteen to twenty minutes after every meal."

SCHOOL FOR HOSPITAL SUPERINTENDENTS

In order that superintendents of hospitals and physicians who wish to extend their professional studies to cover the problems of hospital administration may have opportunity to enter upon a course of training adapted to their needs, the College of Medicine of the University of Cincinnati has opened a department of hospital administration as a division of the Department of Industrial Medicine and Public Health. Dr. Arthur C. Bachmeyer, superintendent of the Cincinnati General Hospital, will have charge of the new department. The dearth of trained executives for hospital administrative work has been an important factor in the minds of the University authorities in the creation of the department.

COUNTY PROPOSES HEALTH SURVEY

On the advice of Dr. Ray L. Wilbur, San Mateo County, Cal., has decided to have a survey of the health commissions of the county made before the plans for the new county hospital are drawn. Dr. William Palmer Lucas of the Medical School of the University of California, who has recently returned from Europe, where he was decorated by the King of Belgium in recognition of his work in organizing the care of French and Belgian children, has been selected for this task. The study is to include the needs of San Mateo County from a health point of view, with a careful examination of health and sanitary conditions now existing, and of the facilities now existing in hospitals, clinics, welfare associations, etc., now available for meeting these conditions; the careful examination of the county's methods of handling housing, sanitation, and other health questions; and meetings of county sanitary inspectors, county physicians, board of supervisors, social service commission and welfare and public health commission, for the discussion of the various points for consideration.

FORMS NATIONAL INFORMATION BUREAU FROM INVESTIGATING BODY

The National Information Bureau with offices at 1 Madison avenue, New York City, has been reorganized from the National Investigation Bureau. The purposes to be accomplished are to protect the contributing public and to assist in the conservation and proper distribution of the charitable resources of the country during the reconstruction period.

The three definite purposes of the Bureau are:

1. The establishment of reasonable standards of administration and work for national social and philanthropic agencies and the endorsement of agencies which meet these standards.

2. The protection of the public from imposition.

3. The assisting, so far as may be possible, of national agencies in their efforts to adapt their programs and their work to each other and to the communities in which they are engaged.

The officers of the Bureau are: Gustavus D. Pope, president; Paul L. Feiss, vice-president and treasurer; Paul D. Cravath, second vice-president; Allen T. Burns, secretary; Barry C. Smith, director.

The Board of Directors of the Bureau are as follows: C. M. Bookman, Allen T. Burns, H. S. Braucher, Paul D. Cravath, Robert W. De Forest, Paul L. Feiss, Frederick A. Geier, Porter R. Lee, Owen R. Lovejoy, Samuel Mather, J. Horace McFarland, Francis R. McLean, William J. Norton, Gustavus D. Pope, Lawson Purdy, Dr. Rush Rhees, J. D. Robinson, John R. Shillady, and Willoughby Walling.

SCIENTIFIC—EFFICIENT ECONOMICAL *Pain Relieving Methods*

You appreciate the value of sunlight as a therapeutic agency; you know about the pure white rays, the violet rays and the ruby screen. The Sterling Therapeutic Lamp combines all these agencies in an efficient and economical manner.

STERLING THERAPEUTIC LAMP "The Light That Heals"

Has proved one of the most efficient methods of relieving pain; its effect is soothing and analgesic; its rays are germicidal. The warm, soothing, soft rays penetrate and vitalize every cell and tissue, new cell growth is stimulated; the body is refreshed and vitalized.

In rheumatism, neuralgia, neuritis, lumbago, in nervous conditions and a score of other symptoms and diseases, including skin and scalp disease, the Sterling Therapeutic Lamp is invaluable for the relief from pain, inflammation and for corrective purposes.

With stand it is ideally adapted for additional use as a spot light for operations and examinations.

Widely used in sanitariums, physicians' offices and hospitals; special sizes are adapted for the use of patients under the supervision and direction of the family physician.

Write for our interesting Illustrated Booklet showing the various sizes and uses of the Sterling Therapeutic Lamp.

A. M. A. STUDIES HEALTH INSURANCE

The report of the Council on Health and Public Instruction, wherein there has been embodied an outline of the policies and work of the American Medical Association for the coming year, which the Council recommended to the House of Delegates at the recent Atlantic City convention, says this of social or health insurance:

"There is to-day no subject in the field of social medicine that deserves and will require more careful, exhaustive, dispassionate, and unprejudiced study than social insurance, or that will, whatever the final conclusions, demand greater tact, diplomacy, and good judgment in practical handling."

It is predicted by the Council that, within a year, social insurance will be a vital issue in a number of states. This being true, the Council urges that the active interest of physicians is demanded for properly appraising the plan and directing public policy in the matter of health insurance.

The Council states the problem as it appears in the United States, apart from the data and experience of other countries, in the following paragraphs:

"There is in this country a certain amount of illness among those whose gross annual income is below an amount that will permit them to bear the expense of such disabling and incapacitating illness without being seriously and perhaps permanently handicapped or crippled thereby.

"Such disabling and crippling illness being conceded, if the individual is not able to carry it alone, then the burden must be lightened in some way. This can be done by increasing the income of the individual and thus elevating his economic status to a point where he can carry his own burden; by reducing the amount of sickness through the enlarging and improving of state public health activities; or by distributing the cost of existing disabling illness among the three parties at present responsible, namely, the individual, the industry and the state, so as to relieve the individual of from 60 to 80 per cent of his burden. A fourth possible procedure, not exactly to be regarded as a remedy, but as a possible line of action, is the *laissezfaire* principle of permitting existing conditions to continue and remedy themselves if possible without interference. The first of these proposed plans might be called the economic remedy; the second, the state public health remedy; the third is social insurance, and the fourth is no remedy at all.

"In this discussion, many questions arise that cannot be answered with our present knowledge. What is the amount of sickness incurred by the average wage earner in the course of the year? How much of a burden is this to him and to his family, through loss of wages, medical attendance, nursing and care, incapacity or reduced productivity consequent on illness, nonemployment resulting from illness, etc.?

"What is the average amount which the individual loses each year through sickness? How much of this loss is due to preventable disease which can be eliminated by increased state health activities and by the better organization of health agencies? What is the minimum annual income that will enable the individual to carry successfully the burden of his own disability? How many American families have an income below this minimum?

"If the first remedy proposed, that of increasing the annual income to a point where each individual can carry his own burdens, seems best, how is this desired object to be accomplished? If the second remedy is adopted, namely, increase of governmental health activities to a point where preventable disease is reduced to a minimum, how large a burden of nonpreventable disease will remain? Will not the increase of governmental health activities to such a point produce just as marked and radical a change in the medical profession as the proposed health insurance? What effect will the plan proposed have on the work and income of physicians? Without providing for the unemployed and the indigent, who would still, as in England, have to be cared for under poor laws and charity organizations, would not the increased profes-

Pituitary Extract

THE clinical use of Pituitary Extract is two-fold: (1) *Obstetrical*, in cases of inertia or delayed labor when not due to mechanical causes; (2) *Surgical*, to prevent and relieve post-operative "gas pains"; to increase diuresis; to prevent surgical shock; and to prevent and control hemorrhage.

Pituitary Extract—*Lederle* is physiologically standardized according to the method of Roth (U. S. Hygienic Laboratory Bulletin No. 100). It is adjusted to conform to *Liquor Hypophysis, U. S. P. IX* and is not in any other strength.

According to Speath (U. S. Hygienic Laboratory Bulletin No. 115):

"Since in clinical practice it is a simple matter to vary dosage, it seems reasonable not to raise the strength of the U. S. P. IX requirement but to inject, if necessary, as much as 2 cubic centimeters of pituitary solution in order to produce the required effect."

Dosage of Pituitary Extract—*Lederle*

Obstetrical, $\frac{1}{2}$ to 1 cc

Surgical, 1 to 2 cc

A. M. A. STUDIES HEALTH INSURANCE

(Continued from Page 32)

sional income from cases of the insured, whom the doctor to-day takes care of for little or nothing, increase the average professional income, provided the compensation for professional services could be properly determined? Would not this increase amount to more than the loss due to lowered rates? If the proposed social insurance can be shown to be necessary and to be the best solution of the problem involved, can the medical profession as a class successfully oppose it simply on the ground that it may interfere with or disturb our professional income and livelihood?"

Dr. Alexander Lambert presented the report of the Committee on Insurance, which is accompanied by data on the cost of sickness and the average family expenditure, the average amount of sickness, distribution of sickness, the extent of present medical care among wage earners, wages, and the cost of living, and the interest of the medical profession in sickness insurance. Following are quoted several brief excerpts from the material gathered by the committee:

"Over and above the loss in wages must be reckoned the cost of medical care for employees and their families. Certain fee schedules of the medical, dental, and nursing professions and for hospitals were collected by the Pennsylvania Health Insurance Commission. Considering the professional skill and the responsibility involved, many of the fees are most moderate. They are given to show what employees in this state must pay, under present conditions, to receive medical care on an independent full-cost basis. They cannot be taken to represent the actual charges made but represent merely the standard minimum fee for regular professional services, exclusive attention from specialists. . . .

"Naturally, many employees cannot fail to pay these charges. As a result, we have physicians and hospitals giving service free, or at reduced rates, a host of medical or semi-medical charities, and throngs at the free dispensaries, as well as numerous cases of entire failure to receive medical care where it is sadly needed. . . .

"Any attempt to aid in the solution of the sickness problem must have as its goal the complete restoration of the sick man or woman to health. To this end, immediate and adequate medical, surgical, and institutional care must be made available, and the contingency of suspension of earnings during the periods necessary for recovery must be met. This is but justice to the disabled person, to industry, and to the community at large."

In conclusion the following comment is offered by the committee: "The responsibility, therefore, is threefold—communal, industrial and individual. But the burden to-day is almost entirely individual. The community has accepted part of its liability and endeavored, by sanitation, preventive medicine and hospitalization, to improve the situation. Industry has, until now, evaded its entire responsibility and liability. The individual still bears the brunt of the burden and the cost of sickness as a personal calamity. The community and industry have begun to realize and accept their share of the liability. We have in the past received from southern and southeastern Europe enormous numbers of hardy, vigorous laborers and industrial workers. We have used them lavishly, and their labor extravagantly. We have neither wisely harbored their energy nor salvaged the damaged. We have recklessly used this labor as if the supply were unlimited. We have indeed treated it as we dealt with our forests and our mines. We have been mining out our labor and burning it up. Now the war is over, hundreds of thousands of these peoples are returning to their former

(Continued from Page 34)

homes, not to return here. This country is facing a scarcity of labor, and must care for it and salvage it, when injured, as never before.

"The remedy for this situation lies economically in a redistribution of costs, not of adding new costs, but rearranging the present method of expending the costs already being expended. Large numbers of wage-earners, probably a majority of them, now spend each week enough money on funeral insurance, that they may be sure of a decent burial, which would equal or more than equal their share of any just sickness insurance scheme to give them sick benefits, maternity and adequate medical care, and a \$100 funeral benefit. Improved medical care must come from more cooperative and less purely individualistic care from the medical profession. Free choice of physician by patient, and present relation of patient to physician, and just and assured remuneration for work done by the physician can easily be assured to the physicians under an insurance plan.

"Preventive and curative medicine can equally be more fully developed with free play for individual development of physicians. The alternatives offered by the funeral insurance companies are a further development of preventive medicine, state care of the sick by salaried physicians, and leaving the profits of funeral insurance undisturbed."

BIRTHS AND INFANT MORTALITY

The preliminary report of the Bureau of the Census for 1917 contains a statistical summary of births and infant mortality. The data is published in *Public Health Reports*, June 27, 1919, and follows in part:

"In the birth-registration area of the United States 1,353,792 infants were born alive in 1917, representing a birth rate of 24.6 per 1,000 of population. The total number of deaths in the same area was 776,222, or 14.1 per 1,000. The births exceeded the deaths by 74.4 per cent. For every State in the registration area, for practically all the cities, and for nearly all the counties, the births exceeded the deaths, in most cases by considerable proportions. The mortality rate for infants under 1 year of age averaged 93.8 per 1,000 living births.

"The birth-registration area, established in 1915, has grown rapidly. It comprised, in 1917, the six New England States, Indiana, Kansas, Kentucky, Maryland, Michigan, Minnesota, New York, North Carolina, Ohio, Pennsylvania, Utah, Virginia, Washington, Wisconsin, and the District of Columbia, and had an estimated population of 55,000,000, or about 53 per cent of the estimated total population of the United States in that year.

Comparison with 1916

"The birth rate for the entire birth-registration area fell below that for 1916 by two-tenths of 1 per 1,000 population; but the death rate was less by six-tenths of 1 per 1,000 than in 1916. Thus, the excess of the birth rate over the death rate for 1917, which amounted to 10.5 per 1,000, was somewhat greater than the corresponding excess for 1916, 10.1 per 1,000, although it fell slightly below that for 1915, 10.9 per 1,000. If the birth and death rates prevailing in any one of these three years were to remain unchanged, and if no migration were to take place to or from the area to which they relate, the population of the area would increase at the rate of slightly more than 1 per cent per annum, or a little more

BIRTHS AND INFANT MORTALITY

(Continued from Page 36)

than 10 per cent in a decade. This would be about half the rate—21 per cent—by which the entire population of the United States increased between 1900 and 1910.

White and Colored

"Of the total number of births reported, 1,280,288, or 24.5 per 1,000, were of white infants, and 73,504, or 25.8 per 1,000, were of colored infants. The death rates for the two elements of the population were 13.7 and 22.5 per 1,000, respectively.

Infant Mortality

"The infant mortality rate—that is, the number of deaths of infants under 1 year of age per 1,000 born alive—throughout the birth-registration area as a whole was 93.8 in 1917, as against 101 in 1916 and 100 in 1915. This is equivalent to saying that in 1915 and 1916 of every 10 infants born alive 1 died before reaching the age of 1 year, whereas in 1917 the corresponding ratio was a trifle more than 1 in 11. Among the 20 States these rates ranged from 67.4 for Minnesota to 119.9 for Maryland; and for the white population separately the lowest and the highest rates were, respectively, 66.3 for Washington and 109.5 for New Hampshire.

"The infant mortality rates vary greatly for the two sexes and for the various nationalities. The rate for male infants in 1917, 103.7 per 1,000 living births, was nearly 25 per cent greater than that for female infants, which was only 83.3. When the comparison is made on the basis of race or nationality of mother a minimum of 66.2 per 1,000 births is shown for infants with mothers born in Denmark, Norway, and Sweden, and a maximum of 172.6 for infants with mothers born in Poland, while for Negro children the rate was 148.6.

Plural Births

"The reports from the registration area show the birth of 14,394 pairs of twins and 155 sets of triplets in 1917—in all, 29,253 infants, or a little more than 2 per cent of the total number born.

Number of Children Per Family

"The reports for 1,241,722 of the births occurring in 1917 contained information as to number of child in order of birth. Of these reports, 339,042 were for the first child born to the mother, 264,044 for the second child, 191,528 for the third, 134,331 for the fourth, and 95,931 for the fifth. In the remaining 216,846 cases, or 17.5 per cent of the entire number for which information upon this point was obtained, the total number of children borne by the mother was 6 or more; in 37,914 cases it was 10 or more; in 1,600 cases, 15 or more; in 56 cases, 20 or more; and in 1 case, that of a colored woman, the birth of a twenty-fifth child was reported.

"The total number of children borne by the mothers who gave birth to these 1,241,722 infants in 1917, in whose cases data were available as to previous births, was 4,093,908. The reports for 1,194,621 of the births occurring in 1917 contained information as to the entire number of children borne by the mothers and still living, and gave a total of 3,443,466, or an average of very nearly 3 living children in each family in which a birth took place in 1917."

If any misanthrope were to put, in my presence, the question, "Why were we born?" I should make reply, "To make an effort."—Charles Dickens.

Cafeterias and Rest Rooms *are* Common Sense Health Insurance

The physical and mental well-being of employes are important factors in the efficiency of every industry.

Faulty nutrition is recognized as a detrimental condition for the satisfactory progress of school children as well as preventing 100 per cent service from the employe.

Properly conducted cafeterias have proved their worth in bringing the individual up to par in both industries and schools.

Rest and club rooms, considered essential by many employers, add that element of good will necessary for the complete co-operation of the employe.

The experts of Albert Pick & Company have made an exhaustive study of these and similar conditions and the results of this survey will be gladly forwarded to anyone interested.

Write for our special literature as follows:

Book G10—Lunch Room Book—containing complete data on industrial lunch room installations.

Book G40—Rest Room Book—The whole story of the rest room.

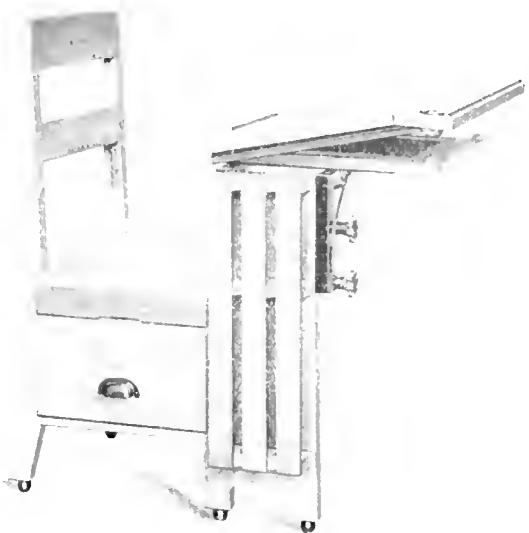

Book G60—Employment Betterment—The story of what industrial welfare work means in actual results.

Basic Principles Embodied in the Construction and Design of the New York Study Chair

First A movable seat and desk in one unit

Second—A seat modeled to the normal shape of the thighs and buttocks, allowing thereby the pelvis to rest on the normal weight-bearing surface of the tubera ischii, and thus avoiding forward slipping of the pelvis with its forward rim tilting upward and consequent distortion of the spine.

Third A seat adjustable to height

Fourth A back so formed as to allow the occupant to maintain the torso in the normal erect position

Fifth—A movable back support, convex forward, that will maintain the normal forward lumbar curve and compel an erect position of the entire spine.

Sixth—A back of proper height with a top cross bar to prevent round shoulders

Seventh A desk that can be easily adjusted to any desired position, height or angle for drawing, reading or writing

Eighth A back, seat and desk, so correlated as to give a correct and yet comfortable "set-up" to the occupant when at work

THE MATERNAL MORTALITY OF CHILD-BIRTH AND THE TEACHING OF MIDWIFERY*

One of the problems which will require earnest consideration by the new Minister of Health is the present position of the teaching of midwifery to medical students and midwives. Obstetrics medicine is essentially the branch of medicine in which prevention can and should play a very large part. There is to all intents and purposes no cure for puerperal fever, and yet it is a disease which is almost entirely preventable. That it is not more often prevented is one of the anomalies, and, indeed, scandals of the present-day practice of medicine. As Mr. Victor Bonney points out in his instructive and important paper read before the Obstetrical Section of the Royal Society of Medicine (see *Lancet*, vol. exvi, No. 4993), by far the commonest cause of death in childbirth is puerperal sepsis. Even as recently as 1915 over 1,200 women lost their lives from this cause in England and Wales alone, and yet the occurrence of a case of septicemia in that year, apart from military surgery, in a surgical ward of a well-conducted hospital would have been regarded as an event indicating some very serious defect in the management of the case. By the exact practice of asepsis or antisepsis surgeons are able to undertake operations in any part of the body in the confident expectation that there will be no septic infection, and yet at the present day puerperal fever, which is, of course, only surgical septicemia occurring in the parturient woman, claims a very large number of victims and has a death-rate which has altered relatively very little during the last seventy years. It can be proved readily that the safest thing that can happen to a woman in childbirth is that she should deliver herself without any artificial aid, and it may be said without fear of contradiction that if in all cases of normal labor the patient delivered herself without the assistance of either a doctor or a midwife a large number of lives would be saved each year. This is a hard saying, but one which we maintain is true; in other words, the great majority of women who die from puerperal sepsis are infected by their attendants.

That in proper surroundings and with proper aseptic or antiseptic precautions puerperal fever is preventable is proved by the experience of lying-in hospitals; why, then, is it not prevented in private practice? The answer is to be found in Mr. Bonney's statement that "not much more than a bowl of antiseptic lotion stands between the practice of the present day and that of the 'sixties.' But a bowl of antiseptic lotion is not Listerism." It is promising to note that the teaching of midwifery and its defects is now engaging the attention of those who instruct in that subject, and there are many among the younger teachers who recognize the changes that must be brought about in the near future if any real improvement is to be effected. The apathy of the medical profession and of the public in this matter has been very marked; many writers have drawn attention to the prevalence of puerperal infection, the resulting morbidity and mortality of child-birth, and the grave consequences they entail, but the medical profession has been content to go on in the old way, and the teaching of our medical schools has done little or nothing to remedy a state of things in which, while septic infection following a surgical operation is regarded as a rare accident to be rigorously investigated, sepsis following a confinement is looked upon almost as a necessary evil in a certain proportion of the cases. We

Stanolind Surgical Wax

Reg. U. S. Pat. Off.

For use in the hot wax treatment of burns, surgical wounds and similar lesions.

It is unapproached in purity and may be applied without incorporating with it any therapeutic agent.

Many advanced workers advocate its use in that manner.

However, surgeons may use it as a base for any of the published formulas, and may be assured that it is the purest and best wax that modern science can produce.

It conforms to the requirements of the Council of Pharmacy and Chemistry of the American Medical Association.

Stanolind Petrolatum

In Five Grades

"Superla White" is pure, pearly white, all pigmentation being removed by thorough and repeated filtering.

"Ivory White," not so white as Superla, but compares favorably with grades usually sold as white petrolatum.

"Onyx," well suited as a base for white ointments, where absolute purity of color is not necessary.

"Topaz" (a clear topaz bronze) has no counterpart—lighter than amber—darker than cream.

"Amber" compares in color with the commercial grades sold as extra amber—somewhat lighter than the ordinary petrolatums put up under this grade name.

MATERNAL MORTALITY OF CHILDBIRTH

(Continued from page 401)

may not be inclined to agree with all Mr. Bonney's statements or conclusions, but we cannot deny that he has laid bare the real cause of the evil and that he has propounded the appropriate remedy. Some of his critics may think it right to make fun of his dislike of the anus and his proposal to paint the perineum with one or other of the colored aniline antiseptics, but we are glad to think that he has had the courage not only to expose the faults which are associated with present-day midwifery practice but also to lay down the only sound principles upon which the needed remedies can be based.

The present methods of teaching midwifery to medical students are extremely faulty, and if the conditions in London are not comparable in all details to those at certain other educational centers, none the less they call for urgent reform. The provision of sufficient accommodation in properly equipped (and properly staffed) lying-in hospitals, to which any woman who desires can obtain admission, is most pressing—it is one of the first problems which the new Ministry of Health must consider; while the education of the public in the urgency and importance of these matters calls for the cooperation of every member of the medical profession, and is a part of the solution of the problem in which everyone can take his or her share. The defective training of the student is mainly due to the fact that the major part of the teaching is done by registrars and residents who are themselves in the position of learners and often have had but little experience. While in medicine and surgery most of the practical work is done by members of the honorary staff of the hospital in surroundings which lend themselves to proper and efficient teaching, in midwifery practical teaching of this kind is not done at all or is carried out by junior men, sometimes in the lying-in ward of a general hospital, of which there are only three in London, or more often in the extern maternity department, among the entirely unsuitable surroundings which are portrayed so vividly by Mr. Bonney. There is only one remedy—the teaching of midwifery must be done in the future in properly equipped lying-in hospitals under the same favorable conditions which obtain in the case of medicine and surgery. If the plan of providing whole-time properly paid teachers is to obtain in the latter two subjects, then the same must apply to midwifery, and in this way only, in view of the special conditions surrounding the practical training, will it be possible for the student to obtain his teaching in midwifery from teachers of equal experience and standing to those who are engaged in teaching him medicine and surgery. This will entail the provision of spacious central institutions properly equipped and officered, sufficiently large to enable all the students in London, for example, to be trained in them, and furnished with all the laboratory facilities necessary, not only for the carrying out of the pathological investigations necessitated by the treatment of the patients, but also for the carrying on of efficient research. In such surroundings only will it be possible for the student to be taught on the lines laid down by Mr. Bonney, with which we are in complete agreement.

Women on English Research Board

The Industrial Fatigue Research Board of England has been completed by the addition of the names of Miss Winifred C. Cullis, D.Sc., head of the department of physiology at the London School of Medicine for Women, and Miss Mona Wilson, National Health Insurance Commissioner since 1912.

NOTES AND COMMENT

THE AMERICAN PUBLIC HEALTH ASSOCIATION

THE AMERICAN Public Health Association will hold its forty-seventh annual meeting in New Orleans, October 27-30, 1919. The announcement of this meeting grows increasingly in interest each year as the expansion of the organization continues and as the subject matter with which it deals is recognized as more vital to national welfare.

There was a time when the persons attending the American Public Health Association consisted almost entirely of public health officials or men engaged directly in the work of public health. The concept of public health has broadened to such an extent that it is now a gathering of all types of professional people engaged in modern medicine. Men in public life and in private enterprises too are giving thought to the subject in its various aspects.

The program of the forthcoming session is broad in its scope and practical in its bearings upon existing health problems. It offers much to the health officer, to the practising physician, the industrial hygienist, and to the sociologist, besides being of direct concern to men of affairs who guide the Ship of State.

Public health problems have become our first problems, and the American Public Health Association is the general clearing house for the discussion and formulation of the principles and plans in the public health field. Its program should receive the most earnest attention of all those who believe that national safety and security depend in the ultimate upon the vitality of the people.

THE RED CROSS PEACE PROGRAM BROAD IN SCOPE

IN ANNOUNCING the peace program of the Red Cross Dr. Livingston Farrand, chairman of the American Red Cross Central Committee, expressed briefly the broad scope of the program and set forth a clear vision of the future. "No organization," he said, "can speak dogmatically. We can see only the next step ahead, and we do not intend to plunge blindly, hoping to land on our feet." Of the health program, he said:

"The greatest contributing factor in disturbing the happiness of mankind reduces in the last instance to questions of physical wellbeing—to problems of health and disease. A large portion of the disease of the world is preventable disease. Nations have been coming to a point where they realize that fact, and they are turning—the whole world is turning to organizations of every kind for help in the prevention of preventable disease. There has been no hesitation in reaching the conclusion that the great problem of the world is the problem of disease."

"This is not talk; it is fact. We are now seeing that these things that have been known for years by science—by medical science—are being realized by the people. And the question the people are everywhere asking is 'What are we to do?' They are looking for help; they are looking for guidance; and they naturally look to the organizations that are built upon such a basis and have been guided in such a way as to beget confidence."

Pointing out the fact that the Federal Government has no constitutional authority to work out the problem of health, and that beginnings are

only just being made in a few of the advanced states in the provision for adequate health machinery, he showed the necessity for stimulating by private agencies an appreciation of the opportunity and a realization of what can be accomplished. He emphasized the necessity of coordination of the various movements for public health, pointing out that "all of these movements are single different sides of the great problem of the improvement of health and the prevention of disease and misery."

"Furthermore," he said, "we have here an organization that represents every one of the national interests, that knows no party whatever, that knows no creed whatever, that has attached to it every type of man, woman, and child in the United States, and we propose to put this energy behind a great movement for coordinating and bringing these interests so far as possible together."

Lastly, he emphasized the necessity of a nursing program and indicates the line along which the Red Cross will work. "The biggest activity in this field which the Red Cross has already undertaken," he said, "is a great nursing program. The entire modern health movement depends upon the adequate development of the visiting nurse. We are doing the most important thing in taking that step first."

The unfolding of the program of the Red Cross as set forth by Doctor Farrand will be watched with keen interest and appreciative sympathy for the ends in view and for the Red Cross as the agency in securing them.

RECRUITING PUBLIC HEALTH NURSES

ONE of the most interesting by-products of the war upheaval has been the tremendous impetus given to the public health nursing movement.

The public has learned what it is to be without nurses, the lesson being pointed by the catastrophe of the influenza epidemic, when every available nurse was invaluable and when the pressing necessity of cooperative utilization of nursing service became obvious to everyone. As a result, the public health nurse is deservedly popular and the demand for this new type of public servant greatly exceeds the supply. It is probable that this condition will continue for some time to come, as the present available educational opportunities are not sufficient to cope with the task of preparing the very large number of new recruits needed for this field. It is estimated that there is now a demand for from seven to ten times as many public health nurses as are available.

Laws making the employment of public health nurses from public funds mandatory or permissive are now on the statute books of the following states: Arizona, Idaho, Iowa, Kansas, Kentucky, Minnesota, Nebraska, New York, North Dakota, Ohio, Oregon, South Dakota, and Wisconsin. In addition, industrial managers in increasing numbers are alive to the relation of physical health to the efficiency of the worker and are clamoring for adequately trained nurses. The informal bureaus of occupation maintained by the National Organization for Public Health Nursing and the Red Cross have far more applications than they can care for.

Here once more we have an example of how easily a wholesome and most welcome social innovation can outrun its power to organize itself. Before the war the National Organization for Public Health Nursing and the Town and Country Nursing Service of the Red Cross, were endeavoring to demonstrate the value of public health nursing in terms of the welfare of the community served. It cannot be said that the need for such propaganda has passed; indeed a large part of the effort of the Red Cross would appear to be directed toward completing the education of tardy communities as to the indispensability of the public health nurse. But it is certainly true that the demand already created far outruns the supply.

In recognition of this fact, the National Organization for Public Health Nursing is devoting a large proportion of its resources to educational and recruiting activities. It is endeavoring both to direct a growing percentage of student nurses into the public health field and to recruit from the high schools, normal schools, and colleges, more high grade material for this new profession whose future potentiality may be judged by its vitality now, when the movement is only in its infancy.

There is a further complicating factor. In many states and indeed in many counties, we have the spectacle of a variety of both specialized and general nursing services, doing work in the same field and exhibiting neither uniformity of standards as to personnel and service nor a sufficiently positive disposition to coordinate their efforts. There is, therefore, the greatest possible need of standardizing and coordinating agencies. This has been from the beginning the chief task of the National Organization for Public Health Nursing, but the movement has far outgrown the capacity of any private organization for supervision and standardization. What is needed is the consolidation of the public health nursing movement with the normal processes of democratic government. In other words, the only agency that can really

handle the public health nursing situation is the state. The National Organization for Public Health Nursing has clearly recognized this fact as evidenced by the emphasis given to legislative work on its 1919-1920 program. Three suggested bills have been prepared of which the third, which provides for a division or bureau of public health nursing in the state department of health with a supervisor of public health nursing serving as one of its officials, is the most interesting and indeed the one which the National Organization for Public Health Nursing will urge wherever possible. The other two suggested bills, which are extremely general in their provisions, and, incidentally, the more practical on that account, provide simply for the employment of public health nurses from county funds. One of the bills is mandatory, the other is permissive.

In determining the type of legislation to be advocated, the National Organization will be guided entirely by the conditions encountered in the different localities. It will in all cases work in thorough accord with the public and private agencies concerned.—ELLA PHILLIPS CRANDALL.

THE NATIONAL SAFETY COUNCIL

THE National Safety Council which held its Eighth Annual Safety Congress in Cleveland, October 1-4, 1919, is an organization of broad scope and unique power in the field of industrial betterment. Organized only seven years ago, it has attained a large membership and very real influence in the solution of important industrial problems. In its beginning the Council was concerned almost entirely with the subjects of accident prevention and safety devices. It was very soon seen, however, that safety in industry was far wider in its scope than the prevention of accidents. On the one hand it was seen that pre-existing conditions were the cause of many accidents, and that disabilities aggravated or infected on account of being neglected were even more serious. On the other hand it was seen that sickness in the industry was a cause for much labor turnover and for much inefficiency among employees. The result of this enlarged view was that the work of the Council broadened into a consideration of all of these factors which condition the well-being of the workers in industry. A separate health service section was organized and the subject of health in industry was brought into many of the sectional and general meetings.

The program for this year shows more than fifteen noteworthy papers in six different sections on the distinct subject of health. MODERN MEDICINE will publish the important papers on health

problems in the November issue. Subjects of Physical Examination, Lead Poisoning, Industrial Health Hazards, Subnormal Workers, Industrial Dermatoses, Bad Teeth and Fatigue, Industrial Clinics, Health Education in Industry, Coordination of Industry and Community Health Activities, Malingering, the Treatment of Burns, the Lessons of War Surgery, and Humanizing a Steel Plant, indicate the broad scope of the Council's work in health. In addition, the Council has a special section on Employees' Benefit Associations which deals with the insurance of health.

Physicians have come to have such an active relation to industry through the establishment of industrial medical departments and through the emergency calls which are made in cases of accidents as well as their relation to industry as consulting sanitarians and hygienists that the work of the Safety Council should be of special interest and information for them.

FACTORS CAUSING DISEASE

A CURIOUS example of reasoning without facts is found in the recent report of the majority of the Illinois Commission on Health Insurance, regarding the individual, the community, and industrial causes of disease. The majority of the Commission say:

"In our opinion nearly all disease is traceable in its ultimate causation to the individual, to the violation, through lack of understanding or wilfulness, of the well recognized laws of health or hygiene; the refusal to use the facilities for correction of physical conditions which will become disabling; excesses in personal conduct; and, a most important factor, the inherent limitations of vitality which vary in individuals from those merely able to keep alive the spark of life to those who are of the most robust and vigorous type."

And further, they add: "Any statement of a proportional responsibility of the state, industry, or the individual as factors causing disease in the aggregate is without basis in ascertained fact or creditable evidence."

The Commission made no investigation of this particular subject. There are no facts given in the report of the investigator attempting to show the individual, community, or industrial causes. The flippant statement that "nearly all disease is traceable in its ultimate to the individual" has no basis in the report, nor in the numerous investigations made by medical associations, industrial boards, and health departments.

Illinois was among the first states to consider the matter of occupational disease and the Illinois report on the subject in 1911 was the pio-

neer. The majority of the Illinois Health Insurance Commission evidently ignored all the findings of that commission and of the two-year investigation by the State Department of Health of Ohio, the numerous and exhaustive investigations of the Department of Labor Statistics at Washington, and health departments all over the country.

Furthermore, they seem to ignore the fact that nearly three out of every thousand people in the United States died last year on account of influenza and pneumonia developing out of influenza. No sensible person would presume to say that the deaths from influenza had their origin in individual causes.

That a great part of disease is due to individual causes no one doubts; but to say that practically all of it is traceable to the individual is to ignore all of the factors of heredity, early environment and neglect, community neglect, industrial hazards, and failure to educate people in health. If all men were super-intelligent and attentive to the rules of health, it might be that the community and industrial dangers could be warded off, and perhaps some of the inherited defects overcome; but this does not warrant the statement, in our present civilization, that the individual is to blame for it all. Why the majority of the Illinois Commission should have announced such a preposterous proposition is hard to understand.

SIR CHRISTOPHER ADDISON, M.D., B.S., F.R.C.S. ENGLAND'S FIRST MINISTER OF HEALTH

ON JULY 1, England's new Ministry of Health was inaugurated with Sir Christopher Addison as the first Minister. The Local Government Board went out of existence on that day and all of its functions were incorporated in the Ministry of Health. Doctor Addison, the first Minister of Health, has had a long

experience in dealing with the problems which he now faces as Minister. Doctor Addison was born June 19, 1869. He has been Hunterian Professor and Examiner in Anatomy at the Universities of Cambridge and London; formerly lecturer on anatomy at St. Bartholomew's Hospital; member of the Research

number of years editor of the *Quarterly Journal of Medicine*.

Medical men in America will be encouraged by the fact that a physician of high standing and large experience has been intrusted with the carrying out of the reorganization of health work in England along broadened lines.

THE ENDOWMENT OF MATERNITY

THE attention of many thinking people has been focused upon the problem of providing adequate maternity care for mothers by accounts of England's experience, as related by Sir Arthur Newsholme, at the regional conferences on child

welfare standards which have taken place in several large cities recently under the auspices of the Federal Children's Bureau. He termed the English plan the "first great step in endowing maternity and making maternity safe for mothers." The endowment of maternity, the better security offered to mothers in recognition of the problems of motherhood, and the better safeguarding of

the young child's health are some of the fruits which should come from the extension of public health service for mothers.

In this country the same ideal has found support in common from the public health agencies that provide maternal medical and nursing service, and the child welfare organizations. The two factors working together will hasten the day when better health standards shall exist, when there will be fewer school children handicapped by preventable defects, and the young men of the nation can meet the requirements of military service, should occasion arise, without the rejection of 30 per cent for physical deficiency. The Nation owes this recognition to its mothers.

AIR CONTROL AND THE REDUCTION OF THE DEATH RATE AFTER OPERATIONS

BY ELLSWORTH HUNTINGTON, PH.D., RESEARCH ASSOCIATE IN GEOGRAPHY, YALE UNIVERSITY, NEW HAVEN, CONN.

Part I.—Humidity

AN IMPROVEMENT of 20 per cent in the results of operations would be an achievement for which the world might willingly pay millions of dollars. Yet such an achievement seems to lie easily within our grasp: it could apparently be brought about simply by giving the air of hospitals and sick rooms the proper temperature, humidity, and variability.

Although such a statement sounds highly optimistic, it seems justified by abundant evidence, part of which has already been published in "World Power and Evolution" and in an article¹ in the first number of MODERN MEDICINE, and part of which will here be set forth. To sum up the published evidence, an analysis of 60,000,000 deaths in many countries indicates that the death rate not only depends upon climate and weather, as is well known, but is far more sensitive to slight atmospheric variations than is generally supposed. The condition of the air is the fundamental cause not only of the difference between tropical and other countries, but of large fluctuations in the death rate from year to year, and of a multitude of smaller fluctuations in health from day to day.

The Optimum for Health

The study of these millions of deaths teaches three main lessons. First, the health of most parts of the world is best when the average temperature for day and night together approaches closely to 64° F., which is the optimum for the white race. Second, and more important because less expected, at all temperatures up to the optimum, dry air does far more damage than moist; while, even at higher temperatures, extreme dryness is worse than a moderate degree, although

All kinds of ailments show a surprisingly close correlation with temperature, humidity, and variability.

Different types of disease, however, respond differently. For surgical operations the best condition, as indicated by the records of two large Boston hospitals, is high humidity, 80 per cent or more, directly after operations, and moderate humidity, about 60 per cent at a temperature of 64°, a few days later.

Such conditions can easily be produced artificially. This would probably cause an improvement of not less than 20 per cent in the results of operations.

not as bad as extreme moisture. At a mean outdoor temperature of 64° the optimum relative humidity is about 80 per cent, which means dew at night and a humidity of perhaps 60 per cent at midday in clear weather. Equally unexpected, and equally opposed to the common belief, is the third lesson, that variability in the air is just as important as in diet or occupation. A climate or room in which the atmospher-

ic conditions vary frequently but not unduly on either side of the optimum is decidedly more healthful than one that remains uniformly near the optimum.

Thus far we have been speaking of health in general, but different diseases react differently. For example, in "The Interpretation of the Death Rate by Climographs"¹ it is shown that epidemics, taken as a whole, are checked by dry heat, although this may entail increased mortality from other causes. Similarly Greenberg² has found that mortality from pneumonia diminishes when either the temperature or humidity increases, although his figures are not conclusive for high temperatures. Thus, although all types of disease may be ameliorated under the influence of the general optimum herein defined, each apparently has its own peculiar relation to certain aspects of climate. The same is probably true of different ages, of the two sexes, and of people of different occupations, physiques, and temperaments.

An Optimum for Surgical Cases

In order to remove all doubt in this important matter I have begun an investigation of different ailments and different types of people with a view to determining the best conditions in each case. The present article deals with operations of all sorts except traumatic, these being omitted because the weather conditions which cause accidents are presumably quite different from those

1. Huntington, Ellsworth: The Interpretation of the Death Rate by Climographs, *Mod. Med.*, 1919, I, 13.

2. Greenberg, David: Relation of Meteorological Conditions to the Prevalence of Pneumonia, *Jour. Am. Med. Assn.*, 1919, lxiii, 252.

which govern the speed of recovery among surgical cases in hospital. The operations have not been subdivided because of the difficulty of obtaining a sufficient body of data without undue clerical work. The problem is to determine whether the condition of the air at the time of operations and immediately thereafter has anything to do with the success of the operations. The answer is emphatically positive. Deaths after operations show not only the familiar seasonal variation due largely to temperature, but also an equally strong relationship to humidity and to variability. The present article considers humidity, while variability will be considered later.

Method of Investigation

The method of investigation employed in this article is briefly as follows: At the Boston City Hospital (1914-1918) and the Massachusetts General Hospital in the same city (1906-1915) tables were prepared showing the dates of all non-traumatic operations which were followed by death before discharge from the hospital. These were divided into groups as appears below. Operations not followed by death were all put in a single group because any attempt to estimate their success brings in the fallible factor of human judgment, whereas death is an absolute criterion, universally recognized. This group is used only as a standard from which to measure the departure of the other groups. The cases followed by death were then compared with the conditions of the outside air as recorded by the Weather Bureau. Comparison was first made with the conditions on the morning of the operation, and a distinct relation became clear. When the weather on the succeeding morning was used, however, the relationship became much clearer. This is natural, for the critical time is immediately after the operation. Accordingly, unless otherwise noted, all

statements as to the weather refer to 8 a.m. of the morning after the operation.

The Problem Stated

Among the questions to be answered immediately were: (1) does any particular kind of weather hasten death after operations? (2) how long does the weather of a single day continue its influence? Table I gives the answers. It shows how the weather at 8 a.m. on the morning after operations which resulted in death at the Boston City Hospital differed from the weather on similar mornings after operation which did not result in death.

For example, the first section of the table shows cases in which death occurred at once or on the first day after the operation. From January to March the average temperature was 0.62° higher, the relative humidity 6.1 per cent lower, and the amount of vapor per cubic foot in the air 0.095 grains less than when none of the operations resulted in death. For the year as a whole, as appears at the bottom of the table, the figures are inconclusive; although the temperature was relatively high and the humidity low, the amount of water vapor was more than the average because of the higher temperature.

In the next section where death followed the operations after 2 to 4 days, the evidence is more conclusive. The weather was cool and dry at practically all seasons, for only 4 of the 15 signs in this section are plus and the rest all minus. In the section where death followed after 5 to 10 days the tendency toward dryness and coolness is still more marked, for all the signs are minus.

When death is delayed more than 10 days, however, the effect of the weather immediately after the operations seems to disappear, for in this section no marked tendency is observable. Yet even after this long interval, days with low relative

TABLE I

AVERAGE WEATHER CONDITIONS AT 8 A. M. ON DAYS AFTER OPERATIONS FOLLOWED BY DEATH, AT BOSTON CITY HOSPITAL, JANUARY, 1914-SEPTEMBER, 1918

KEY
 A = Number of cases.
 B = Departure from average temperature at 8 A. M. on days after operations, none of which resulted fatally.
 C = Departure from average relative humidity ditto.
 D = Departure from grains of water per cubic foot ditto.

	Length of interval from operation to death.															
	6-1 days—Section I				2-4 days—Section II				5-10 days—Section III				Over 10 days—Section IV			
	A	B	C	D	A	B	C	D	A	B	C	D	A	B	C	D

Year	235	+1.24	-1.35	+.089	220	-0.82	-0.65	-.041	186	-0.60	-2.80	-.158	163	+0.53	-0.88	+.008
	(9 plus, 6 minus)				(4 plus, 11 minus)				(0 plus, 15 minus)				(7 plus, 8 minus)			

NOTE.—The averages in Table I give equal weight to each month. This is accomplished by reducing the figures in column A (for each month) to percentages of the total number of cases for the month. Thus March, with 105 deaths, has the same weight as November with 36, and the influence of the seasons is thereby eliminated.

humidity seem to produce a bad effect since most of column C is minus. Thus dry air immediately after an operation appears harmful, and the effect seems to last 10 days, more or less. It seems odd that the effect should be greater from the fifth to the tenth day than earlier, but during the first day or two the question of life or death presumably depends primarily upon the degree of shock, and only after the first struggle is over does the full influence of the air become clearly differentiated from the greater influence of the operation itself.

Air Conditions Influence Death Rate

We are now ready to find out just what effect on the death rate is produced by any given combination of temperature and humidity. It would be well to use only deaths occurring within 1 to 10 days after operations, but the records of the Massachusetts General Hospital, although ideal in most respects, enable the lapse of time from the operation to death to be determined only by the laborious process of looking up each case individually in the original record instead of merely in the index, while those of the Boston City Hospital are not easy to use prior to 1914. Hence, for the present we shall use all deaths after operations. This does not alter our results but merely makes them less striking than they would be otherwise.

Effect of Temperature

Table II shows the number of deaths per day following operations performed when the weather conditions next morning were as indicated at the

top and on the left. The lessons of the table as to temperature are summed up in the "Total" column on the right. The small number of deaths, 0.383 per day, at a temperature of 51°-60° shows that the relation of operations to temperature is essentially the same as that of health in general; for 51°-60° at 8 a.m. includes to an average of about 64° for night and day together. The low figure for very hot weather, 0.324, merely means that under such conditions surgeons do not operate if they can avoid it.

Humidity Modifies Effects of Temperature

Although temperature is presumably the most important climatic element, its effects are profoundly modified by humidity, as appears in the body of Table II. Notice how the figures for temperatures of "over 80°" and "71°-80°" are large on the left where low humidity is shown, fall to a minimum at about 60 per cent, and rise again on the right where the humidity is high. At temperature below 70° Table II discloses a favorable tendency at low humidities, but this appears not to be due to humidity, but to the fact that cold waves, which are usually stimulating when they first occur, are regularly accompanied by dry weather. We shall return to this later. In spite of a few pronounced cold waves, however, dry weather at temperatures below 70°, or more probably below 64°, is as a rule harmful. This is clearly apparent in Table III, which is a condensed summary of Table II. Notice that at temperatures below 70° the decrease from left to right, that is from low humidity to high, is almost perfectly regular.

TABLE II

DEATHS PER DAY AFTER OPERATIONS WHICH WERE FOLLOWED BY SPECIFIC CONDITIONS OF WEATHER, BOSTON CITY HOSPITAL, JANUARY, 1914-SEPTEMBER, 1918, AND MASSACHUSETTS GENERAL HOSPITAL, 1906-1915								
Temperature at 8 a. m. day after operation	Relative Humidity at 8 a. m. on day after operation							Total
	40% or less	41-50%	51-60%	61-70%	71-80%	81-90%	91-100%	
Over 80°		1.000 (0-0)	0.182 (2-2)	0.083 (1-12)	0.750 (6-8)	0.000 (0-1) (0-0)	0.324 (11-34)
71°-80°	0.937 (15-16)	0.489 (22-45)	0.244 (21-56)	0.280 (34-121)	0.347 (42-121)	0.500 (49-95)	0.775 (24-31)	0.399 (207-518)
61°-70°	0.333 (3-9)	0.329 (28-85)	0.470 (69-147)	0.417 (88-211)	0.365 (78-214)	0.410 (93-227)	0.346 (64-185)	0.393 (423-1057)
51°-60°	0.375 (6-16)	0.466 (28-60)	0.470 (47-100)	0.433 (77-178)	0.361 (70-194)	0.405 (74-183)	0.271 (55-203)	0.383 (357-934)
41°-50°	0.091 (1-11)	0.279 (12-43)	0.629 (71-113)	0.493 (80-162)	0.398 (84-211)	0.477 (75-157)	0.415 (73-176)	0.453 (396-873)
31°-40°	0.800 (12-15)	0.368 (18-49)	0.556 (83-149)	0.431 (102-237)	0.416 (79-190)	0.417 (56-131)	0.401 (55-212)	0.422 (435-956)
21°-30°	0.250 (3-12)	0.462 (30-65)	0.524 (54-103)	0.401 (55-137)	0.445 (50-112)	0.535 (38-71)	0.450 (22-49)	0.460 (252-549)
11°-20°	0.562 (9-16)	0.655 (26-38)	0.421 (32-76)	0.416 (32-77)	0.485 (17-35)	0.368 (7-19)	0.250 (4-16)	0.458 (127-277)
10° or less.....	0.545 (6-11)	0.133 (2-15)	0.447 (17-38)	0.740 (20-27)	0.650 (13-20)	0.400 (2-5)	0.000 (0-0)	0.500 (58-116)

NOTE.—To use the table, find the required temperature on the left and the relative humidity at the top. The decimal number at the point where the lines of temperature and humidity cross shows the number of deaths per day after operations performed when the weather at 8 a. m. of the next day was of the indicated kind, each hospital being reckoned as a separate unit and the two being simply added. The left hand number in parentheses indicates the number of deaths following operations performed when the given combination of temperature and humidity prevailed at 8 a. m. next day, while the right hand number shows the total number of such days.

The Norm Under Favorable Conditions

The last two columns of Table II are especially interesting. Column D shows the deaths per day under the most favorable circumstances. Except above 70°, where the figures for a humidity of 51-60 per cent (0.237) has been added in paren-

TABLE III

Temperature at 8 A. M. day after operation	SUMMARY OF DEATHS PER DAY IN RELATION TO WEATHER				
	Humidity at 8 A. M. on day after operation			Advantage of Column D over average for given tempera- ture	(40.0%)
	Under 60%	71-80%	81-100%		
Over 70 ..	0.413	0.316	0.561	0.775 (0.237)	(40.0%)
61-70	0.415	0.391	0.381	0.346	12.0%
51-60	0.450	0.395	0.334	0.271	29.2%
41-50	0.503	0.440	0.444	0.415	8.4%
31-40	0.531	0.424	0.407	0.401	9.3%
30 or less.	0.491	0.458	0.456	0.400	13.6%
Weighted average				16.8%	

theses, the most favorable conditions are clearly the moistest. The next column, E, shows the percentage by which column D, using 0.237 instead of 0.775, is less than the corresponding average for all days of a given temperature, as given in the right hand column of Table II, or else as obtained from that table by a slight calculation. In other words, the percentages in column E indicate the amount by which the death rate would have been reduced if the air at all times had been as good as under the most favorable conditions.

It is noteworthy that favorable conditions of humidity at temperatures above 70° are even more important than at lower temperatures. A little of the excellence of column D may arise from a drop in temperature due to rainy spells in the warmer months, but humidity is by far the most important element. If the outdoor air had contained its optimum complement of moisture, and if the indoor air had therefore been correspond-

ingly modified, the deaths would apparently have been diminished by 16.8 per cent. Artificial humidification would apparently produce equally desirable results.

True Importance of Humidification

In estimating the importance of humidification it must be remembered that various factors tend to make our results less striking than they really are. In the first place, we have been using all deaths after operations, including those occurring before the hour of our weather records and those so long after the operations that the effect of the initial conditions may have wholly disappeared. In order to see how far we have thus minimized our results, let us examine the deaths occurring from 1 to 10 days after operations at the Boston City Hospital. These are summarized in Table IV, which combines certain features of Tables II and III. The percentages in column F rise higher than in the corresponding part of Table III, column E, and their average, 23.2 per cent, rather than the former figure, 16.8 per cent, seems to be a fair measure of the influence of humidity immediately after operations.

A second reason why our results appear less striking than they really are is that, even when the air outdoors is saturated, the humidity within doors may still be much too low. If saturated air from outside is taken into the house and heated to 64°, its relative humidity becomes approximately as in Table V.

Only the last of the percentages in Table II is as high as is desirable after operations; hence even in the best winter weather artificial humidification is needed on a considerable scale. Conversely, in warm weather the air should be dried and cooled before being admitted to operating rooms and wards. There is as much reason to cool the summer air as to warm that of winter.

TABLE IV

Temperature	SUMMARY OF DEATHS PER DAY AT BOSTON CITY HOSPITAL COMPARED WITH WEATHER AT 8 A. M. ON DAY AFTER OPERATIONS, AND CONSIDERING ONLY THE DEATHS OCCURRING ONE TO TEN DAYS AFTER THE OPERATION					
	Relative Humidity					
	60% or less	61-80%	81-100%	91-100%	Total	Advantage of D over E
	A	B	C	D	E	F
Over 70°	0.230 (8-35)	0.213 (19-89)	0.383 (18-47)	0.200 (7-35)	0.263 (45-171)	31.5%
61°-70°	0.320 (24-75)	0.292 (36-128)	0.264 (37-140)	0.254 (16-63)	0.283 (97-343)	10.2%
51°-61°	0.268 (15-56)	0.309 (30-123)	0.215 (24-112)	0.117 (7-60)	0.264 (77-291)	56.6%
41°-50°	0.477 (24-50)	0.270 (33-122)	0.352 (34-99)	0.347 (17-49)	0.336 (91-271)	-3.3%
31°-40°	0.463 (24-53)	0.355 (44-124)	0.317 (39-123)	0.312 (24-77)	0.357 (107-300)	12.0%
30° or less.....	0.387 (48-124)	0.316 (47-149)	0.327 (20-61)	0.228 (5-22)	0.355 (115-324)	35.8%
			Weighted average			23.2%

With such treatment of the air we may reasonably hope that the death rate may be reduced not only to the level which now pertains to air with the best natural conditions of humidity, that is, by 20 per cent or more, but to a still lower level.

Greatest Humidity Immediately After Operations

A third factor which reduces the striking quality of our results is that thus far we have considered the humidity of only a single day. That first day, to be sure, is the most critical, for the patient is under the full shock of the operation; yet other days are also important, especially the day of death in cases where the patient lives beyond the first day. Accordingly, Table VI has been prepared to show the number of deaths per day when various weather conditions prevailed on the day of death. This table is based on 571 operations which were followed by death on the second day or later. It agrees with the others as to both high and low temperatures. At high temperatures extreme dryness, 0.372, is not as good as moderate dryness, 0.276; but extreme humidity is much worse, 0.462. At temperatures below 50° the death rate decreases quite steadily with increasing humidity.

At intermediate temperatures, however, the most favorable conditions appear to shift gradually with temperature so that at all times they correspond as nearly as possible to an indoor humidity of not far from 60 per cent after the air has been heated and has received the usual increments of moisture from furnaces, from peoples' breath, and from other sources of evaporation. This suggests that, whereas immediately after an operation the relative humidity should be as high as practicable, that is 80 per cent or more, it should gradually be diminished so that after a few days it averages about 60 per cent when the temperature is 64°. Even that, however, is about twice as great as the humidity of the ordinary house or hospital in winter.

From the foregoing facts it appears that if the right conditions prevailed at the time of operations, and if there were also a gradual change to somewhat dried but still compara-

tively moist conditions after the operation, each process would entail a theoretical decrease of nearly 20 per cent in the death rate. This, be it remembered, takes account of only two days, the one directly after the operation and the one when the death occurs. If the days between these two

TABLE V

RELATIVE HUMIDITY OF SATURATED OUTDOOR AIR AFTER BEING TAKEN INTO HOUSE AND HEATED TO 64°

Outside Temperature	Approximate relative humidity indoors at 64°
25°	24%
35°	36%
45°	52%
55°	75%

were considered, the effect would be still greater. Hence the hope that proper attention to humidity may cause a saving of 20 per cent in the total death rate after operations seems conservative.

How to Attain Humification

The actual process of humification is relatively simple, although most of the humifiers now on the market are inadequate. At least two processes, however, are comparatively effective. One is where warm air is blown through a shower of spray; the other, which is much cheaper for buildings where the heating plant is already installed, consists in suspending cloths like wicks with their lower ends in dishes of water and with their upper parts spread out back of radiators or in other suitable positions. This method is explained in detail in an appendix in "World Power and Evolution." A practicable modification, where hot air is used, consists of a series of non-inflammable wicks placed in the hot air chamber with their lower ends in pans of water and their

TABLE VI

DEATHS PER DAY AT AN INTERVAL OF TWO DAYS OR MORE AFTER OPERATIONS AT THE BOSTON CITY HOSPITAL, COMPARED WITH WEATHER CONDITIONS ON THE MORNING OF DEATH

Temperature at 8 A. M.	Relative Humidity at 8 A. M.							Advantage of underlined conditions over average H
	40% or less A	41-50% B	51-60% C	61-70% D	71-80% E	81-90% F	91-100% G

Weighted average								9.3%

NOTE.—Deaths occurring on day of operation and on the next day are omitted because already considered. In this table, unlike the others, the figures for deaths per day, but not those in parenthesis for number of deaths and number of days have been smoothed by averaging groups of three in each horizontal line. This is because the number of cases is less than elsewhere, and smoothing is needed to obliterate accidental variations. Such variations are probably the reason why the line for 61-70° continues to diminish to the left of column D.

upper ends suspended from sprinkling pipes with rows of holes opening on both sides of the wicks. An automatic valve in the pans opens when the water becomes too shallow, and thus allows the sprinklers to play on the wicks until enough water trickles down to fill the pans again.

Whatever method of humidification is used, it must be remembered that if the air is to be comfortable and healthful, it must be comparatively cool. Air with a temperature of 65° and a relative humidity of 70 per cent, as any one can see on many a day in the spring and fall, feels perfectly comfortable to people who want a tempera-

ture of at least 70° when the air is dry in winter. It must also be remembered that variability as well as humidity is needed.

The evidence that health could be much improved by proper humidity seems overwhelming. So, too, does the evidence that the human organism is amazingly sensitive to slight changes in the atmosphere. Nevertheless, our knowledge of the whole subject is still very imperfect. Hence everyone who tries experiments along the lines here indicated is urged to publish the results, or at least to communicate with the author or with the editors of this magazine.

MEDICAL SUPERVISION OF STUDENTS AT WISCONSIN

BY C. R. BARDEEN, M.D., DEAN OF THE MEDICAL SCHOOL, MADISON, WISCONSIN

MEDICAL supervision of health in an institution or a community may be subdivided into three overlapping parts: (1) prevention of the spread of infectious diseases, (2) promotion of good hygienic conditions, and (3) personal care.

The prevention of the spread of infectious diseases in regions such as that in which the University of Wisconsin is situated is largely a matter of the prevention of personal contact infections. Insects play a minor rôle. The water and food supplies play a somewhat greater rôle but one much less than that of personal contact. The chief problem in prevention is that of prompt discovery and prompt isolation of infected individuals. In a university community this is the more important because of the opportunities offered for contact infections by the crowded conditions of class rooms, boarding houses, and, frequently, of rooming houses.

The Control of Infectious Diseases

For the sake of early discovery of cases of infectious disease, the students and those interested in their welfare are encouraged to report all cases of illness, however trivial they may seem, promptly at the university clinic. The regular hours for students to call at the university clinic are from 1:30 to 4:30 each afternoon. Ap-

HEALTH A COMMUNITY ISSUE

Medical supervision of the health of a student body involves more than disease treatment, or even disease prevention.

It embraces the study and care of the health of the community as a whole, and includes in its reach the hygiene of the environment.

It must meet the health needs of each individual, both immediate and as they relate to the future.

The centralized and perfectly functioning health work at Wisconsin could well be expanded to take care of a municipality, or a state.

day or night and are visited by members of the staff. Students are encouraged to feel that it is their duty to report promptly when ill, not only for their individual welfare but also for that of their fellow students. In general the response has been gratifying. Not infrequently cases of mumps have been isolated before the parotid gland has begun to swell, the diagnosis being made in the appearance of the salivary duct.

The prompt discovery of an infectious disease is of little value, so far as the community at large is concerned, unless it is followed by prompt isolation. Proper isolation is seldom practical in the houses in which most of the students room. Furthermore, if a student is isolated for the sake of the community it is only fair that he should be furnished medical attention during this period, and medical attendance, when cases are widely scattered, is time-consuming. We have therefore maintained an infirmary at the university to

pointments may be made in advance. A staff of several physicians is in attendance. At certain seasons from 150 to 200 students out of a student population of 5,000 may visit the clinic in a single afternoon. The average number is about one hundred. In case of emergency students may call at the clinic at other hours than those specified, either morning or evening. Students confined to bed by illness can telephone the clinic

which students can be sent. Hitherto we have not had one adequate for our needs. During the influenza epidemic the University Club and several private houses were utilized as infirmaries.

We have recently completed a new student infirmary with a sixty-bed capacity. This cost, equipped, about \$110,000. Of this amount \$50,000 was contributed by private individuals, the

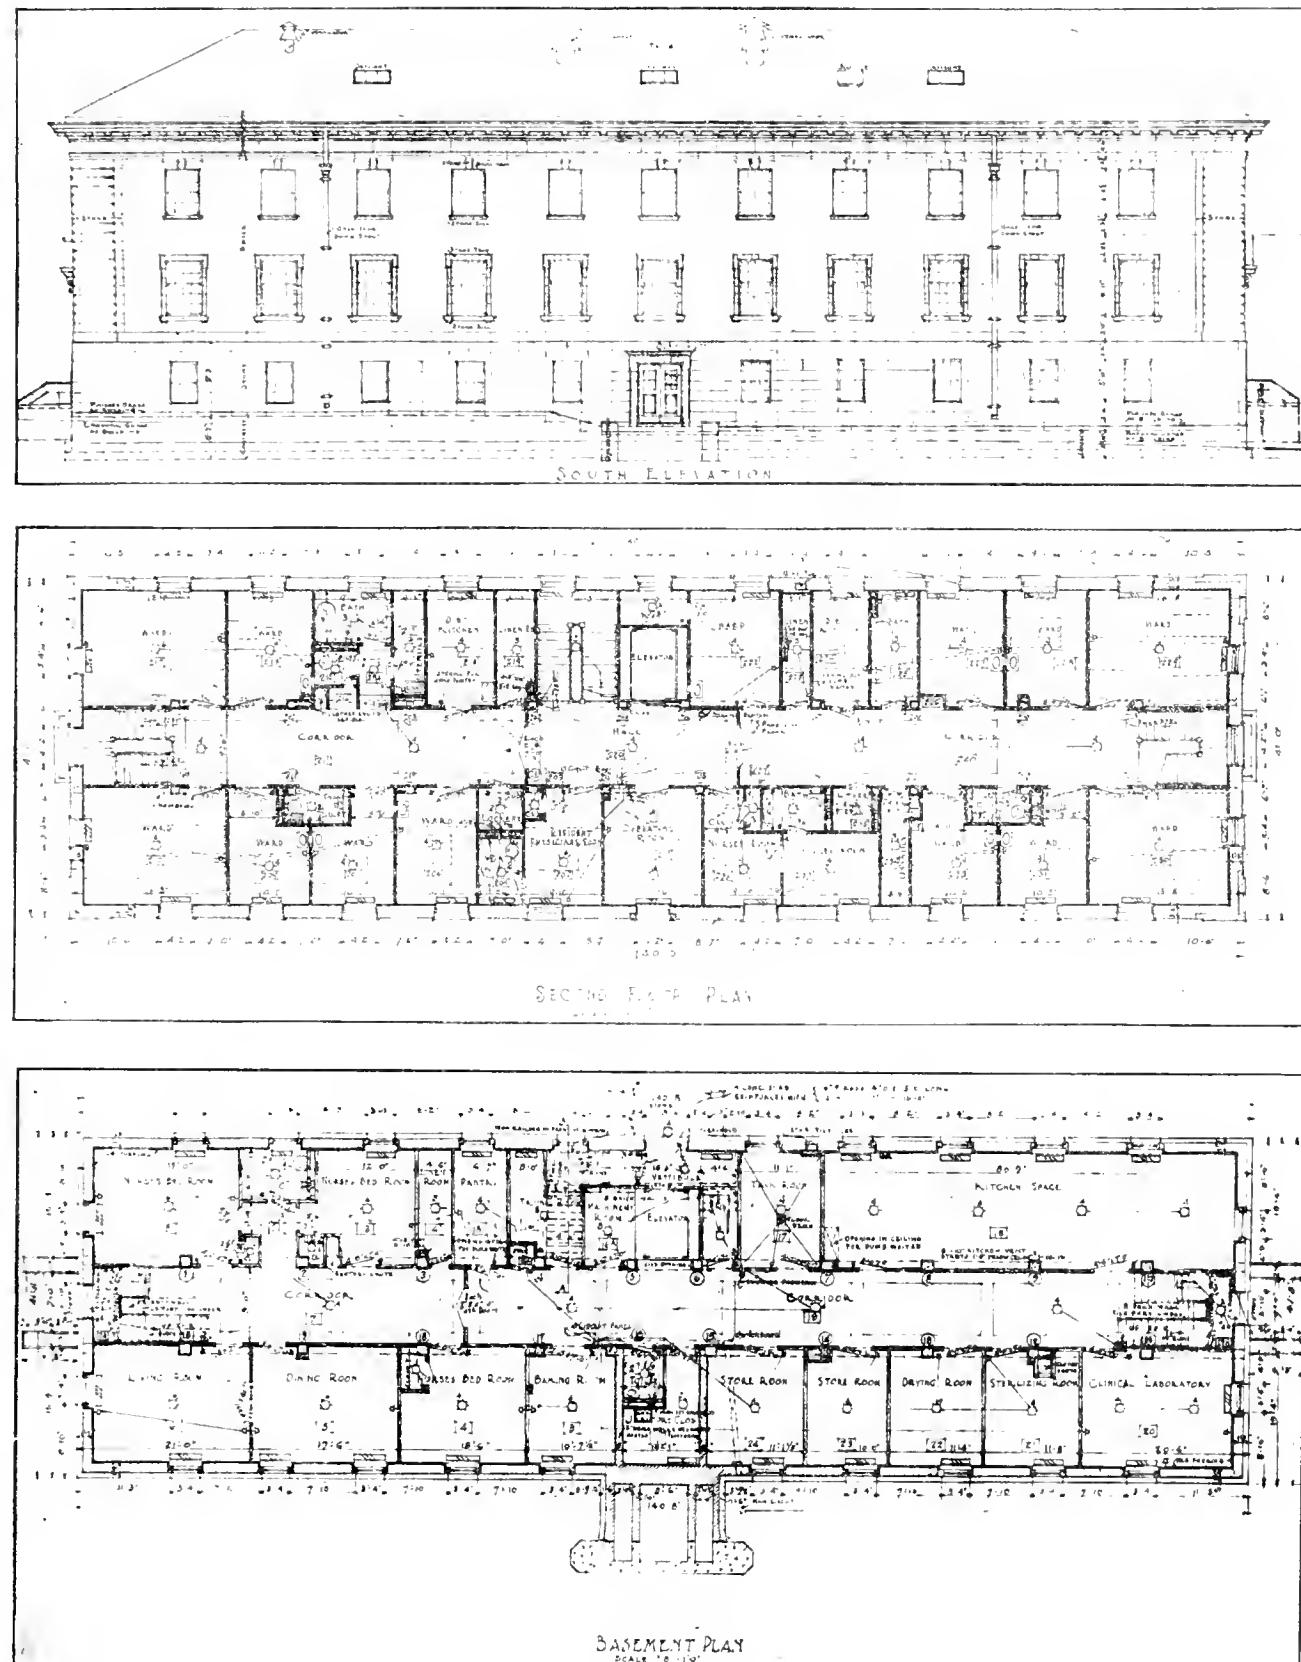

Fig. 1. Elevation, second floor and basement plans of University Infirmary.

rest by the state. Figure I shows an elevation, basement and second floor plans of this building. The building is arranged for the isolation of various groups of cases of each sex. Provision is made for the use of other buildings in case of epidemics of unusual proportions. Each student is charged an infirmary fee of \$3 per semester. This entitles him to care at the infirmary during periods of acute illness without extra charge. Hitherto a *per diem* charge of from \$1 to \$1.50 per day has been made, but it has seemed best to make community charge for the care of patients who in the main are cared for at the infirmary as much for the welfare of the university as a whole as for their own.

The Promotion of Good Hygienic Conditions

Under this heading come many factors. It is obviously the duty of the university authorities to provide good conditions of lighting, heat, ventilation, and plumbing in the class rooms and laboratories, and to schedule work in such a way as to promote physical and mental efficiency. The sanitary conditions of the dormitories and commons likewise should be of the highest standard. For the promotion of these ends the medical supervisor and his staff as well as other members of the medical faculty act in an advisory capacity. The supervision of sanitation in rooming and boarding houses not under direct university control is more difficult. Much, however, can be done indirectly through such control as may be exercised in guiding students in the choice of rooms and board, and directly by appeal to the managers of such places for cooperation. Our experience has been that more can be accomplished in medical supervision by informally inviting cooperation than by formal inspection and a show of force which in the nature of things must be in part a bluff.

Facilities for Physical Exercise

In another field the university endeavors to promote hygiene by offering facilities for physical exercise. These facilities are under the supervision of the department of physical training and include gymnasiums for men and women, playgrounds, and equipment for lake sports. At Wisconsin, however, we are coming to look upon the department of physical education as primarily an educational department rather than a hygienic institute. While the facilities of the department offer opportunities for healthful exercise and provision is made for corrective exercises for those who may need them, the primary function of the department is training in skill in muscular activity and in training teachers for this work. The

well developed individual should have not merely a healthy mind but a trained intellect, not merely a healthy body, but one that can be used gracefully and efficiently.

In so far as the department of physical education has to do directly with the personal hygiene of students it acts under the advice of the medical supervisor. The medical department has charge of the medical care of the athletic teams.

Personal Care

Under the term "personal care" as a part of the work of medical supervision we mean work done for individuals for their personal benefit. The average student, when he enters the university, has some physical defects, slight or marked, the result of heredity or environment. He comes from a home in which he has been surrounded by loving care, and where much more thought has been given by others than by himself to consideration of his health. At the university he is thrown more upon his own resources and has to develop new habits of personal hygiene. An important part of the work of the medical supervisor is to learn to know the students as individuals and to give such advice concerning personal and public hygiene as will help the student to make the most of himself as a student and to prepare himself to make the most of himself subsequently as a citizen.

Each student when he enters the university is required to undergo a medical examination, the results of which are recorded in condensed form on a 5x8 inch card, a reproduction of which is shown in Figure II. These examinations are made during the first ten days of the school year. Appointments for medical examination are made at the time of matriculation. On the basis of this medical examination the students are divided into four groups, A, B, C, and D, from the standpoint of scholastic work, and into four groups, a, b, c, and d, from the standpoint of physical activity. Students not in class "A" or "B" as a rule require special medical supervision in the selection of studies or hours of work. Students in class "a" are not restricted as to physical activities; those in classes "c" and "d" require special supervision over their physical activities.

Cards signifying the classification of the students are sent to the university officers in charge of the scholastic or physical training of the student. Students whose presence at the university would be clearly detrimental to their own welfare or that of their fellow students, cases of active tuberculosis, for instance, are excluded from the university. Students whose physical condition seems to demand it are required to report from

Fig. 3. A laboratory card is kept for each student. It bears a number corresponding to that on his other clinical records.

After the medical examination of a matriculant is made he is free to call upon the medical adviser for medical advice at any time and is encouraged to do so. The department of clinical medicine gives medical treatment to students who desire it when in the opinion of the medical staff this treatment can be given with advantage to the student or to the university; but students requiring the services of surgeons or other specialists are referred to private physicians either in Madison, at the student's home, or elsewhere. No charge is made for medical advice, supervision or treatment furnished by the university, but the expenses of this work are in part met by incidental fees paid each semester. The university is under no contract to furnish medical care. Students are charged at cost for x-ray plates and other materials furnished at the office of the medical adviser. The number of calls at the office of the medical adviser run from 30,000 to 40,000 per year but the majority of these are for trivial complaints which enable the medical staff to put in the one stitch that saves nine. About 80 per cent of the

increased rapidly during the first few years after it was started, the percentage of students with acute nasopharyngeal infection, in whom complications developed, infection of the eyes, ears, and the like, decreased from about 50 per cent to less than 10 per cent and the average time lost from work from $8\frac{1}{2}$ to $2\frac{1}{2}$ days. The habit of prompt reporting of illness has decreased rather than increased morbid worry about one's condition. The use of patent medicines, frequent before the work was organized, has practically disappeared.

Each student is given a serial number at the time of the medical examination made when the student matriculates. An envelope is stamped with this number and in this envelope are placed the condensed record of this medical examination and records of all subsequent medical consultations, laboratory examinations, correspondence with the family physician or with specialists to whom the student may have been referred, correspondence with his relatives, and similar data. These envelopes are kept on file and each time a student visits the office the envelope is looked

up and sent to the physician whom the student consults. The physician adds a note concerning the consultation and the envelopes are filed away each evening. Cross reference index cards are kept on file arranged both alphabetically and by diseases (Figs. III and IV).

Statistical summaries are made each year of the matriculation medical examinations and each month and each year of the morbidity record. While these statistical studies have been made the basis of published studies of certain special conditions, they have not been published in complete form because we have aimed at the publication of conclusions based on a large amount of data rather than of mere dry statistics.

The work thus briefly outlined started in a modest way. The immediate incentive to the establishment of medical supervision of student health at Wisconsin was an epidemic of typhoid fever which occurred in the fall of 1909, and during which some forty students were taken ill and several died. The spread of the disease was ascribed to lack of centralized supervision. The students afflicted called in different physicians and it was not realized that an epidemic had started until many were ill. The disease

was spread from a student who waited on table at a boarding house and was a carrier. The faculty of the medical school was asked to organize a system of medical supervision.

Wisconsin offers merely the first two years of the medical course. A new department of clinical medicine was established in the medical school for the purpose of having direct charge of the medical supervision of student health, for research, and for teaching such clinical work as properly comes within the first two years of the medical course. The professor of clinical medicine was made medical adviser of the students.

The department was established with the appointment of a full-time physician as professor of clinical medicine and medical adviser who began work in February, 1910, with a woman laboratory assistant. It was planned at first that he should work in cooperation with the private practitioners in Madison in keeping record of student illness and seeing that prompt attention was given. This plan did not prove practicable owing to the failure to obtain the required cooperation. It therefore became necessary to enlarge the staff and to give treatment not only for minor conditions but also for most medical cases. In no other

way could a satisfactory record be obtained of the morbidity prevailing at the university at any given time.

From the teaching standpoint, also, the staff had to be enlarged because of the increased amount of clinical work which many of the better

for office space. This house (Figs. V and VI), now known as the "clinical building," is provided with waiting rooms for men and women, offices, laboratories, and x-ray rooms for the diagnosis and treatment of office cases. Each physician has two connecting offices so that while a patient is

Fig. 6. The University Clinical Building.

schools began to put in the second year of the medical course. Furthermore, the public demand for opportunity for medical consultation at the university led to the establishment of regular hours for this work, those able to pay being charged the usual consultation fees and the fees being turned into the state treasury. The staff has accordingly grown rapidly. For the coming year provision has been made for two professors, three assistant professors, two instructors, five assistant physicians, three laboratory assistants, two interns, a hospital superintendent, four or five supervising nurses, pupil nurses, several stenographers and clerks, a dietitian, cooks, maids, janitors, and other help. The budget has grown from less than \$10,000 to more than \$80,000. A considerable part of the budget is met by revolving funds such as clinics, infirmary, and hospital fees. It covers the cost of teaching and research as well as that of medical supervision and infirmary care.

Physical Equipment of Department

The offices of the department were at first in a small house which soon proved to be quite inadequate. In 1912 possession was taken of a larger house to which a considerable addition was made

getting ready in one room the physician can examine another in the other room. In this way a large number of patients may be examined in a short time. Patients needing further study are given special appointments.

For hospital care use has been made of the facilities of the two local general hospitals, of the city isolation hospital, and of houses owned or rented by the university. The completion of the new infirmary will enable us to take care of medical cases except in time of unusual epidemics when use will also be made of certain houses owned by the university. Cases requiring major surgery will as a rule be sent to one of the local general hospitals although provision is made for emergency surgery at the university infirmary.

Personal and Public Hygiene

The desire to form habits which will promote the greatest physical and mental efficiency is leading an increasing number of students to seek advice concerning personal and public hygiene. The majority of students are idealists who desire to develop the best that is in them. A quiet talk with a physician familiar with the problems of health from the standpoint of the student is of far greater value than attendance on a course of

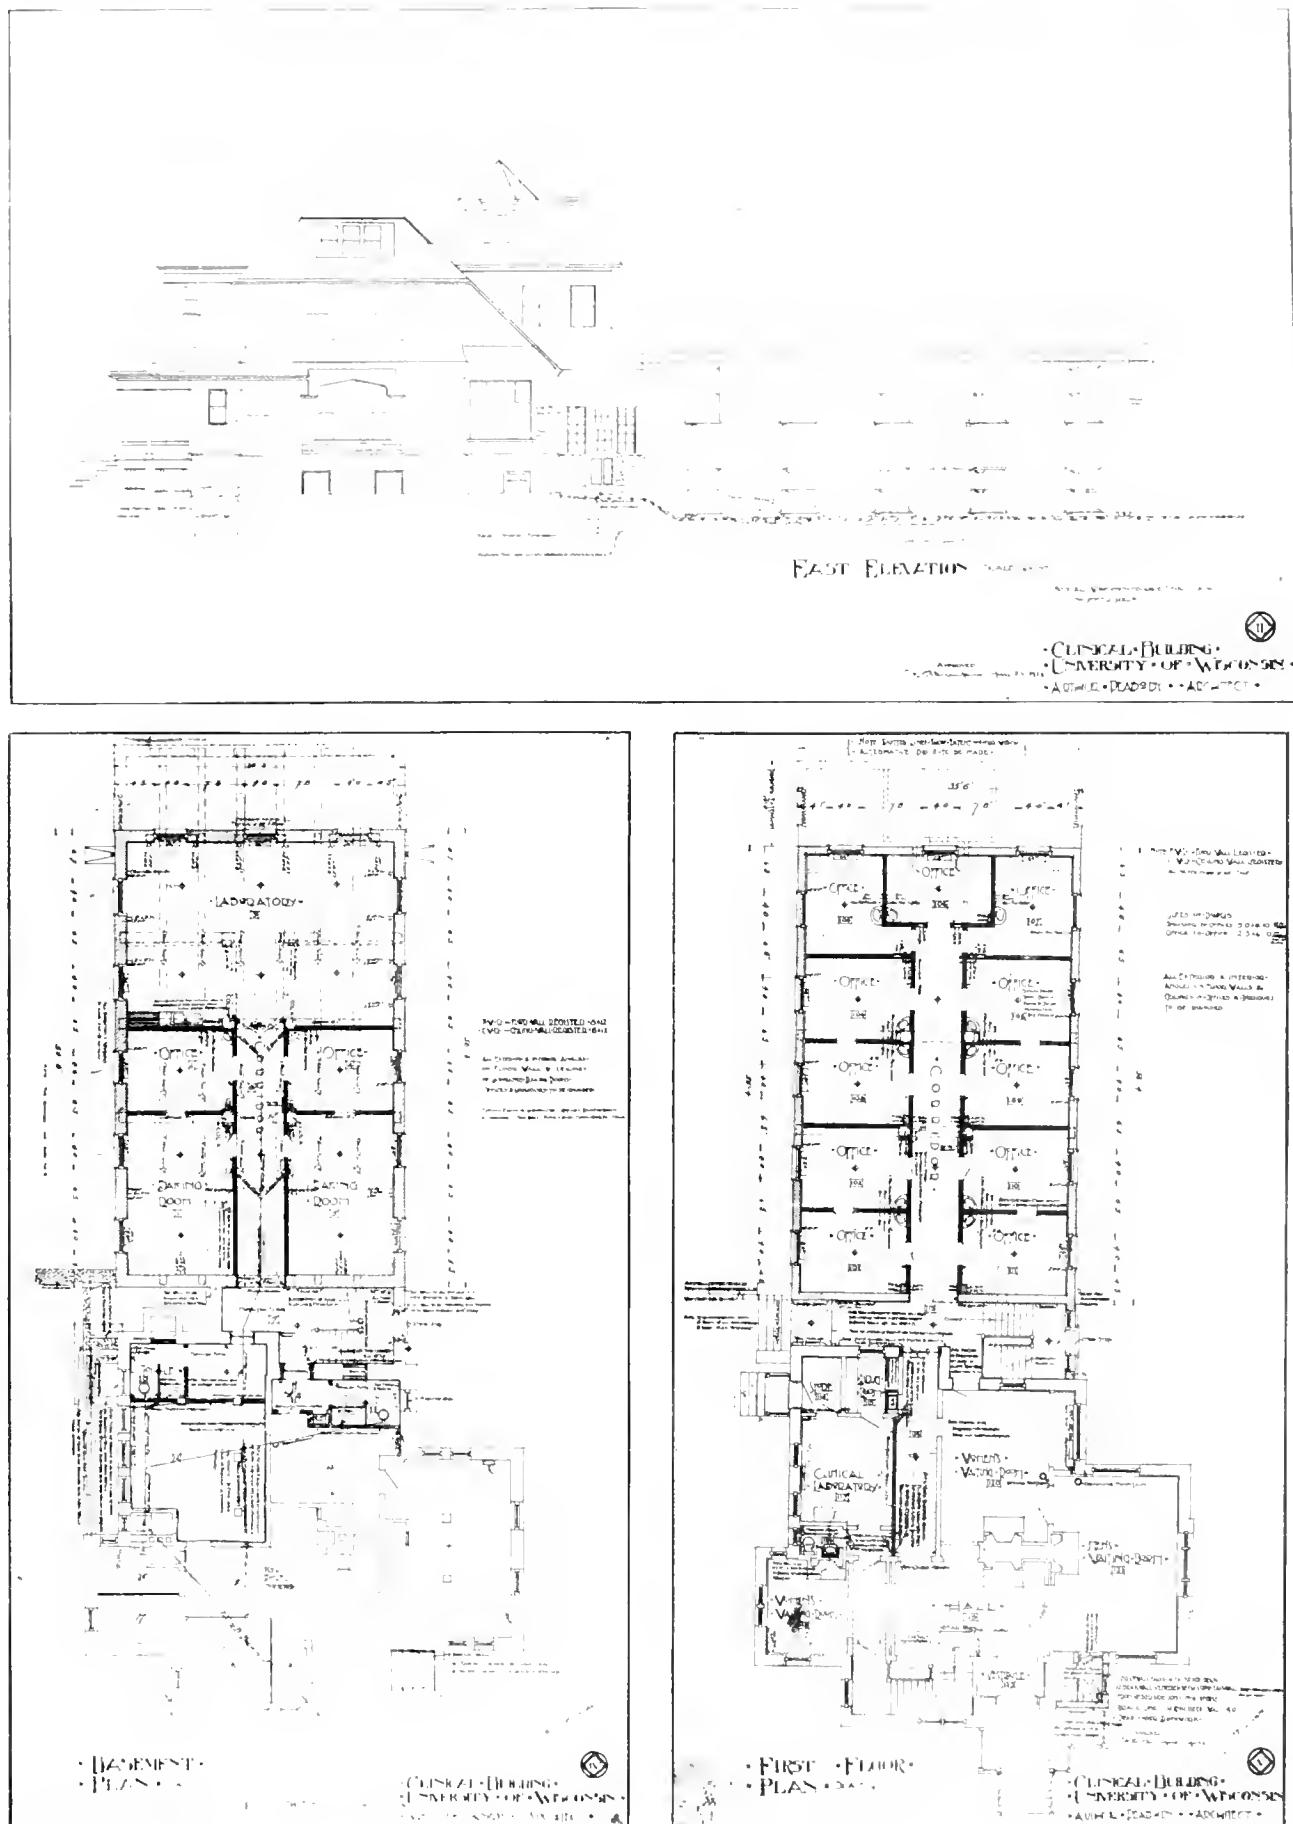

Fig. 5. Elevation and floor plans, Clinical Building.

lectures on hygiene. For several years the faculty of the medical school has conducted an elective course of lectures on personal and public hygiene in which various topics have been treated

by specialists, members of the medical faculty, and others. These lectures have proved popular, judging from the large number of students who have attended them; but we have felt that they

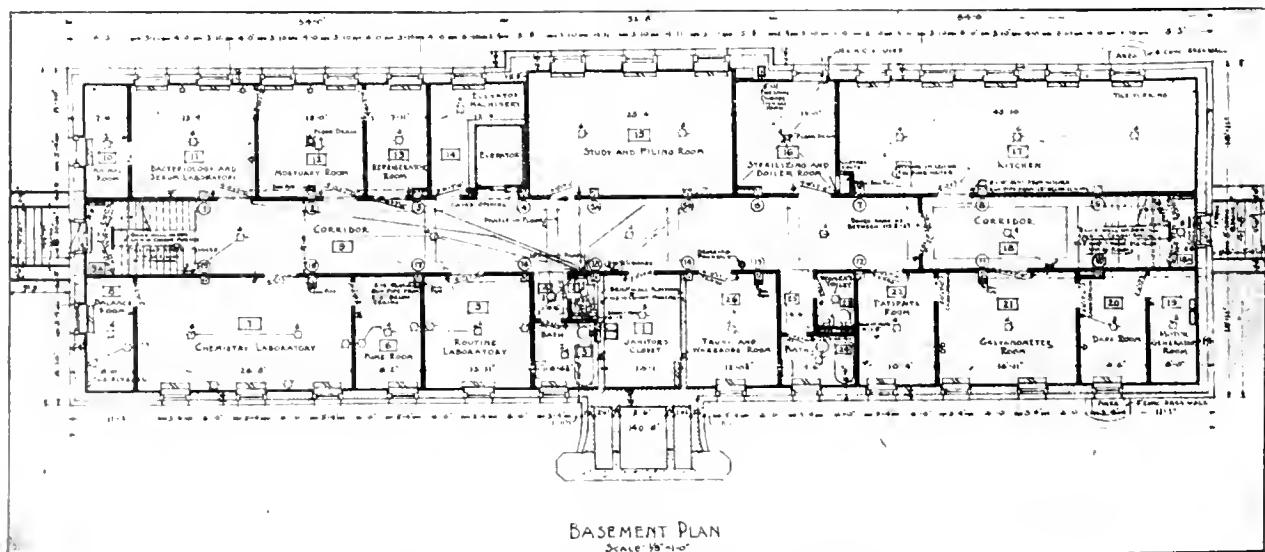

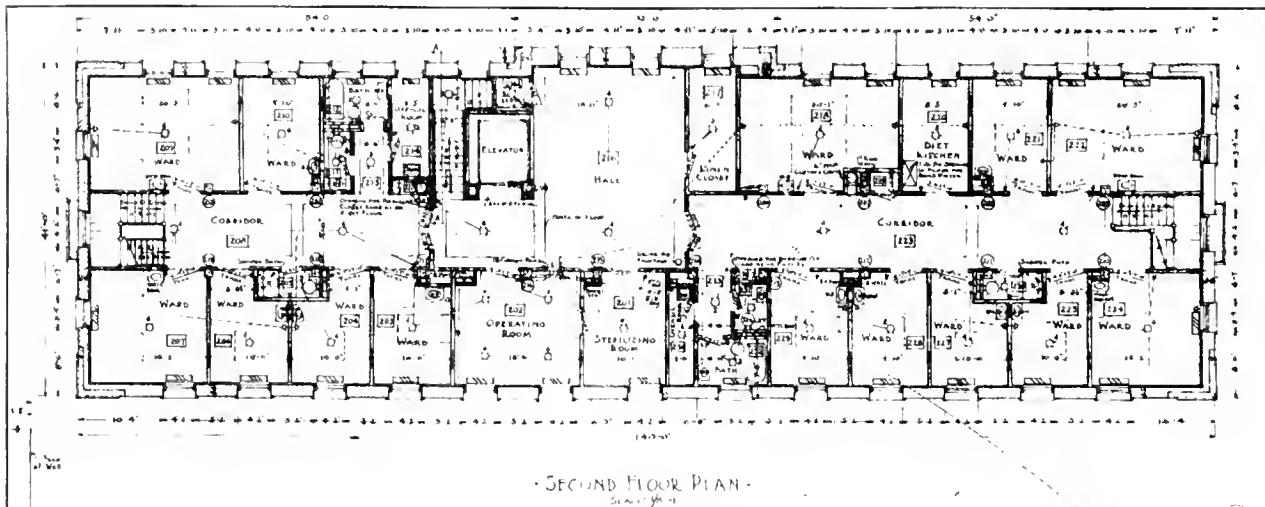

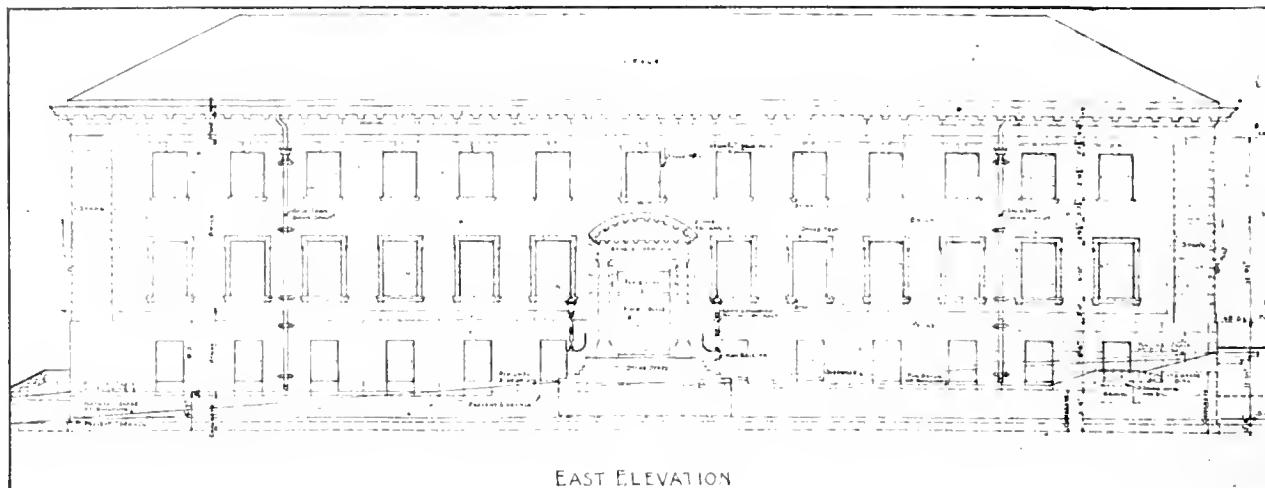

Fig. 7. Elevation, basement and second floor plans Bradley Memorial Hospital.

have been far less effective in achieving results than the personal talks referred to. This is especially true of questions of sex hygiene.

We have looked upon the work of medical supervision of the students as offering unusual facilities for the study of disease conditions at an earlier stage than they ordinarily come under the observation of the physician. It also offers a good opportunity to study morbidity in a large group of young individuals in relation to their present environment and to conditions preceding their entrance at the university. The outside consultation practice makes it possible to study morbidity in individuals below or beyond college age and to compare this morbidity with that observed in college students. Thus a broad background is offered for specializing in the conditions of health and disease presented in the student community. This scientific study of disease will be greatly facilitated by the Mary Cornelia Bradley Memorial Hospital which has recently been completed from private gifts at a cost of over \$100,000. This is a forty-bed hospital especially designed for intensive study of selected groups of cases. Figure VII shows an elevation, basement and second floor plans of this hospital. On the first floor are x-ray and physiological laboratories, and a children's ward.

In conclusion, we may summarize the aims of medical supervision at Wisconsin as embracing the study and care of the health of the community as a whole, including the hygiene of the environment, and the study and care of the health of students as individuals both immediate and in relation to their future.

PHYSICIANS FORM NEW ORGANIZATION TO COMBAT HEALTH INSURANCE

The Physicians Protective Association has been formed in Buffalo independently of the district branch of the State Association to combat health insurance in the state legislature. Dr. Earl Lathrop is the secretary-treasurer and chief organizer of the movement. A call has been issued to over one thousand physicians in western New York to join the Association, with the plea that health insurance constitutes a menace to medical men. As a result of the plan to have a symposium on health insurance at the district meeting of the state Association, several physicians who were members of the Protective Association withdrew from the program. The New York State Association has a special committee making a study of the subject of health insurance.

TRAINING FOR HOSPITAL SOCIAL SERVICE

The Boston School of Social Work offers during the coming season special courses for the training of workers in social service in hospitals and dispensaries.

Superintendents and doctors in modern hospitals and dispensaries recommend a social service department as essential to a well-equipped medical institution. The demand for women with special qualifications and training

Liberal Party Leader

Photo from Underwood & Underwood, N. Y.
HON. W. L. MACKENZIE KING

THE Honorable W. L. Mackenzie King has been chosen in the Convention of the Liberal Party in Canada as the party leader, taking the place of the late Honorable Wilfred Laurier. Mr. King is well known to the students and workers in industrial hygiene in the United States. He has made a public reputation largely in the field of labor improvement, and has been the author of numerous reports and treatises on industrial hygiene. The people of the United States are interested in Mr. King's work also because much of his time has been spent for the past few years in this country investigating the subject of industrial relations for the Rockefeller Foundation. The results of these investigations have recently been published in a book of outstanding merit—"Industry and Humanity." Mr. King is one of the younger leaders of Canada, being only 45 years old. He was a trusted friend and dependent of the former leader, Sir Wilfred Laurier.

to deal with the problems of family life and community relations, as they occur among people who are physically or mentally ill, is increasing greatly.

A one-year course is open in general social work, with special attention to medical-social service. There is an advanced class entirely devoted to medical social service for those who have had the necessary preliminary experience or training.

The Boston School of Social Work is affiliated with Simmons College, and those completing courses at the school receive certificates, or under certain conditions a degree may be obtained. For circulars giving the details of the courses, the tuition fees, etc., write to Director, School of Social Work, 18 Somerset street, Boston.

THE UNIVERSITY OF IOWA AS A STATE MEDICAL CENTER

BY HAROLD CHAMBERLIN, UNIVERSITY OF IOWA, IOWA CITY, IOWA*

TO SERVE the state as a medical and health center the University of Iowa extends medical and surgical treatment without cost to all Iowa's indigent people. The university belongs to the citizens of Iowa; rightly, they should benefit from it.

Most of the university's work which reaches beyond the student body is done by the college of medicine. Crippled children are made to walk and play; little folk who are sick are nursed back to health and happiness; blinded youngsters are made to see, and the deaf to hear. Adults, likewise, may receive whatever treatment they need. The mentally deficient will soon be examined and cared for in a special department which will be housed in a new hospital building. The university hospital does the only government reconstructive work for wounded soldiers in the state.

A Service for the Whole People

But the work of the university for the people of Iowa does not come to an end in the hospital. Problems of the normal child are studied in the Iowa Child Welfare Research Station. In the infirmary of the college of dentistry teeth may be treated with charge made only for the materials used. The State Bacteriological Station, which is located at the university, tests milk and water that the people may drink nothing impure; Wasserman tests in the interests of public health are done in the laboratory; examinations are made for rabies, and the Pasteur treatment given; the state epidemiologist takes charge of epidemics which may occur, and works to prevent outbreaks of disease.

Greatest benefits result from the Perkins law and the Haskell-Klaus law, both of which provide that indigent patients may be accepted at the hospital and cared for at the expense of the state. Four years ago the state of Iowa made its first venture in this field when the legislature passed

A PRACTICAL HEALTH PLAN

A wide extension of restorative medicine is achieved in Iowa, corrective facilities having been made available to indigent cripples throughout the state.

The University hospital has become a health center for the entire state, and a teaching center for the profession.

The work of restoration has not obscured the importance of research in health conservation.

Diagnosis, psychopathy, nutrition, medical extension service, and the coordination of all agencies have as their objective the best service to the greatest number.

under its provisions. On July 1 of this year the Haskell-Klaus law, extending free treatment to indigent adults, came into effect.

Patients are received at the general hospital of the University of Iowa, which is the largest hospital in the state. It has a capacity of 585 beds.

During the year ending June 30, 1919, 5,343 cases were treated. The university hospital is the second largest teaching hospital in the United States, being exceeded only by Johns Hopkins. It is operated in connection with and as a part of the college of medicine, and in the hospital the students in medicine and in nursing receive their training.

The college of medicine has gathered together a most capable faculty. Dean L. W. Dean is the chief of the head specialty department of the hospital. C. J. Rowan is the hospital surgeon. Some of the more important departments are internal medicine, in charge of C. P. Howard; gynecology and obstetrics, directed by W. R. Whiteis; skin diseases, J. B. Kessler; genito-urinary diseases, N. G. Aleck; nervous diseases, Clarence Van Epps; children's diseases, A. H. Byfield; orthopedic surgery, Arthur Steindler.

The hospital accepts three classes of patients. Private cases pay all expenses incident to treatment. Clinical patients are received at a nominal charge covering the actual expense of hospital care, but making no allowance for professional

the Perkins bill, which provides treatment free of expense to the patient for any child who is "under sixteen years of age and is afflicted with some deformity or suffering from some malady that can probably be remedied," and whose parents are unable to provide means for the surgical and medical treatment and hospital care of the child. Since the law became effective more than 3,000 cases have passed through the hospital

under its provisions. On July 1 of this year the Haskell-Klaus law, extending free treatment to indigent adults, came into effect.

Patients are received at the general hospital of the University of Iowa, which is the largest hospital in the state. It has a capacity of 585 beds.

fees. Perkins and Haskell-Klaus patients have the entire expense for their care paid by the state.

The most interesting work done at the university is for children. In the four years since the Perkins law has been operative, the children's de-

partment has grown so rapidly that a special hospital became necessary, and now the Children's Hospital, admirably situated on the west side campus, gives adequate provision for the treatment and care of the little folk. The building is

Crippled children at school.

A machine for every muscle—the orthopedic gymnasium, a unique feature which is run in conjunction with the orthopedic clinic.

Studying speech defects with the aid of the dictaphone in the Child Welfare Research Station.

A room of the baby ward, where pure democracy reigns. The babies do not draw race distinctions. The white and colored babies enjoy equal rights.

The milk laboratory in the Department of Pediatrics. The milk used in the children's hospital is tested every day. The laboratory diet kitchen, which is provided with a separator, a specially constructed pasteurizer, pressure cooker, sterilizer, fat tester, and other appliances. Every possible modification of milk may be obtained.

Above—a sun bath on the porch of the girls' ward. Below, at left—interior of the girls' ward in the Orthopedic Department. Below, at right—porch of the boys' ward at the recreation hour. Every face wears a smile, for the spirit of cheerfulness is all-pervading at the Children's Hospital.

Examining casts in the plaster cast room. The most interesting feature of the medical extension project at the university is the work done for children.

constructed entirely on one floor, planned with a series of wings reaching out from the administration rooms in the center. The hospital is an independent unit in itself and is equipped to care for any case. Rooms are large, airy, and well lighted, and the high ground and shady lawn on which the building is placed provide a cool spot in which the patients may live. The wards and smaller rooms open on wide, concrete porches, and it is possible for the beds to be wheeled out-

dred children are being treated in wards and private rooms which were designed for a capacity of seventy-five.

About 50 per cent of the deformed children are infantile paralysis cases, or cases resulting from infantile paralysis. The remaining 50 per cent includes other types of paralysis, cases of congenital deformity, ailments of the joints, and miscellaneous types.

A prominent feature is the work with hands

The General Hospital of the University of Iowa.

of-doors through French windows. At the Children's Hospital as well as at the general hospital all departments are favored with unusually large laboratories for research.

In its work for crippled children the university has achieved notable success and awakened much popular and professional interest. The orthopedic clinic in the university hospital, under the direction of Doctor Steindler, is one of the most widely known in the United States. By bringing strength and health to little cripples, straightening legs and arms and backs, and helping these boys and girls to be able to live as normal children the university performs a great service. These youngsters will grow into men and women able to care for themselves; they will contribute to economic life rather than burden the state, their home communities, and their parents and friends with their afflictions.

In the Children's Hospital only orthopedic cases and cases in internal medicine are accommodated; eye, ear, nose, and throat, and surgical patients are treated in the larger general hospital. Yet the Children's Hospital is incapable of caring for the demands made upon it. In the orthopedic department at the present time more than a hun-

and the upper extremities, of which there is a more than ordinary percentage of cases. In this department there were about seventy-five cases last year. Almost always the first treatment is operative. After the patient is able to use the hand or arm there begins the gymnastic treatment, or medical mechanics. This is followed by muscle education and, later, by vocational training. The whole field of preparing the child to make use of his new abilities is covered in detail, and the work is coordinated in order that children in school may have gymnasium treatment and muscle education while their vocational training is going forward along lines which they are best qualified or adapted to follow.

Heliotherapy

Cases of tuberculosis of the spine are treated by the Hibbs operation, which is very difficult and dangerous but of great benefit to the patient. All cases of joint tuberculosis are exposed to the sun according to the Rollier schedule worked out in Switzerland. This treatment has been found very beneficial in America.

In the case of a stiff joint it often happens that the hand or foot is so displayed as to be useless,

in which case the operation is to straighten the joints and put them in position where the member may be of service. Some of these cases recover complete use of the joint; in adults it is often possible to make new joints of soft tissue. However, it must be remembered that the work of the hospital is to help as well as cure and, even if a limb does not function perfectly after treatment, improvement is often so great as to be of the greatest value. In the work with joints, cases calling for proper alignment of club feet are among the most usual.

After a joint has been repaired through an operation, oftentimes its use is a question only of muscles. Too often no muscles are available, and the problem is to arrange the limb so it may be of some service without. In a few cases it has been possible to transfer muscles from one part of the body to another in overcoming this difficulty just as bone grafting, often resorted to, is a great aid in the creation of new joints. Many joint troubles are of syphilitic origin.

Spinal cases are frequently among the most interesting from a medical standpoint. Besides the Hibbs operation by Doctor Steindler, curvature is treated by fusing and the bones are straightened and strengthened.

Mechanotherapy

In the gymnasium of the orthopedic department a machine is at hand for the development and education of every muscle in the human body. Last year gymnasium exercise was given to 220 cases. This mechanical work is a highly important part of the treatment. The hospital has its own shop for the making and fitting of casts and braces; last year more than 2,000 casts were fitted to arms, legs, feet, and backs, and braces were made for 305.

The temper of the children and the attitude of the hospital staff in caring for these deformed unfortunates are matters of great consequence. Food which the boys and girls receive is the best that could be wanted for growing youngsters. Professional care is always tinged with a personal interest from doctors, nurses, and assistants. Clubs and churches over the state give clothing for children whose parents are unable to provide garments of the proper sort; more of this work is needed, and is being done. Any circus will put on a special miniature performance on the hospital grounds to amuse those youngsters who are unable to occupy seats of honor in the big tent. There is nothing in which the children do not have the best of care and attention.

While the work with crippled children is possibly more spectacular than in other departments,

yet digestive disturbances, diseases of all kinds, and problems of nourishment receive attention in the department of pediatrics under the direction of Doctor Byfield, and this clinic may be considered equally important in the large task of caring for the state's children.

Variety of Equipment Necessary

The equipment for pediatrics includes a very complete milk and diet kitchen providing every possible modification of milk. It is furnished with separator, a specially constructed pasteurizer, pressure cooker, sterilizer, fat tester, and other necessary appliances. Milk used in the hospital is tested every day. This department as well as others in the Children's Hospital and the general hospital building is unusually well equipped with research laboratories. One big ward is occupied

Old Capitol. The first capitol of the state of Iowa. Now used for purposes of university administration.

by the babies; two smaller wards are available for older children; and there are units of two and three beds which may be used for patients desiring greater privacy.

In conjunction with the nose and throat department the department of pediatrics seems lately to have discovered one of the causes of deforming rheumatism in children. The clinic has

had opportunity to observe a series of unusual cases resembling pellagra, and a report of the work done and conclusions reached is soon to appear.

The staff has been particularly impressed with the importance of the first few months and years of life, when the influence of heredity is most marked and when the most direct and successful work counter to heredity or in conjunction with it may be done. Dr. Amy Daniels of the Child Welfare Research Station has accomplished some notable work in infant nutrition, conducting experiments with white rats and guinea pigs to prove the nutritive values of food. She has shown that although chemical analysis may indicate food values to be much alike, the difference is often marked. Percentages in the proportion of ingredients for the rats and for infants vary only slightly and the diet for the hospital babies has been much improved as a result of her experiments.

The work of the eye, ear, nose, and throat department with Perkins children is no less important.

Foci of Infection

Perhaps the most interesting achievement in the line of oto-laryngology has been to prove that the foci of infection in crippled children is frequently in the para-nasal sinuses. It has also been demonstrated that nasal sinusitis in children is a very common disease, the best treatment for which is removal of adenoids. All research work in this department is done by the hospital staff, and Dr. L. W. Dean, dean of the college of medicine, is the department head.

Physicians in this clinic are privileged to bring vision to the blind and hearing to the deaf. Operations for cataracts and for other causes to restore sight are ordinary routine, and many a child who came to the hospital with senses impaired or altogether lost has left in full possession of them. In this connection probably the most important work relates to the eyesight of babies just born. Infants who come into the world with infected eyes are rushed to the hospital at once, where they receive the very best of care immediately. This work alone has saved the sight of large numbers of children.

Special Devices Employed

The equipment of the department is worth noting. The audiometer, an instrument for testing tonal range which was developed in the laboratories of the department of psychology of the university, is being put to practical use for the first time in this clinic. It will have a decided influence in the diagnosis of cases in otology. Operat-

ing and laboratory equipment are the best available. The only lacking requisite is space in which to care for all the patients who might be benefited under the law could they come for treatment. In spite of the fact that the general hospital provides nearly 600 beds for cases of all sorts, it is not large enough to handle all the patients who might come under the Perkins and Haskell-Klaus laws alone. In the eye, ear, nose, and throat department there is a waiting list at the present time of more than 150.

Retarded Children Educated

Schooling for the Perkins children has become an important part of the work done at the university. Soon after the Perkins patients began coming to Iowa it was found that older children whose senses were impaired, who had been unable to attend school because of poor health, or who had been kept at home through deformity, were in need of elementary education, and the school was established by the college of education of the university. Children of ten or twelve years, sometimes older, are unable to read and write and must be taught from the very beginning. Because of the variance in age and ability the work has many peculiar phases, and a staff of five teachers is now employed where one was at first sufficient. The boys and girls are greatly helped and upon being dismissed from the hospital many are enabled to enter school for the first time and take up their studies with children of their own age rather than in lower grades.

About 85 or 90 per cent of the cases at the Children's Hospital are treated under the Perkins law. It may be seen, then, of what importance this statute is.

Normal Child Not Neglected

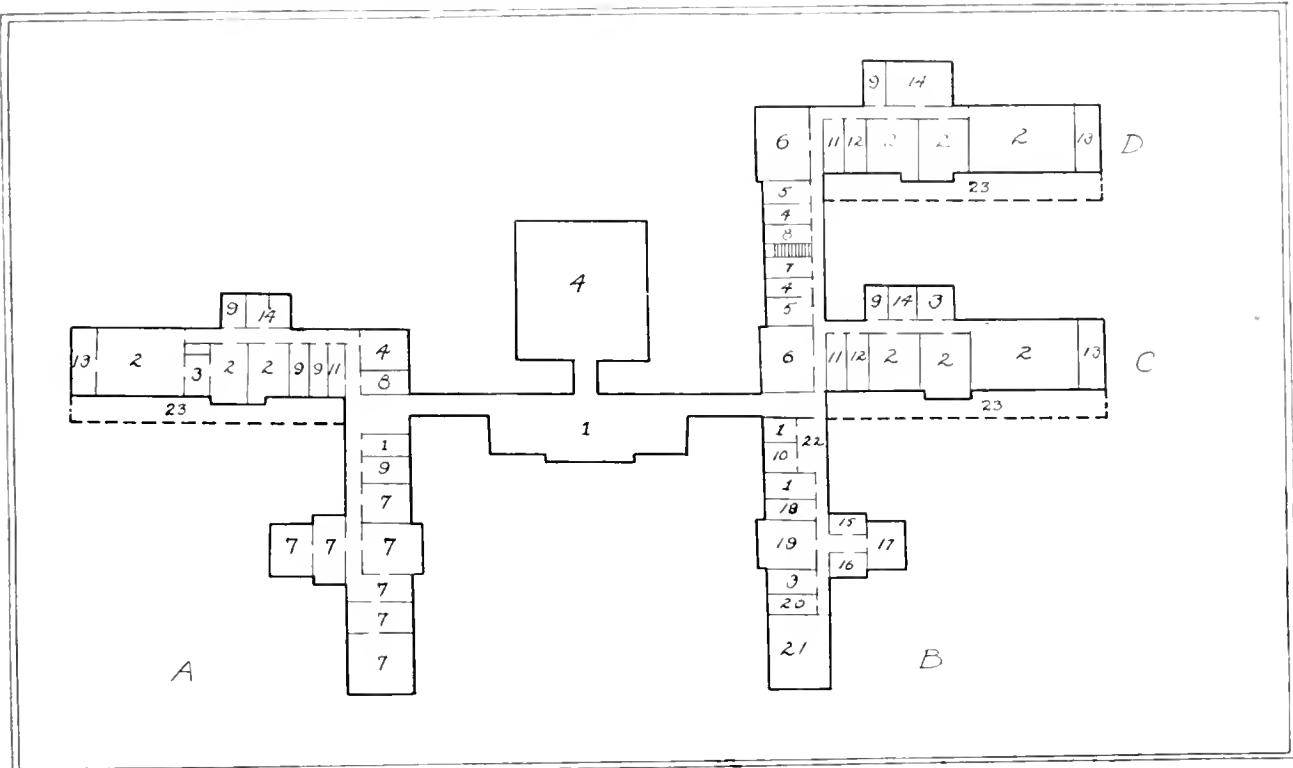

Sick and crippled children are not the only ones for whom the state undertakes medical and research work. In 1917 the state board of education was authorized "to establish and maintain at Iowa City as an integral part of the state University of Iowa the Iowa Child Welfare Research Station having as its objects the best scientific method of conserving and developing the normal child, the dissemination of the information acquired by such investigation, and the training of students for work in such fields."

This work, it should be emphasized, is with children who are normal, or very nearly normal. Investigation is carried on under four main divisions: psychological, nutritive, sociological, and anthropometric; methods used look toward prevention rather than cure. Research has disclosed conditions which aid or hinder growth physically,

mentally, and socially, and the station has undertaken a campaign of education to help parents apply the discoveries made.

Some special work has been done in the problems of speech, particularly in the field of motor coordination, and the station has worked with

comes to Iowa from the University of Pennsylvania hospital in Philadelphia. Mild cases of mental disturbances will be treated in conjunction with the department of psychology, which will take an active interest in the work. Doctor Orton is a member of the university faculty this

Ground plan of the Children's Hospital. Key—(A) Department of Pediatrics; (B) Orthopedic Department; (C) Girl's Wing; (D) Boy's Wing; (1) Offices; (2) Wards; (3) Toilets; (4) Kitchen; (5) Serving Rooms; (6) Dining Rooms; (7) Laboratories; (8) Nurses' Rooms; (9) Private Rooms; (10) Examination Rooms; (11) Isolation Rooms; (12) Quiet Wards; (13) Enclosed Porches; (14) Utility; (15) Sterilizing Room; (16) Surgical Dressing Room; (17) Operating Room; (18) Plaster Bandage Room; (19) Plaster Cast Room; (20) Massage Room; (21) Gymnasium; (22) Waiting Room; (23) Open Concrete Porches.

many children to effect cures or improvement in this field. A course of treatment for mental defects in children has also been mapped out. Vocational guidance is still another field which the research station has entered successfully. In nutrition the department's expert is Dr. Amy Daniels. The results of her work were noted above in relation to their application at the Children's Hospital.

Pamphlets, monographs, and lectures provide means of disseminating information to the people of the state. The facilities afforded for study and the work done are such as to attract graduate students from many colleges and universities, and men and women studying in the station contribute much original research and investigation.

Psychopathic Hospital Projected

Within a year the university hospital is to enter the field of psychiatrics. A new psychopathic hospital is being erected on the west side campus at an expense of \$175,000. The psychopathic work will be in charge of Dr. Samuel T. Orton, who

year and will make visits to the campus at intervals, but the hospital which he is to direct will not be ready until next September at the earliest and work in the department will not be begun until that time. The psychopathic hospital hopes to cure many mild mental cases, prevent others, and make a study of causes which will enable the successful treatment of demented persons.

Free Dental Clinics

Care of the teeth in the clinical infirmary of the college of dentistry is another service the university extends to the people of Iowa. The infirmary is 140 by 60 feet, new and modern, and accommodates 150 dental chairs, equipments, and cabinets. Every set of equipment is provided with connections for water, gas, electricity, compressed air, and drainage. Adjoining the infirmary are an operating room and connecting chambers with full hospital accommodations for oral surgery. All dental work is adequately supervised and the cost of treatment is the cost of material used.

The laboratories of the state board of health, which are located at the university, safeguard the public health in every possible way. Over 22,000 examinations were made during the year ending June 30, 1919. Examinations for the purpose of diagnosing diseases were: 8,830 for diphtheria; 2,630 for tuberculosis; 1,934 for typhoid fever; 22 for rabies; and the rest miscellaneous. In the first year's work in the Wassermann division, where tests are made for venereal diseases, 4,687 examinations were made. In taking analyses of water 1,879 samples were examined during the year. The Pasteur treatment for rabies was administered to eight patients, each of whom received twenty-five treatments. A state epidemiologist, whose duties are to prevent outbreaks of disease and curb them in the best possible way when they occur, is stationed at the university, his work being in close connection with the board of health. He acts in matters of sanitation and makes inspections and examinations to determine the possible presence of disease.

Campaign of Health Education

Finally, through the extension division of the university a campaign of health education is conducted among the people of the state. In some ways the work is done personally; more often it takes the form of bulletins and pamphlets.

This year for the first time extension work in the interests of the Perkins children is being undertaken. A registered nurse, who is also a trained social worker, visits the boys and girls in their homes to give health education, to see that advice prescribed by the hospital doctors is followed, and make certain that the children are being educated in a manner which will link up with instruction given at the hospital school. Environment of the children is considered as well as medical needs, and the nurse sees that proper home life is afforded. When children are not receiving proper nutrition, a charitable agency or public health service is enlisted to provide proper food if the families are too poor to afford the right kind of nourishment. When further hospital care is found advisable the nurse recommends that the child be returned for further treatment.

Work in the field of rural sanitation and hygiene will be done this year by a former army expert. Details remain to be worked out.

Education through bulletins is to be on a larger scale than ever before, and the field of nutrition will be particularly emphasized. Much attention will be given to publications and bulletins on the prenatal care of the mother. The whole subject of child welfare, dealing particularly with

mothers and infants, will be covered. Some bulletins will also be published for the benefit of physicians, this material to be sent only on request. Research will be the only field of child welfare which the extension division will not touch.

If the university is to be of greatest service the work can not end within its four walls, since the problem of health lies in prevention as well as in curing diseases and ailments. The University of Iowa seeks to expand its facilities for education, and in this manner perform a service as important as in providing medical treatment.

GOVERNMENT WANTS WORKERS IN VENEREAL DISEASE CAMPAIGN

The recently created Interdepartmental Social Hygiene Board of the United States Government is in need of a number of specially trained men and women to complete its organization. The United States Civil Service Commission has announced examinations for the following positions: Chief of division for scientific research, \$3,500 to \$4,500 a year; chief of division for educational research and development, \$3,500 to \$4,500 a year; educational assistant, \$2,800 to \$3,600 a year; chief of division of relations with States, \$3,500 to \$4,500 a year; chief of division of records, information and planning, \$3,500 to \$4,500 a year; supervising assistant and inspector, \$2,800 to \$3,600 a year; field agent, \$1,800 to \$3,000 a year. All positions are open to both men and women. Detailed information and application blanks may be obtained from the United States Civil Service Commission, Washington, D. C., or from the secretary of the United States Civil Service Board at the post office or customhouse in any of 3,000 cities.

PREPARING FOR RECURRING INFLUENZA EPIDEMIC IN 1919-20

In response to widespread questioning by the public and physicians, the United States Public Health Service has prepared a statement in which are presented the accepted facts and probabilities as to whether a recurrence of the 1918 influenza epidemic may be expected in the coming winter.

Probably, but by no means certainly, there will be a recurrence of the influenza epidemic this year.

Indications are, that should it occur, it will not be as severe as the pandemic of the previous winter.

City officials, state and city boards of health, should be prepared in the event of a recurrence.

The fact that a previous attack brings immunity in a certain percentage of cases should allay fear on the part of those afflicted in the previous epidemic.

Influenza is spread by direct and indirect contact.

It is not yet certain that the germ has been isolated, or discovered, and as a consequence there is yet no positive preventive, except the enforcement of rigid rules of sanitation and the avoidance of personal contact.

A close relation between the influenza pandemic and the constantly increasing pneumonia mortality rate prior to the Fall of 1918 is recognized.

It is now believed that the disease was pretty widely disseminated throughout the country before it was recognized in its epidemic state. This failure to recognize the early cases appears to have largely been due to the fact that every interest was then centered on the war.

MEDICAL EXTENSION WORK

BY DON K. MARTIN, EXECUTIVE SECRETARY, OHIO STATE MEDICAL ASSOCIATION, COLUMBUS, OHIO

WITH a realization that the scientific practice of medicine requires constant specialized study the Ohio State Medical Association, through its Committee on Medical Education, has for the past four years held annual series of post-graduate lecture courses on medical subjects throughout the state in order to inform the general practitioners on the latest methods in diagnosis and treatment. This system, which was inaugurated in 1916, took into account the impossibility on the part of most physicians to devote the time or the expense necessary to attend medical universities from time to time to learn of the more recent advances in the scientific practice of the profession. The Committee on Medical Education was inaugurated that year and has steadily increased the interest on the part of the profession in the group meetings which are held each summer and autumn.

Meetings in Accessible Centers

These meetings are planned months in advance and are held in from twelve to fifteen of the most accessible centers of population throughout the state. Each season a definite subject is treated, such as fractures, obstetrics, and physical diagnosis; and this year a resumé of venereal diseases is being presented by a specialist who was head of the Bureau of Venereal Diseases for the state of Ohio during the war period.

In selecting the lecturers the committee is careful to find not only a member of the profession who is well known throughout the state, but one who through the practice of his particular phase of medicine is in possession of specialized information in that particular branch, broader than it is possible for the general practitioner to attain.

Motion Pictures Are Used

When possible and convenient, these group meetings are combined as a part of the program for annual district meetings and usually are held in the late summer, thus avoiding the extreme hot weather, and just prior to the start of the fall college year to enable the lecturers, who are in most cases instructors in medical schools, to devote the necessary amount of time to the program. Many of the lectures are graphically illustrated by motion pictures and lantern slides and in some cases, where material is available, clinics are held. Each meeting comprises the greater part of one day and evening, and is usually divided into three sessions, possibly including a luncheon or dinner

as a social feature. At a number of these meetings as many as 60 per cent of the physicians in the six or eight counties included are in attendance.

In order to coordinate the work in arranging the series of meetings, the headquarters of the State Medical Association handles all the details including the series of announcements to the individual members of the profession, and the newspaper stories. Local plans are placed usually in the hands of the president or secretary of the county medical society where the particular meeting is scheduled.

Some of the Lecturers

Among those who have given of their time and talents in this work, as lecturers, are Dr. Charles Edwin Briggs, Cleveland; associate professor of surgery, Western Reserve University School of Medicine; Dr. William D. Porter, Cincinnati, clinical professor of obstetrics, Medical Department, University of Cincinnati; Dr. Charles F. Hoover, Cleveland, professor of medicine, Western Reserve University School of Medicine, and Dr. Harold N. Cole, Cleveland, assistant professor, dermatology and syphilis, Western Reserve University School of Medicine.

The policy of the Ohio State Medical Association is indicated in the attitude that it is not only the duty of the organized profession to constantly raise the standards of practice and stimulate research and information in the science, but to exert its full efforts in sickness-prevention movements. In this connection the Committee on Control of Cancer, of the Association, cooperating with the Committee on Medical Education, is completing plans for a state-wide campaign of information, first to the profession, and then the education of the public in preventive measures. The Association also was largely responsible in the public campaign of education against tuberculosis and with the organization some years ago of the Ohio Society for the Prevention of Tuberculosis.

Medical Association of the Southwest

The Medical Association of the Southwest holds its fourteenth annual meeting at Oklahoma City, Okla., October 6, 7 and 8. The gathering has been planned to take the form of a welcoming home for the medical officers of the army in the Association membership. Those participating in the program and discussions include the health officers from various health departments of the state.

HOSPITAL ASSEMBLY GIVES ATTENTION TO PUBLIC HEALTH ISSUES

Many significant and valuable suggestions as to methods by which a closer cooperation of hospitals and other public health agencies may be secured were brought to the attention of delegates in attendance at the twenty-first annual convention of the American Hospital Association, during the gathering held at Cincinnati in the second week of September.

The American Hospital Conference held sessions simultaneously and adopted a constitution wherein the name of the Conference is changed to the American Conference on Hospital Service. The American Dietetic Association held its second annual convention in conjunction with the conferences of the two hospital organizations.

Dr. A. H. Warner, president of the American Hospital Association, in his presidential address, proposed that the American Hospital Association turn its attention to the development of state and sectional hospital associations which would be affiliated with the national body.

Common to the discussions of each of the three organizations was the problem of training courses and facilities for the education of professional workers in practically all departments of hospital administration.

A review of the proceedings and reports of the three groups brings to attention several questions affecting the relations of hospitals and the public health departments and welfare agencies. Of main importance from this standpoint are the problems of hospital standardization and matters that are the subject of legislation in various states.

The report of the legislative committee of the American Hospital Association, which is intended to give a brief account of the activities of the committee during the past year, seeks to emphasize the importance of the relations between Federal and state governments and the hospitals, as well as the necessity for organized effort on the part of the hospitals to strengthen and further improve these relations. For the protection of the public health and the financial and other interests of the hospitals it demands organized legislative action.

The report summarizes, to some extent, the opinions voiced from the convention floor on the subjects of public health and legislation. Some interesting excerpts from the report are here quoted:

"All hospitals, whether public or private, have certain relations to departments of state. They are sometimes subject to certain rules and regulations made by state departments, and often bound by laws of supervision or control at the hands of the state. The laws, rules and regulations governing such relations are not alike in any two states. It may very properly be said of the plan of supervision and control of hospitals by state governments: 'Mediocre, what there is of it, and, a lot of it, such as it is'

"During the year the committee has sought to become informed, so far as possible, of the exact relations between hospitals and the state governments. Much data has been gathered, and some analyses made of it. It warrants the conclusion that there is work to be done in this direction by the organized hospitals. They must take up these matters in each state, and straighten them out. The association can help to pave the way."

The committee warns that the hospitals of every state will be vitally affected by whatever form of legislation that may be adopted to enforce the Federal prohibition law. They are concerned regardless of opinions on the merits of the prohibition. Says the report: "If hospitals

are to be permitted to dispense distilled spirits and wine for medical purposes under national prohibition, iniquitous regulations, similar to those of the Harrison Act, may well be anticipated. But, the hospitals are more concerned from another angle—namely, patent medicines."

Attention is called to the fact that in one state at least, which has adopted state prohibition, the dry enforcement bill was written in the special interests of the patent medicine manufacturers to the detriment of public health. A repetition is possible in Congress, the report warns, if the dry enforcement regulations are unwisely made.

The following officers were elected for next year: President, Dr. Joseph B. Howland, superintendent Peter Bent Brigham Hospital, Boston; president-elect, Dr. Louis R. Baldwin, superintendent University Hospital, Minneapolis, Minn.; first vice-president, Mr. H. E. Webster, superintendent Royal Victoria Hospital, Montreal, Canada; second vice-president, Dr. R. G. Brodrick, superintendent San Francisco Hospital, San Francisco, Cal.; third vice-president, Miss Margaret Rogers, superintendent Jewish Hospital, St. Louis; treasurer, Mr. Asa S. Bacon, superintendent Presbyterian Hospital, Chicago; trustee for one year, Dr. Louis H. Burlingham, Barnes Hospital, St. Louis; trustee for two years, Dr. Andrew R. Warner, superintendent Lakeside Hospital, Cleveland; trustee for three years, Rev. Maurice F. Griffin, St. Elizabeth Hospital, Youngstown, Ohio, and vice-president of the Catholic Hospital Association; trustee for three years, Mr. Richard P. Borden, Union Hospital, Fall River.

It was voted that the convention should meet next year in Montreal, Canada, the time to be either during the latter half of September or the first half of October.

The American Conference on Hospital Service postponed the election of a president until the man most qualified for the office can be found.

The officers elected, with the exception of president, who, as already indicated, will be selected later, are: First vice-president, A. R. Warner, M.D., superintendent Lakeside Hospital, Cleveland (American Hospital Association); second vice-president, Miss Clara D. Noyes, Bureau of Nursing, American Red Cross (American Nurses Association); treasurer, Harry E. Mock, M.D., Chicago, American Association of Industrial Physicians and Surgeons; trustees, for three years, Dr. S. S. Goldwater, Mount Sinai Hospital, New York City (American Hospital Association); Dr. John G. Bowman, Chicago (American College of Surgeons); Dr. John M. Dodson, dean Rush Medical College (American Medical Association); trustees, for two years, Father Charles B. Moulinier, Marquette College, Milwaukee (Catholic Hospital Association of United States and Canada); Miss Edna G. Henry, Social Service Department, Robert W. Long Hospital, Indianapolis, Ind. (American Association of Hospital Social Workers); Dr. Roger Morris, Association of American Medical Colleges, University of Cincinnati Medical School; trustees, for one year, Col. James D. Glennan, Medical Department, United States Army; Dr. David S. Strickler, Denver, Colo., Federation of State Medical Boards of United States; Senior-Surgeon J. H. White, Medical Department of United States Public Health Service.

The next meeting of the Hospital Conference will be held in Chicago during the first week of March, 1920. The delegates favored the limiting of work undertaken for the present to three or four definite problems. Committees were chosen to pursue investigations in the fields so outlined, which are the Intern Problem, the Nursing Problem, Standardization of Hospital Service, and the Medical Aspects of Social Insurance.

MEDICINE AND INDUSTRY

Hygiene, Sanitation, Medical and Hospital Service in Relation to Industry

OTTO P. GEIER, M. D., *Editor*

THE COST OF LIVING VS. THE HIGH COST OF DYING

THE high cost of living is in the minds and on the lips of every one. The press is daily giving screaming headlines to this or that angle of the subject. Grand juries are busy indicting profiteers first in this and then in that city. The temperatures of cold storage-house owners are fluctuating rapidly with each new public revelation. The Attorney General of the United States has asked Congress for an expense account of \$50,000 a day to bring the malefactors to justice. The Railroad Brotherhoods have given the government the alternative of reducing the cost of living or raising the wages of its members. The economists, on their part, are crying for more production to offset increased costs.

The high cost of dying, on the other hand, lingering or acute illness, and injury, is not receiving such notice. Discussions of certain phases of the general subject, as promoted by the proponents of health insurance, have languished with the adjournment of state legislatures. And yet the high cost of dying, unlike that of the high cost of living, is a permanent question; it is in no way less complicated and is perhaps more far-reaching in its economic and social effects. The President, his Attorney General, Congress, state and municipal attorneys, professors of political science, the press, and the pulpit—all are contributing their share to the vexing problem of reducing living costs. The whole rumpus, extending over months, has brought a reduction of a few per cent in costs. All power and good staying qualities to this goodly brand of reformers!

In comparison, how feeble have been the efforts, how small the crowd of those who are seriously engaged with reduction of the unnecessary high cost of illness by some definite state and federal plan of organized curative and preventive medicine.

Relatively, the science of medicine has advanced rapidly enough, but its organized applica-

cation to the people as a whole is decades behind research both for preventive and curative medicine. It is proverbial that only the rich and the very poor receive the best that the medical profession and its allied professions have to offer. How this condition may be altered, how medicine and surgery in its best form may be made accessible to the great middle class, the backbone of the nation, is yet unanswered.

Many studies have been made as to the average costs per family of medical attention, some of which include dental, nursing, and hospital costs. A fair deduction to be made from these surveys is that at least 5 per cent of the income of each family would on the average be required to meet the combined costs of all curative medical service as it now obtains. Apparently no one with authority has yet formulated a plan nor estimated the costs of an adequate medical service of diagnostic and curative nature.

The only discussions that have seemed to border on the question in hand have been those stimulated by the proponents of health insurance, whose main energies, however, are given to setting forth the advantages of distributing the financial burden of illness by some state-wide compulsory payment of insurance premiums. Little or no attention or interest has been excited in the all important question as to how the quality of medical, surgical, nursing, dental, hospital, and diagnostic clinical service may be raised; how the number of units of such service may be increased so as to meet the greater demand; and, finally, how such service may best be made available to all. To deny that these are all important in any plan for health betterment, to fail to include these in the fundamental structure of any health insurance plan, is proving false to the trust of the public, whose hopes are being raised by the glowing promises for social justice therein.

One ray of hope that some such thoroughly balanced, positive, creative health program may receive consideration lies in the conference of wide scope that was called into being by the

American Public Health Association. The other ray of hope, that curative medicine in all its aspects may be squared with the problem of health insurance, comes from the appointment of a committee by the recently organized American Hospital Conference to study this subject. Whatever is promising in this latter direction comes of the fact that membership in this association is comprised of some fifteen national organizations,¹ all having to do with the science of disease and its cure. The members of such a committee could hardly hope that any narrow individualistic opinions would be tolerated or survive. Their deliberations would be national in scope, and could include every social economic and scientific phase of the subject. Theory of reform would be met by practical experience with some promise that a workable and acceptable solution would be found.

These component national associations have each in turn been attempting to standardize their practices. When by a series of conferences they have conscientiously fitted the results of their studies, one to the other, into one harmonious scheme of organization for the care and cure of the sick, then the public may know that a plan for health insurance evolved out of the rich experience of all these associations is safe, sound, and worth any sums of money required for its provisions. Such a plan would be democratic in origin; it would receive universal support at the outset and would contribute immeasurably to the welfare of the people. Inasmuch as it would greatly reduce unnecessary sickness and suffering, it could add materially to national productivity. In the sense that it could add to production such a plan could also reduce the high cost of living.

LABOR LEGISLATION REVIEW URGES COMPULSORY HEALTH INSURANCE

The story of the New York campaign for health insurance, the text of the new state health insurance law, and an introductory note by John B. Andrews, secretary of the American Association for Labor Legislation, in support of compulsory health insurance as one of the mediums through which the nation may avert social disorder and violence, appear in the June issue of the *American Labor Legislation Review*. Rehabilitation for industrial cripples is declared a proper matter for congressional action. Mary MacArthur, general secretary of the British Women's Trade Union League, is the author of a paper

entitled "American Health Insurance Bill Better Than British Act," Margaret Bondfield, assistant secretary of the National Federation of Women Workers of Great Britain, declares that "Social insurance, if it is to be economically conducted for the benefit of all those who are in greatest need of this protection, must be universal, that is, compulsory in form."

CINCINNATI ORGANIZES SAFETY COUNCIL

The National Safety Council announces that a Local Safety Council has recently been organized in Cincinnati. Although this new local will conduct all of the activities usually carried on by similar organizations in other cities, it is unique in that it is closely affiliated with the College of Medicine of the University of Cincinnati.

This college has instituted a Department of Industrial Medicine and Public Health, the purpose of which is to offer special courses for the training of industrial physicians and surgeons. In connection with the regular medical courses the student will be given instruction in industrial medicine, shop sanitation, occupational hazards and diseases, labor economics, labor conditions and problems, industrial relations, accident prevention and employment. The special courses are being financed by the manufacturers of Cincinnati.

The staff comprises a medical director, a woman sanitarian to work with the women employed in industrial occupations, a full-time employment and industrial relations man, and a full-time safety engineer. The employment and industrial relations man will act as secretary of the local Employment Managers' Association and the safety engineer will act as secretary of the local council of the National Safety Council. Both will assist in teaching the special industrial-medical courses and in directing the laboratory and field work to be done by the students. Half of the student's time will be spent in the industries and half in the University.

Extension Course in Accident Prevention

The staff will not only instruct physicians in safety, employment, and industrial relations and give them degrees or certificates after completion of the course, but will also conduct extension courses in accident prevention and employment management. It is expected that the students in the cooperative engineering course at the University, as well as persons employed in the industries, will take advantage of the opportunities afforded.

Mr. G. H. McLain, formerly safety engineer and assistant to the supervisor of labor at the Dayton Electrical Company, Dayton, Ohio, has been appointed secretary of the Cincinnati Local Safety Council. Mr. McLain is a graduate of Purdue University, where he received special industrial training. He has taught industrial courses in high schools and normal schools for a period of five years, and spent five years as a traveling salesman selling machine tools. By education, experience and personality Mr. McLain is well qualified for the secretaryship of this new local council, which, because of its affiliation with the University and its activities in public service, requires an unusual combination of qualities and talent.

The General Electric Company recently established a dental clinic for the employees at the company's works in Schenectady, N. Y. Free examination and advice is given, and minor treatments are done by the company dentist. Employees suffering from acute troubles are advised to consult their family dentist.

1. These organizations are: American Association of Industrial Physicians and Surgeons; American Association of Hospital Social Service Workers; American College of Surgeons; American Hospital Association; American Medical Association; American Nurses Association; Association of American Medical Colleges; Catholic Hospital Association of the United States and Canada; Federation of State Medical Boards of the United States; International Compensation Board; Medical Department of the United States Army; Medical Department of the United States Navy; National League of Nursing Education; National Organization for Public Health Nursing; and the United States Public Health Service.

MEDICAL AND HOSPITAL TREATMENT UNDER UNITED STATES COMPENSATION ACT

BY JOHN W. TRASK, SURGEON, UNITED STATES PUBLIC HEALTH SERVICE, MEDICAL DIRECTOR, UNITED STATES EMPLOYEES' COMPENSATION COMMISSION

THE furnishing of adequate medical and hospital treatment for injured government employees under the Compensation Act has offered certain difficulties. Some of the difficulties have been due to the status of the practice of medicine, others to the conditions of hospital management.

The benefits provided by the United States Employees' Compensation Act to employees of the Government injured

in the performance of duty are: (1) Medical and hospital treatment. (2) Money compensation for loss of wages in excess of three days. (3) Money compensation to the surviving dependents of employees dying as a result of injuries.

Employees injured, even though the injuries be slight and cause no interruption of work, are entitled to treatment for the injuries if there is any need for it. Only those are entitled to compensation whose injuries cause an absence from work in excess of three days. Naturally, therefore, the number who receive medical benefits under the Act is much greater than the number who receive money compensation for time lost.

Provisions of the Law

The principal section of the Law relating to medical treatment and hospital service is Section 9, reading as follows:

That immediately after an injury sustained by an employee while in the performance of his duty, whether or not disability has arisen, and for a reasonable time thereafter, the United States shall furnish to such employee reasonable medical, surgical, and hospital services and supplies unless he refuses to accept them. Such services and supplies shall be furnished by United States medical officers and hospitals, but where this is not practicable shall be furnished by private physicians and hospitals designated or approved by the Commission and paid for from the employees' compensation fund. If necessary for the securing of proper medical, surgical, and hospital treatment, the employee, in the discretion of the Commission, may be furnished transportation at the expense of the employees' compensation fund.

WHAT IS REASONABLE SERVICE?

The problems involved in securing proper and adequate medical attendance for government employees are of particular interest to all who are concerned in furnishing hospital benefits to large numbers of employees.

The Commission found it could not afford the services of any but the most competent physicians available.

Uniformity of fee schedules, and uniformity of practice are impracticable. The best service and the cheapest is that best adapted to the individual case, the objective being the quickest and completest possible restoration of function.

The Law provides what may be considered unlimited medical service, that is, it provides that medical service for an injury shall be furnished for a reasonable time after the injury. As a reasonable time will be as long as the injured person has need of treatment on account of the injury, the service is coexistent with the need thereof.

The provision that the medical and hospital service furnished shall

be reasonable limits it to that which may properly be considered to be effective in bringing about the restoration of damage done by the injury, that is, the restoration in so far as possible of the injured person to the physical condition possessed by him previous to the injury. This implies efficiency of the service rendered.

The Law further provides that United States medical officers and hospitals shall be the medium through which treatment shall be furnished, but that where it is not practicable to secure the desired medical and hospital service from United States medical officers or hospitals, then it shall be furnished by private physicians and hospitals designated by the Compensation Commission.

Distribution of Beneficiaries

Government employees are at work in all inhabited portions of the country, and in a measure in the uninhabited portions as well. In addition to the 105,000 civil employees of the executive departments and legislative branch of the Government in the District of Columbia, there are the hundreds of thousands of employees of the departments scattered throughout the country. The Treasury Department has its Customs Service at ports and at points on the international boundaries. It has its mints. The War Department has its arsenals which are large industrial establishments employing many thousands, its quartermaster depots and other establishments. The

Navy Department has its navy yards which are similarly large industrial plants. The Department of Agriculture has its agents and workers in all parts of the country. The Department of the Interior has its employees. Then there are the employees of the United States Courts and those of the Post Office Department with its post office clerks and carriers in every city, town, and hamlet, and its rural letter carriers covering the country as with a net work, aggregating in all several hundred thousand.

As most injuries are of an emergency nature and require immediate treatment, if at all, and as United States hospitals and medical officers have a relatively limited distribution, the purpose and need of designating physicians and hospitals is apparent.

The War Department has met the emergency medical needs at its arsenals, and principal ordnance plants and supply depots by furnishing dispensary service. The Navy has likewise cooperated by furnishing dispensary service for injured employees at its navy yards. The United States Public Health Service has cooperated by making freely available to all beneficiaries of the Compensation Act its hospitals and dispensaries, wherever located. The expansion of the facilities of this service, because of its needs in connection with the treatment of the discharged soldiers and sailors, beneficiaries of the War Risk Insurance Act, is making available increasing medical and hospital facilities also for the beneficiaries of the Compensation Act.

Problem of Caring for Large Numbers

The attempt of the Commission to supply efficient medical and hospital service has brought out clearly a number of facts of particular interest to those in any way interested in the furnishing of hospital benefits to large numbers of employees. The idea was first held that the necessary medical, surgical, and hospital service for injured employees could be best obtained wherever Government hospitals and dispensaries were not available by the designation and use of hospitals, as it was believed that the hospital represented group medicine; that the injured employees could be sent to the hospitals and there would receive the attention of whatever specialist the nature of their various injuries indicated, be it the general surgeon, orthopedic surgeon, ophthalmologist, neurologist, roentgenologist, pathologist, or bacteriologist; that the question of medical and surgical treatment could be left to the hospital; and that only where there was no Government hospital or dispensary, or private hospital would there be need of designating private physicians.

The Commission, however, early found that leaving the question of medical and surgical treatment to the hospital was not a practicable arrangement; that the hospital service as relates to bed, board, and nursing was in most city hospitals a thing quite apart from the furnishing of the efficient medical and surgical attention implied by the Federal Compensation Act. Patients sent to hospitals were frequently given scant consideration. If assigned to a particular physician, it was often to one of lesser experience. Often the cases seemed to be left entirely to the inadequate attention of the busy resident staff. This was true in general, excepting in the proprietary hospitals in the smaller towns. It was true of even the better hospitals, one might say of the best hospitals, of the larger cities.

Some Difficulties Encountered

The difficulties encountered in sending injured employees to hospitals for treatment, instead of to selected surgeons, is illustrated by the case of M. M., an employee of the Brooklyn Navy Yard, who sustained a fracture of the clavicle while working on the dry dock, Thursday, May 29, 1919, at 10:30 p.m. He was taken in the naval ambulance to a hospital, where he remained until 2:00 a.m. before being assigned to a ward. The patient states in a letter of June 27 that Friday morning, the day after the injury:

A doctor came around and looked at me and went away. That's all I saw of a doctor that day. In the afternoon my shoulder began to swell and get black. Saturday morning, May 31, another doctor came, also looked at me and also went away. Between two and three o'clock that afternoon a doctor came and set my shoulder in a rough manner, not half bandaging it to keep it in place. Sunday morning the bandages became loose. A doctor came and promised he would fix the bandages within a half hour, but did not show up that day. A doctor came around and said that he would like to have an x-ray picture taken of my shoulder on Monday morning. Monday morning the doctor came and promised to re-fix my bandages, but did not do so. I asked him if he were going to have an x-ray picture taken, but he said no. Nurse came around, said I was to be discharged the next day, Tuesday. Tuesday morning a doctor came around and fixed the bandages in a rough manner. I was let lie there from Thursday night to Tuesday without proper treatment. Saturday morning they gave me a dose of salts and let me lie there in bed without any covering to go to toilet until half past one in the afternoon, which left me in agony. When I was discharged my shoulder was still out of place and it is still not in place.

Results Depend on Management

The following illustration is cited as being one of a type not uncommon in the experience of the Commission in sending its beneficiaries to hospitals. The point of view of the hospital in this case was more or less typical of hospital manage-

ment, and perhaps, under existing conditions, was in a measure justified. The patient in this case sustained a fracture of the *os calcis*, with other injuries of the right foot and, as a result, developed rigid flat-foot. There was also an injury of the left foot, at least a sprain, probably also a fracture, but the exact nature of it was never determined.

June 1, 1918, H. W., aged 37 years, helper on a Government truck, was thrown from the truck in a collision with a freight car at a crossing. He landed on his feet, "injuring both ankles." An ambulance was summoned and the patient was taken to one of the well known hospitals in New York City. On June 4 he wrote the Commission as follows:

In reference to the way I was sent home from the hospital Saturday, June 1, I beg to say these are the words the doctor said to me: "I will bandage your ankle so you will be able to walk. How are you going to get home?" I said: "I don't know." Then he said: "If you lived in this district, I would send you home in the ambulance." When I saw they did not want me there, I said, "Well, lend me a pair of crutches and I will manage to get home."

Naturally, the man, on going home under these conditions, sent for his family physician under whose care he remained until August 13, when he applied to a United States Public Health Service Hospital for treatment, and the nature of his injury was determined and such treatment given as offered best hopes of beneficial results in consideration of the length of time that had elapsed since the injury was sustained. The man was unable to go back to work until January 14, 1919, and he will probably carry through life a greater disability than would have resulted if expert treatment could have been obtained from the beginning.

A Hospital Viewpoint

As the injury was a rather serious one, the Commission wrote as follows to the superintendent of the hospital to ascertain why the case had not received adequate attention and treatment:

There is enclosed herewith a copy of a letter received from one H. W., dated June 4, 1918, also copy of our reply. Mr. W. was a civil employee of the Quartermaster Department, U.S.A., and was a beneficiary of the Federal Compensation Act because of his injury. Pursuant to the provisions of Section 9 of the Compensation Act, copy enclosed, your hospital was designated as a hospital for the care of these beneficiaries. The nature of the treatment furnished by you in this case and the atten-

tion given to the injured employee are not as complete or as considerate as the Commission purposes to furnish to injured employees. The point of view of the hospital toward these cases seems to be somewhat different from that of this Commission. Kindly advise the Commission whether the manner in which this case was handled represents the policy of the hospital, or whether it was simply

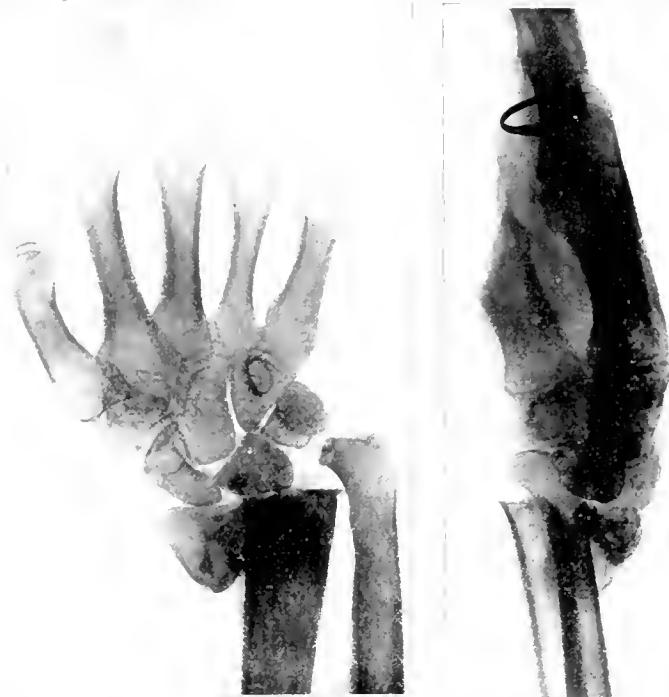

Fig. 1.—At the left is shown an X-ray photograph taken twelve months after the injury was sustained. Shows dislocation and malposition of parts due to inexpert and careless treatment. The result is a permanent cripple. At the right is a photograph of the same injury giving a lateral view of the parts.

an occurrence that will sometimes happen in a busy institution.

The reply from the hospital was as follows:

In reply to your letter of August 23, 1918, we beg to state that Mr. W.'s complaint is entirely unjustified. For a young, healthy, able bodied man like Mr. W., at this particular time, when it is of the utmost importance to conserve every resource, to demand the time of doctors and nurses in our wards to look after sprained ankles, is, in our estimation, something to be very much ashamed of and decidedly unpatriotic.

If the patient were a boy of 14 or 15 years old, an elderly man, or a sick man, we would not have permitted him to leave the hospital alone if we were obliged to engage a taxicab at our own expense.

There is nothing in the Federal compensation law that we can construe as authority to transport patients from the hospital at your expense and, even if we did have such authority, we would use discretion about exercising it in the case of a patient like Mr. W.

Now in regard to the third paragraph of your letter, we are going to be very frank about answering it, as we are anxious to avoid misunderstandings and to save your time as well as our own in reference to complaints of this character. In the first place, every case that comes to this hospital is examined by a competent doctor, and sometimes by more than one when it is necessary, and if you delegate us to look after your employees we think it

is only fair to request that you place some confidence in us rather than too much in the statements of your employees.

Hereafter, every patient that is sent in from your department is going to be reported to his superior officer immediately after examination, and we are going to state the diagnosis, treatment necessary, and probable length of disability. We have found several patients from your department whom we think were malingeringers. The majority of the people you have sent us were suffering from strains, contusions, and sprains,—most of them slight. These are very difficult conditions to treat if a patient is inclined to malinger because there is little or no treatment necessary, and there is no reason why a patient should become dissatisfied because a doctor doesn't spend an hour in finding out that he has a slight contusion of the ankle.

We have done everything possible to cooperate with the War Department, and it has been our policy to discourage patients from discontinuing work and coming to the hospital for unnecessary treatment. We do not have much trouble with employees of private companies because there is a clause in the New York state law which provides that the patient must be disabled for two weeks before he can collect his wages unless his injury is severe enough to disable him for seven weeks.

If you find at any time that there is negligence on the part of our doctors, nurses, or clerks, please report it immediately, as we do not want anyone coming to the hospital to receive improper treatment, and if they do we want to be informed about it.

We appreciate the rigid investigation you have made, and trust that our explanation will give you a better understanding of our position.

Diagnostic Facilities Must Be Adequate

At the time of writing the above letter the hospital had not been advised of the serious nature of the injury in this case. In the experience of the Commission fracture of the *os calcis* is a serious injury, demanding expert treatment; in fact, it finds that many so-called sprains are complicated by fractures and are liable to cause disability for many kinds of work for considerable periods of time. Also, the Commission has, during the last two years, found few cases of actual malingeringers among its beneficiaries. It has, however, had a considerable number of cases believed for a time to be malingeringers due to the limitations of available diagnostic facilities.

The hospital management was sincere, and was attempting to render adequate service. Hospitals are not to be criticised for failure to make proper diagnoses and recognize the true nature of injuries. Diagnosis requires experience, time, and interest in the case to a greater degree than can properly be expected under existing conditions in most hospitals. The only solution seemed to the Commission to be the treatment of cases in hospitals, but as patients of selected surgeons. The following case illustrates the difficulties of diagnosis even by physicians of considerable training. The condition overlooked was fracture of the vertebrae, a condition frequently not recognized.

Delayed Diagnosis Prevents Treatment

On December 5, 1917, F. G., a carpenter, aged 57 years, employed by the United States, on a vessel at Montreal, Canada, fell a distance of about twenty feet into the hold of the vessel and received various injuries. He was taken to a hospital in an unconscious condition.

The diagnosis was "laceration of scalp, fractured skull, injuries to back." Spinal puncture revealed blood in cerebrospinal fluid. He was unconscious for four weeks. Then he began to improve slowly and was gradually able to use his limbs. With the return of consciousness he was found to be irrational, acting like a child, and to have partial paralysis of the legs. February 5, 1918, he left the hospital. At home, while under the care of his family physician, he gradually recovered the use of his legs and his mental condition slowly improved, but he continued to complain much of the severe pains in his back. On July 27, 1918, arrangements were made to have him examined by a medical officer at Montreal whose report was as follows:

F. G., male, aged 57, carpenter in the employment of the United States Shipping Board, injured December 5, 1917.

Present General Condition.—Good except that he complains of pain in the lumbar region and walks rather slowly, with body slightly bent forward. No apparent mental defect. Skin and sclera clear; pupils normal and react to light; nystagmus and Romberg's sign absent. Patellar reflexes normal. Urine free, specific gravity, 1,020, color straw, no albumin or sugar. No tenderness or deformity of spine or back.

Character and Extent of the Injuries.—At the present time none, except that he walks rather slowly with body bent slightly forward, and he complains of a constant dull, aching pain in the lumbar region. The pains are more acute at times but are slowly improving. He has not been able to do any work since his discharge from the hospital, but he said if he were relieved of the pain in his back he would be able to resume his work. He is afflicted with left inguinal hernia of twenty-five years' duration.

Objective and Subjective Symptoms.—None, except the slow walk and lumbar pains as above described.

On October 29, 1918, the case was sent to another medical officer at Montreal for examination. He reported:

Since leaving the hospital the patient has been under the care of a private physician. Spends his time around the house, going out only to church or to the store. Says he can not walk more than a quarter of a mile without getting tired out. He appears to be a well nourished individual with flabby muscles, and emotional at times.

Mental Attitude.—Talks intelligently; appears to be oriented, but the friend who accompanied his wife and himself to the office, said that his mind was affected in that his memory was poor.

Physical Examination.—Muscular coordination good; reflexes normal. Knee jerks present. Eye reacts to light and accommodation. Movement of joints of upper and lower extremities, free. Movements of spine free; bending forward, backward, lateral, and rotation good.

Complains of pain when the spine from the eighth to the twelfth thoracic vertebrae are tapped lightly. Refers the pain to the loins. In rising from a chair his movements are slow, and he assists himself by catching hold of the arms of the chair. There is a large inguinal hernia present on the left side; a smaller one on the right. Does not know when they occurred, but thinks probably at the time of the accident.

He has a scar on the back of the head, irregular, not tender; has no explanation to offer for its presence, in fact, was not aware of it being there.

On the recommendation of the officer making the above report, the patient was referred to a consultant for mechano-therapy and hydrotherapy. The consultant reported:

I find no sign of any organic disease, muscular and skeletal systems being apparently normal. He has, however, a well marked "traumatic neurosis" similar in every respect to the so-called "railroad spine." In other words, the condition is purely functional, but as such is none the less serious so far as ultimate recovery is concerned. The effect of treatment in this man's case would be problematical, so much so that I could hardly recommend its being instituted. The only thing that might be tried would be of a suggestive nature and associated with moderately severe electrical applications. In the above findings I have had the assistance and corroboration of Dr. ——, neurologist.

In May, 1919, Doctor N., who had handled many cases in New York City for the Commission, having returned to Montreal, the case was referred to him. He reported:

After his return home from the hospital the patient gradually regained the use of his legs, and the condition of his mind slowly improved. He has never, however, regained his normal mentality, and today presents the picture of a man not far removed from insanity. His scalp shows scars dating from his fall. His gait is weak and uncertain, and as he walks he supports himself with his hands on any nearby chair or wall. He has to sit down to rest frequently. His arms, legs, and feet are good.

Fig. 2.—The picture at the left is an X-ray photograph of leg taken three months after the injury occurred, showing unsatisfactory position of fragments, due in a large measure to inexpert or careless treatment. At the right is another photograph of the same leg, giving an antero-posterior view of the fragments.

The pain in his back, moderate in severity, is present most of the time, and is probably due to sprain. There is some anteroposterior irregularity at the dorsolumbar junction, but the vertebral movements are very fair for a man of his age. His memory is poor; his response to questions hesitating. He will, in my opinion, never be able to work

May 21, 1919

again at anything. I do not think that his mental condition is capable of being improved. Something may possibly be done to relieve the pain in his back, but a more accurate diagnosis will need to be made with the help of x-ray. His disability is, of course, total and in all probability permanent, depending practically entirely on his mental condition rather than on his back. Disability is irreparable cerebral injury.

On June 23, Dr. N., advised the Commission that the patient had appeared at his office a few days pre-

viously to learn whether anything could be done for his backache, that he had x-rayed him and found that at the time of the accident the patient had sustained a compression fracture of the eleventh and twelfth dorsal vertebrae, and that this was the cause of the persistent backache. A back brace was secured and gave the patient much relief.

The method adopted by the Commission to furnish proper medical and surgical service has been the designation in connection with each hospital of one or more competent, well trained surgeons of established reputation, and the requirement that every compensation case going to the hospital shall be placed under the immediate care of one of the designated surgeons. With this arrangement the hospital renders its bill for hospital care. The surgeon submits his bill for professional attention. This insures to the injured employee the personal and interested service of a competent physician, and gives to him the same close atten-

tion he would receive as a private patient of a reputable, competent practitioner. If the services of other specialists or consultants are required, the attending surgeon secures such services, submitting bills therefor.

When the Commission first began the designa-

Fig. 3.—X-ray photograph of femur taken six weeks after injury occurred, showing unsatisfactory position of fragments due to expert or careless treatment.

tion of physicians and hospitals as required by the law, the question arose as to what qualifications, if any, it should require before designating a physician. The idea existed at first that the Commission could not restrict itself to the designation of highly qualified and experienced men, surgeons particularly, most of the injury cases being surgical in nature, as it was supposed the charges for expert service would be exorbitant, or at least greater than the Commission would be justified in paying. It soon became apparent, however, that the Commission could not afford the services of any but the most competent men available in the locality. The handling of injury cases by physicians of insufficient training and experience resulted frequently in the making of permanent cripples, particularly in bone and joint injury cases, which might have been prevented by the services of competent orthopedic surgeons, and showed the fallacy and extravagance of securing the services of any but well trained and experienced surgeons.

After arriving at this conclusion and acting upon it, the Commission was happy and, in a measure surprised, to find that the bills presented by the well trained and experienced surgeons were in general no greater than the bills presented for treatment of similar cases by men of inadequate and insufficient training. In fact, the charges made by the most competent men have been on the whole the most reasonable, particularly so when the much better service rendered is considered. A permanent cripple is a charge against the Commission as long as he lives. Every employee restored to work, every cripple prevented, is an economy.

Fee Schedule Impracticable

The question arose as to whether the Commission should adopt a schedule of rates or charges that it would pay for medical and surgical service; in fact, the matter obtruded itself upon the attention of the Commission for everyone seemed to expect, as a matter of course, that a fee schedule would be adopted. However, one has not been adopted. It seemed that at best a fee schedule was an inaccurate and cumbersome thing by which to work, as probably the same service would seldom be rendered in any two cases, and it was service the Commission wanted, service that would put men back to work physically sound and that would prevent unnecessary cripples.

The plan adopted was to use as great care as possible in designating, under the provisions of the Act, only men with adequate training and considerable experience in surgery, of mature age, and of established reputation in their respective communities; and then to explain to those appointed that the purpose of the Commission was to secure service; that in bone or joint injuries the Commission expected x-ray examination and control; that where there appeared to be any reason therefor, neurologists, pathologists, or other specialists should be called in consultation; that the purpose of the Commission was to make the best possible restoration of the injured person; and that as regards charges the Commission merely expected that the charges would be reasonable for the service rendered.

The Commission has found that this arrangement was acceptable to and welcomed by the class of men they selected,—a class of men whose services it would have been impossible to obtain under the limitations of a fee schedule,—and this notwithstanding the fact that the fees actually charged have been within the limits of any reasonable fee schedule which might have been adopted. Should the Commission find one of its designated surgeons giving inadequate service or

making unreasonable charges, it has recourse to cancellation of his designation; but there have been exceedingly few instances in which this has been called for.

Hospitals Chosen by Surgeons

The hospitals are now usually designated on the recommendation of the designated surgeons. When a surgeon is designated, he is asked to indicate the hospital he would like to use for the injury cases requiring hospital treatment. A hospital schedule is then sent to the hospital and, when returned, the hospital is designated, if satisfactory.

An injured employee goes or is sent to the designated surgeon. If he is a hospital case, the surgeon sends him to the hospital. In serious injuries, the injured employee is usually taken direct to the hospital and the designated physician who is to take care of the case is notified by messenger or telephone.

The Commission has, in a measure, followed the policy that beneficiaries should be placed in the general ward of the hospital unless, in the opinion of the surgeon, the case is such that a private room is necessary. When necessary, special nurses are allowed. In fact, any service is allowed which is actually needed by the patient.

The Commission has found that its policy with regard to ward service has not been possible of uniform application. It has been found that in many hospitals the service given in the general ward is not the kind which the Commission would be justified in imposing upon its beneficiaries. Under such conditions the Commission allows and desires the use of private wards or, if these are not available, private rooms. The minimum of service which it feels justified in furnishing under the law is one in which there are clean beds in a clean ward, with adequate nursing and orderly attention, and suitable diet. When a beneficiary for his own convenience desires a private room, when ward service is available, he may secure a private room by paying the difference between the ward rate and the rate for the room.

The experience of the Commission may be summarized briefly as showing:

(1) In government hospitals and dispensaries the service rendered varies with the training and personality of the members of the staff's.

(2) In non-government hospitals good medical and surgical service is usually not obtained unless the cases are put in charge of selected physicians or surgeons paid by the Commission.

(3) Paying the "doctor's" bills for an injured employee is not synonymous with furnishing reasonable medical and surgical service.

(4) Reasonable and adequate medical and surgical service can be obtained only from conscientious physicians and surgeons with good training and experience.

ILLINOIS REPORT ON HEALTH INSURANCE

The Illinois Health Insurance Commission, a legislative body appointed in 1917 to study and report on the problem of sickness, the incidence of sickness, and health insurance, estimates that probably 20 per cent of all wage earners will suffer a disabling illness of more than seven days in a year, or as the result of accidents arising from nonindustrial causes. Sickness was found to be the cause or an accompanying condition in from one third to one-half of the cases in which charitable aid was sought. In about 20 or 25 per cent of cases in which sickness is a cause or condition of dependency, tuberculosis, and other chronic conditions were found to exist. The majority report states that, after analysis of the results achieved by compulsory health insurance systems abroad, it is believed that compulsory health insurance is not an important factor in the prevention of disease or in the preservation of public health. A minority report was presented by Dr. Alice Hamilton and Dr. John E. Ransom in which it is contended that health insurance will bring about a more equitable distribution of the costs of sickness.

FACTORY INSPECTOR OF GREAT BRITAIN LECTURES AT HARVARD

Harvard University announces that Dr. Thomas M. Legge, chief medical inspector of factories in Great Britain, has been invited to give a course of Lowell lectures and the Cutter lectures in preventive medicine for the coming year. These lectures will be given under the auspices of the School of Public Health of Harvard University and the Massachusetts Institute of Technology, and the division of Industrial Hygiene.

Dr. Legge will lecture in Boston on November 18 and ensuing dates upon the following subjects: "Twenty Years' Experience of the Notification of Industrial Disease," "Twelve Years' Experience of Workmen's Compensation Act and Industrial Diseases," "Medical Supervision in Factories," "Industrial Poisons and Their Prevention," "Anthrax," "Fumes and Gases," "Industrial Fatigue," "Industry as a Subject for Art," "Manufacture Under the Mediaeval Trade Guilds." The completed schedule of lectures will be issued on October 20.

"All voluntary and public effort to promote safety, sanitation, and hygiene, to prevent accident, to destroy infection and contagion, whether it be related to proper water supply, to sewage disposal, to pure food to proper housing, ventilation, lighting, and recreation, to medical supervision, or to any other form of social control in the interest of safety and health, may very properly be viewed in the light of service rendered industry by the community for which the community has a right to expect service of like kind on the part of industry. Instead of proper standards of working conditions in industry being viewed as a concession by capital to labor, they should be regarded as at least the necessary complement of those measures of public safety and public health which are primarily for the benefit of the community as a whole, and which are also of direct and immediate benefit to capital and management.—W. I. Mackenzie King, C.M.G., LL.B., Ph.D.,—"Industry and Humanity."

USES OF MOTION PICTURES IN INDUSTRIAL DISEASES

BY LESLIE WILLIS SPRAGUE, DIRECTOR, INDUSTRIAL SERVICE SECTION, COMMUNITY MOTION PICTURE BUREAU, NEW YORK

THIE motion picture, under wise and careful management, readily lends itself as an aid to the progressive industrial physician. It is capable both of general utility and special services.

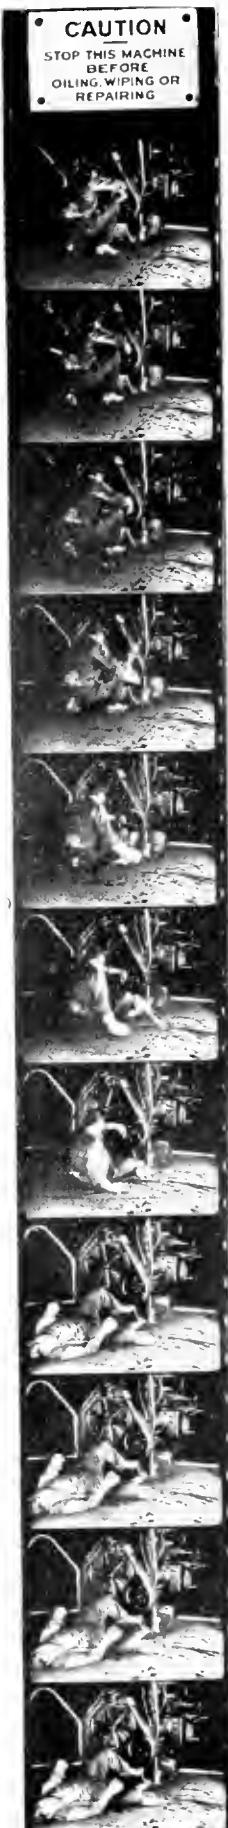

The company physician, responsible for the families of employees as well as employees themselves, is particularly in need of effective educational agencies. He cannot hope personally to disseminate the knowledge necessary to enlighten the public and the private opinion of his community to a degree necessary to safeguard the families under his care from contagion and epidemic. Nor can the usual nursing staff at the disposal of the industrial physician hope more than to follow in the wake of disease; they cannot anticipate and meet in advance the diseases which ravish the homes of the workers. But motion pictures now available, or easily to be produced, are capable of carrying the doctor's wisdom and the nurses' sure methods of precaution into every home of the industrial community.

Three Urgent Necessities

Three things are imperative. To cut down the inroads which diseases peculiar to particular industries make in the ranks of the workers, the industrial management must discover and be quick to install all necessary devices, enforce needful regulations, and comply with the laws of health as science discovers them. The industrial physician must, with the aid of health devices and wise care, look after whatever percentage of the employees the best regulations fail to protect; and the workers must be brought to a willing and effective cooperation in making the health rules and the physician's care as potent as possible, both in the cure and prevention of industrial diseases. In all three of these necessary interests motion pictures should have an effective part.

The Industrial Manager

Managers need education in the economics of industrial health. The conscience of many industrial managers, responsible for the private welfare of employees and the general welfare of the community, still remains in need of quickening. Not all who are responsible for the conduct of industry are ready to hear and adopt the recommendations of their industrial

*The third of a series of three illustrated articles by Leslie Willis Sprague describing the use of the motion picture in promoting interest in public health: (1) "Motion Pictures in Public Health"; (2) "Motion Pictures in Industrial Medicine"; (3) "Motion Pictures and Industrial Diseases." The first of the series appeared in the August issue.

In a badly ventilated and dusty pottery plant the doctor finds the workers easy prey to tuberculosis. The deleterious effects of dust may usually be prevented by the use of ducts, hoods, and fans.

physicians, nor, indeed, to employ health experts to care for their employees. A field is here open for some national agency, at least for some general association representing each of the leading industries, to provide (producing if necessary) films which will bring home to the manager of particular industries the pertinent needs which they must specifically meet in order to promote their own, their employees', and the public welfare.

The breathing of emery dust, for example, lessens the usefulness and shortens the lives of many grinders. It is questionable how large a percentage of emery wheels in the United States are equipped with devices for bearing away the lung-destroying dust. All employers who are not awake to the necessity of improving upon any such device until its work shall be 100 per cent efficient, are in need of a motion picture program to bring graphically to their attention not only the need, but the surest method of its fulfilment.

Pictures for Industrial Physicians

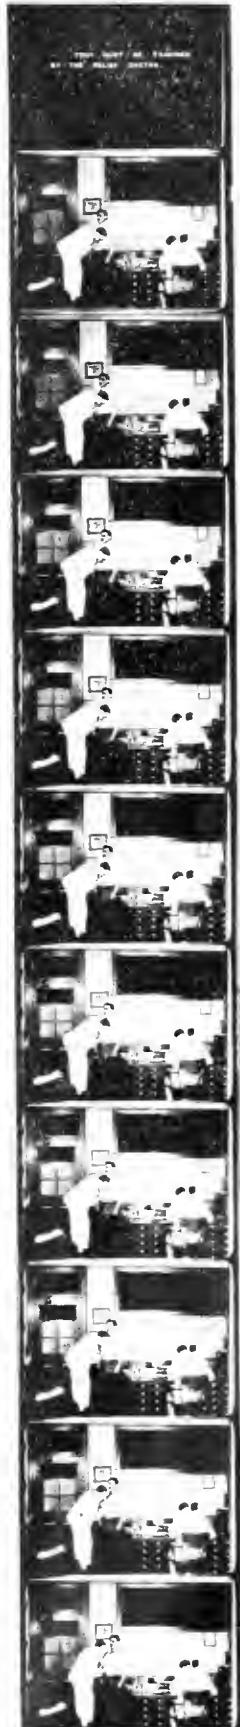

Many earnest industrial physicians who were obliged to cope a year ago with influenza found various means of at least checking the dread contagious disease. The result of such successful experience should be put before all employers in a way to ensure the immediate installation of the best program of defense, should another epidemic more devastating than war make itself known in our midst. As yet no adequate presentation of this subject has been done in motion pictures. Here is a responsibility for the Rockefeller Institute, the United States Chamber of Commerce, or possibly for the Federal Government.

Physicians in charge of industrial health, and nurses who assist them, are another audience for motion pictures which deal with the means of protecting the lives of the workers. Actually to see upon the screen methods introduced and results accomplished by successful experts in dealing with epidemics would be more informative than convention reports or anything but the actual visitation of the fortunate plant while the experiment was being tried. Motion pictures dealing with the prevention of typhoid, infantile paralysis, smallpox, and tuberculosis have a proper place in the meetings of medical associations, especially meetings particularly concerned with industrial health.

Health Education for the Workers

The largest and most needy group who should see motion pictures dealing with industrial diseases, their prevention and cure, is naturally the workers, whose attitude toward all health regulations and contagion-prevention is the most important fact to be reckoned with and is the frequent cause of partial or total failure of the wisest plans.

Doctors are not always trusted by the laity, and industrial physicians, partly owing to the paternal-

The presence of a plant physician conveniently accessible to the men encourages early consultation in disease or sickness.

istic nature of their office, are frequently far from the confidence of those whom they seek to serve. Their councils are often questioned, their devices scorned, and their orders disregarded. It is here that the impersonal motion picture comes to the aid of the industrial physician.

To put upon the screen pictures showing health measures adopted in other plants, perhaps in other countries, and to present the successes of such measures in safeguarding the lives of other workers, would be to create a demand on the part of the workers for such protection. Wise is the industrial physician or employment manager who, heeding Emerson's dictum regarding education, "never answer a child's question until he asks it," proceeds to the creation of a demand on the part of the workers for any new departure before attempting to supply the thing which he knows to be beneficial. Motion pictures not only help to create a reasoned demand for health devices, but, wisely used, they contribute to the group opinion which is necessary to the successful working of every regulation and device introduced in an industry.

Pictures to Be Produced

There is serious need of the cooperation of leaders in industrial health with the producers of motion pictures in order that a more adequate treatment may be given to many important and greatly neglected subjects. There is still need of scientific cooperation in the production of motion pictures dealing with such subjects as a reasonable diet, the necessity of adequate sleep, fresh air in sleeping rooms for other reasons than tuberculosis prevention, infection, eye strain, various occupational diseases, not to mention other subjects. To be largely useful, these subjects should be produced not for advertising, but only for scientific and public welfare purposes.

Available Material

There is no need, however, to wait for new production in order to use motion pictures effectively in stamping out epidemics and in promoting a right attitude of mind on the part of workers toward programs instituted by health physicians. Enough film material is now at hand to ensure the success of motion pictures in meeting the problems of the industrial health expert.

When employers of labor realize, as they are realizing increasingly, the importance of motion pictures in the industrial plant as a means of stabilizing labor conditions, cutting down the turnover, and promoting Americanization, as well as wholesome and needed recreation, and when, realizing this, they install motion pictures prop-

erly programmed for producing the desired results, then the health officers in industry will not be slow to cooperate in planning motion picture programs to further the interests they have in hand and at heart.

PENNSYLVANIA COMMISSION SUBMITS HEALTH INSURANCE REPORT

Large numbers of the working population of the state of Pennsylvania endure periods of illness without proper medical attendance, and the hospitals of the state provide an average number of beds only a little more than one-half the recognized minimum of five beds per thousand of population.

Thus the facts are presented by the Health Insurance Commission of Pennsylvania in the report submitted early in September pursuant to instructions voted by the legislature in 1917, when the Commission was formed.

There are constantly ill in the state of Pennsylvania more than 385,000 employees, of whom approximately 140,000 are suffering from severe illness and 245,000 from less serious illness.

The commission set out to do its work with an appropriation of only \$5,000 available. Due to the enforced limitation imposed by the sum voted by the legislature, the commission made no survey or investigation other than a study of the data which others have compiled. The figures of the draft are taken as an evidence of the extent of illness and disability, and the registration of deaths, births, and communicable diseases furnishes convincing testimony of the unnecessary or preventable sickness that exists.

Pennsylvania had the highest percentage of any state in the number of men rejected for military service. The proportion of those rejected for physical defects was 46.67 per cent. The average for the entire country was much lower—29.11 per cent.

From the data gathered by other agencies the commission concludes that the average loss of working time for all employees exceeds six days per year. The death rates in Pennsylvania are higher than the average also, and the infant death rate in Philadelphia, in 1917, was higher than that of New York City, Brooklyn, Boston, or Chicago. The state as a whole had an infant death rate in 1916 of 114 per thousand as compared with 101 per thousand in the registration area.

The loss to employees in wages missed is estimated at \$33,000,000 per year, with a corresponding loss to employers in curtailed production and labor turnover.

The lowest paid wage groups suffer the most and have the least opportunity to procure adequate medical care. Approximately one-fourth of those disabled by sickness actually never receive medical care. Insurance protection against sickness either by employees' benefit organizations, fraternal societies, or other forms of benefit organizations, extends to only 30 per cent of the workers.

The commission places the responsibility for sickness equally upon each of three groups—the industry, the community, and the individual. Some form of health program is advised which will guarantee medical service to employees and their families. No definite plan of health insurance is proposed, but the commission recommends that a new appropriation be authorized and a commission appointed to continue the investigation and to study the existing plans of health insurance in this country and abroad with a view to formulating definite measures.

HEALTH SERVICE THROUGH EMPLOYEES' MUTUAL BENEFIT ASSOCIATION

BY BERT HALL, SECRETARY, E.M.B.A., THE MILWAUKEE ELECTRIC RAILWAY AND LIGHT COMPANY, MILWAUKEE, WIS.

THOSE who rely on Government statistics to prove a given point, find on investigation that they have chosen a weak reed on which to lean, as the figures of one Governmental Department may vary a few millions from the figures accumulated by another department on the same subject. This is particularly true with statistics in regard to health and sickness. Weak as Government statistics are on practically all subjects, they are particularly weak in regard to the subject under discussion.

However, if one takes the United States census figures and compares them with the figures accumulated by certain insurance organizations, labor organizations and other agencies, one is forced to the conclusion that the average wage earner in the United States loses approximately nine days per year on account of sickness. Such statistics as we have indicate that there are approximately thirty-five million wage earners in America and if each one of these loses nine days per year the economic loss is something enormous. This loss would amount to 315,000,000 work days and at wages which now probably average not far from \$3.50 per day gives the grand total of \$1,102,500,000.

Reduce the Economic Loss

Any effort on the part of the medical profession or any other organized effort which would reduce this loss even 10 per cent would result in a saving of vast suffering, and would permit wage earners to increase their yearly earnings by more than \$100,000,000.

We propose to show in this article that it is possible to reduce this loss by fully 33½ per cent, entailing a money benefit to the wage earners of America of at least \$30,000,000 per year.

If we are to believe the arguments advanced by the advocates of compulsory health insurance, legislation compelling insurance is needed in most

In a group of more than four thousand employees residing in a territory that extends over a large portion of southeastern Wisconsin, the loss of time from sickness has been reduced approximately 50 per cent through the activities of an employees' mutual benefit association that regards the conservation of health and the prevention of sickness as a duty of greater importance than merely the payment of sick benefits. For the purpose of giving prompt medical attention to members and their families the territory is divided into districts and an association physician assigned to each district. Prompt medical attendance lessens the amount of sick benefits that must be expended.

of the states to bring about this very much desired result. To the writer this plan of attempting to improve health conditions through compulsory health insurance laws is un-American and would not produce the results claimed for it. The best statistics obtainable from England and Germany, where such laws have been enacted, and especially from Germany where it has been tried out for nearly forty years, in-

dicate that the time lost on account of illness has steadily increased and the duration of each case of sickness has steadily increased. This would indicate either that the doctors who go upon the "Panels," as they are called, for ministering to insured persons are not the best physicians, or it may indicate that there is a vast amount of malingering; whichever one of these investigations proves to be correct, they are equally bad.

Sick Benefits vs. Health Promotion

The author believes that there is a better method of reducing the time lost than through a compulsory health insurance law, with all of the cumbersome political machinery which must be put in motion before any results are obtainable under such a system.

When one speaks of a mutual benefit association, one is very apt to think of an association organized principally and solely for the purpose of administering a fund from which benefits shall be paid to men suffering from illness. An investigation of mutual benefit associations would probably show that 99 per cent are content with this one function and that the directors of these organizations have never seen the wonderful opportunities placed in their hands for improving health conditions and reducing the time lost on account of illness.

The object in what follows is to give as clearly as possible some idea of a mutual benefit association which is organized and working along these

health conservation lines, and which has succeeded in reducing the time lost on account of sickness among its members approximately 50 per cent.

As this organization has a membership of more than four thousand, and extends over a large portion of the southeastern part of the state of Wisconsin, the group under consideration is large enough to establish some fairly definite conclusions.

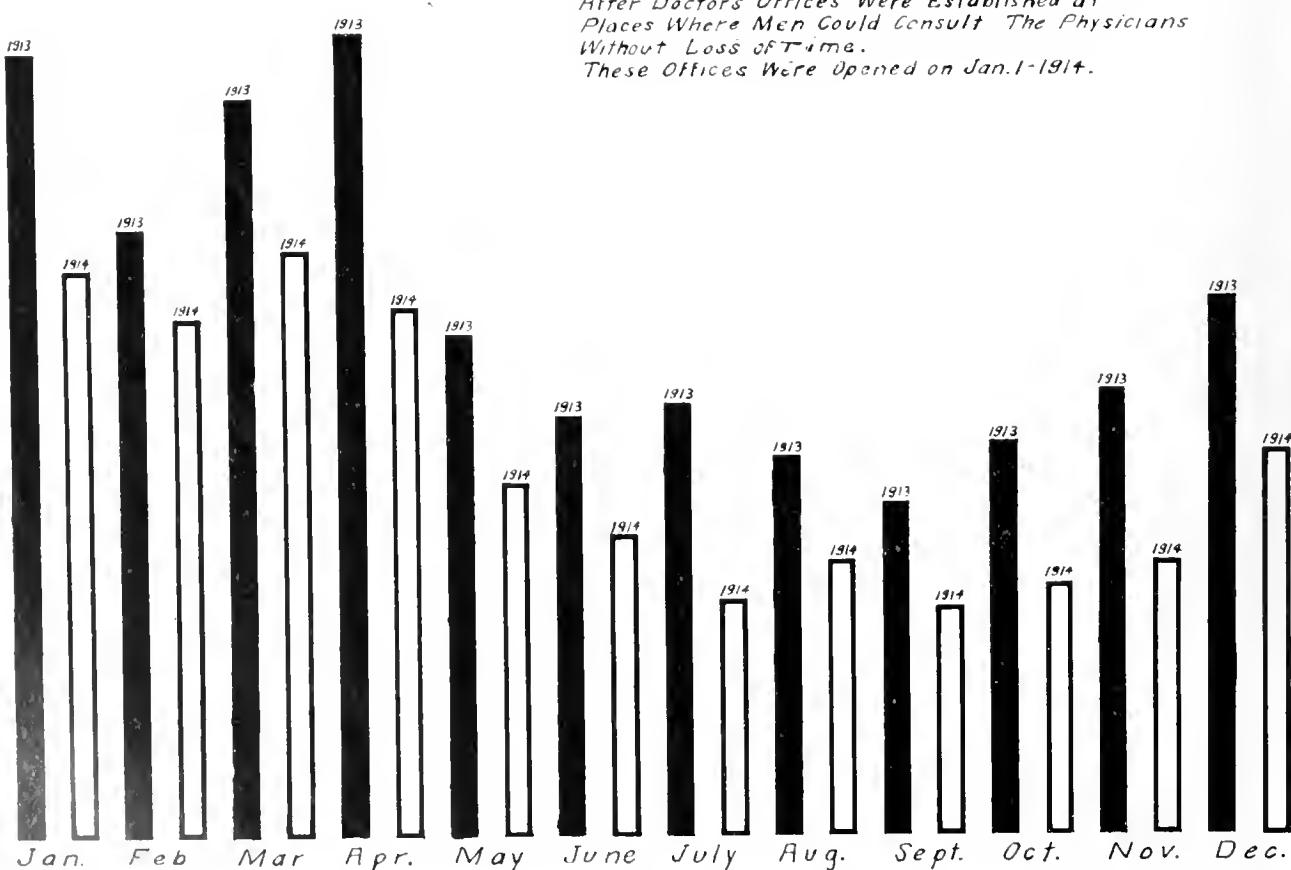

Association of Employees Formed

The Employees' Mutual Benefit Association is made up of approximately four thousand members, employees of the Milwaukee Electric Railway & Light Company, the Wisconsin Gas & Electric Company, the Wells Power Company, and a number of other smaller concerns engaged in furnishing street-car service and electric and gas service in the cities of Milwaukee, Kenosha, Racine, Burlington, Watertown, Oconomowoc, Waukesha, and a large number of other smaller towns and villages in the southeastern part of the state. Within the membership there are approximately 170 different trades, callings, and professions, covering practically the entire industrial workers' field.

On March 1, 1912, the employees of these com-

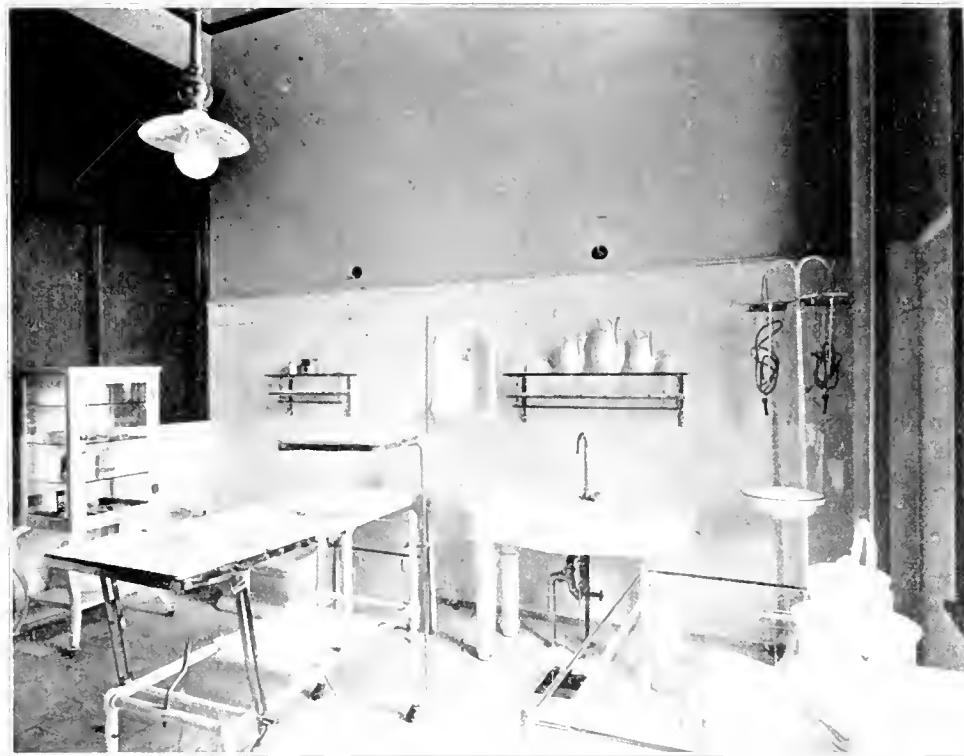

panies organized a Mutual Benefit Association, acting under the inspiration and guidance of the management of the companies. The business affairs of the Association are conducted by a Board of Directors, jointly elected by the employees and appointed by the company. The employee directors number thirteen and those appointed by the company number eleven, giving the employees a working majority on the Board of Directors. At the organization meeting, Dr. Charles H. Lemon, one of the most eminent surgeons of Wisconsin, was appointed as medical director of the Association, and the wonderful results achieved during the past eight years are largely due to the skill with which he has administered the medical affairs of the Association.

For the purpose of giving prompt medical attention the territory covered by the companies is divided into districts and a physician of the Association is in charge of each district having sufficient members to warrant the appointment of a physician. Members residing in districts where there are not enough members to warrant the appointment of a regular Association physician, may call their family physician and the physician's bills are paid out of the funds of the Association. The regular district physicians of

the Association are paid a fixed fee for taking care of members of the Association; in the case of married members, there is an additional fee for taking care of the wife, and still another additional fee is allowed for taking care of the children if there are children in the family.

physician before the physicians would give them attention. This was much more satisfactory, but a careful survey of the operation for a period of twelve months showed that the average man would not call the Association physician until the illness with which he was suffering had run for

Operating room at the office of the medical director where minor operations are cared for. All major operations and many of the more serious minor operations are taken to a hospital.

Members of the Association are taken care of both medically and surgically, medical and surgical attention comprising all ordinary medical and surgical care, including obstetrics, but not including the services of specialists.

Extent of Service Rendered

From the very beginning the object of this Association has been to conserve the health of its members by giving prompt medical attention. At first an attempt was made to send the doctors to the home of every employee who reported himself away from work on account of sickness. This did not prove satisfactory either to the doctors or to the men, as a number of the men belong to lodges which furnish medical service and the Association physician would arrive at a man's house only to find that the doctor from the lodge had already called, or discover that the man had taken a dose of physic and was staying home in consequence and did not need the service of a physician.

The rule was then established that men who reported themselves as being sick would be required to call for the services of the Association

several days. It was thereupon decided that an improvement could be made by opening doctors' offices at all places where men were employed, so that men could be sent to the doctors' office immediately, and without loss of time, as soon as the first symptoms of illness appeared.

Prompt Care Saves Time Loss

It became at once the duty of foremen and superintendents to send their men to the doctor's office upon the first appearance of illness. At the end of twelve months of operation under this plan remarkable results had been achieved. It was found by comparing the figures of 1913 with the figures of 1914 that a reduction of 35.1 per cent in the time lost on account of sickness had taken place. In other words, the average time lost per man had been reduced from a fraction over 8 days per year to a fraction over 5 days per year. As time has gone on the system has been improved and men have learned the importance of calling a doctor on the first appearance of symptoms of illness, this has been still further reduced until the average days lost per man per year is 4.24. It thus appears that this system of prompt atten-

tion has resulted in the whole organization in a saving of approximately 20,000 days per year that were formerly lost on account of illness.

It is a fixed rule of employment that every man who is confined to his home by illness must

report to his superior the fact of his illness. When he does report his illness, the question is immediately asked, "Do you wish to have the Association physician sent to you?" If the reply is in the affirmative, and it usually is, the physician is at once notified to call at the man's residence. This plan insures prompt attention to those who are confined to the house by illness.

Conservation of Health Saves Funds

The conservation of the health of its members has resulted in a conservation of the funds of the Association. By reducing the time lost on account of sickness, there was a corresponding reduction in sick benefit; the surplus of the Association grew rapidly and now amounts to a substantial figure from the income of which addi-

Patients waiting to see Association physician.

tional benefits have been extended to the members of the Association.

The members of the Association, at present, have the following benefits: \$1.00 per day sick benefits for the first one hundred days, \$0.50 per day for the second one hundred days of illness, \$150 being the maximum that any member can receive within any twelve months. There is a \$300 death benefit. The Association cares for the wives of all married men and for their children under eighteen years of age for all ordinary medical attention and all surgery excepting special surgery. The Association also provides three nurses to give attention to those who are seriously ill and in need of the services of a nurse.

It has been found from our experience that this care of the wives and children of employees of the company and members of the Association has a beneficial influence on the health of the men themselves, due, no doubt, to the fact that the wives, being kept in better health, are better able

The Employees' Mutual Benefit Association Fair, 1918. Vegetables and fruits grown and exhibited by members.

to attend to the household duties and keep the home in such excellent condition that there is a direct result in the improved health of their husbands. The peace of mind that comes to the laboring man who knows that, in case of an accident or serious sickness, his loved ones will be promptly and efficiently cared for certainly has a tendency to improve the mental condition of the worker and indirectly to affect his general health beneficially.

Loans and Pensions Provided

This Association has proved by its experience of eight years that it pays to assist men in all ways which will tend to reduce to a minimum the nervous and mental frictions of life. It has a system by which men are relieved from financial worries by loans of small amounts which will tide

them over a financial emergency, and has very effectively prevented all garnishment actions being brought against its members. This latter result has been effected by securing the cooperation of collection agencies, law firms and houses selling goods on the installment plan.

Another important feature of the Association is its pension system, which provides a minimum pension of \$240 per year for men who have been in the service of the employing company for a period of fifteen years and who have reached the

perform many other neighborly acts which make them very useful in the organization, taking away from the patient every worry that can be removed by their cooperation, and making the conditions ideal for the recovery of the patient.

The Women's Auxiliary has taken a very active part in all of the social affairs such as dances, entertainments, card parties, and similar social affairs held during the winter season in the audi-

Office of one of the association physicians at one of the car stations.

torium of the Public Service Building, the company's office building, and at the club rooms at the various car stations.

Another feature of the work which undoubtedly has a bearing upon the general health of its members is the general welfare work performed by the secretary of the Association. Members of the Association are at liberty to lay before the secretary any of the serious problems which confront them, and which tend to make them nervous or worried and detract from their general physical welfare. That the members are taking advantage of this opportunity and that it is an element in the general health conservation plans of the Association, is evidenced by the fact that approximately three hundred individuals call on the secretary during each month of the year. During the year 1918 there were 3,511 calls made at the secretary's office and the secretary made a total of 3,621 calls outside of his office in helping members to straighten out their problems.

The employing company owns several large tracts of land in the city and suburbs, and arrangements have been made with the company through the Association for each member who wishes to use a small tract of this land for garden

purposes. A large number of its members have received the healthful recreation which comes from the cultivation of a garden and have helped to reduce the cost of living by the raising of vegetables.

Each year, at the close of the gardening season, a fair is held in the auditorium of the Public Service Building, where the fruits and vegetables raised are displayed, and where those who are raising chickens, Belgian hares, cavies, or other live stock are at liberty to exhibit same. Suitable prizes are offered.

After pointing out many benefits which this Association gives to its members, one is tempted to explain also how this work has reacted upon the members of the Association in establishing a

closer and a more mutual relationship between employer and employee but, as Kipling says, "That is another story," and has no place in an article of this kind. The work being done by the Association is work that could be taken up by any corporation with a management broad enough in its views to see how important this work is. It throws around the workers of this organization

every protection that is possible for human ingenuity to devise in the way of health protection, and has established a relationship between the employing company and its men that cannot be duplicated in any similar organization in America. It is constantly proving its worth to the workers, to the owners, and to the general public whom it serves.

CARBON MONOXID POISONING—THE TOXICOLOGY, SYMPTOMATOLOGY, AND TREATMENT

BY R. P. ALBAUGH, M.D., CLEVELAND, OHIO, FORMERLY DIRECTOR DIVISION OF INDUSTRIAL HYGIENE, STATE DEPARTMENT OF HEALTH

CARBON monoxid is one of the most frequent causes of industrial poisoning. It is extremely toxic, as little as 0.5 part per 1,000 in the atmosphere breathed having a poisonous effect, while 2 to 3 parts per 1,000 can be dangerous to life. It occurs chiefly as the result of incomplete combustion of carbonaceous material, and poisonous effects have been reported from a great variety of industries.

Haldane was responsible for the widely accepted theory that the gas was toxic by virtue of its power to unite itself with the hemoglobin, replacing the oxygen and forming a stable compound which he termed carboxyhemoglobin. This theory has apparently been disproved by Henderson who, as a result of experiments, concluded that the gas is physiologically harmless except in its affinity for hemoglobin, and that it does not form a permanent compound with hemoglobin, but is rapidly separated from it in the presence of pure air or oxygen.

Symptoms.—There is apparently some controversy also as regards the occurrence of chronic carbon monoxid poisoning. Hamilton states that poisoning is chiefly chronic, the acute type being comparatively rare. Chronic poisoning is at least quite prevalent.

In acute cases, if a large quantity of the gas is inhaled, the affected person immediately falls and succumbs after breathing a few times. In less acute cases there is dizziness, headache, "weakness of the knees," giddiness, palpitation, and shortness of breath, followed by drowsiness and unconsciousness. The lips are usually blue or bright red in color, and there may be red blotches on the skin over the entire body. If such cases are withdrawn from the poisonous atmosphere immediately, they may recover. Not infrequently, death occurs considerable time later from the symptoms described.

Chronic carbon monoxid poisoning sets in usually with symptoms similar to those in the mildly acute cases. Such cases usually become irritable and neurasthenic and complain of headache, anorexia, loss of weight, backache, vertigo and gastro-intestinal disorders. Apfelbach states that there is usually a polycythemia, the red cell count varying from 5 to 10 millions.

Complications and Sequelae.—The after effects of poisoning are of importance because of their severity and the frequency with which they occur. Broncho-pneumonia, skin affections, and nervous and mental disturbances are those frequently encountered. Many cases of mental disturbance resulting from carbon monoxid poisoning, occurring under rather peculiar circumstances, have been reported. Some of these cases apparently recover, while others have been under treatment for years with no apparent improvement.

Treatment and Prevention.—All cases of carbon monoxid poisoning should have the benefit of fresh air at once. Oxygen inhalation for a brief period is of value; otherwise, the treatment is symptomatic.

Prevention depends upon the elimination, whenever possible, of sources of the gas, and the protection of those necessarily exposed to the gas by helmets or other means. When there is doubt regarding contamination of the air, analysis of the air should be resorted to. When it is considered that 1 part of gas per 2,000 parts of air is poisonous, the necessity of altogether preventing even slight contamination of the air is readily apparent.

Keep On!

Keep on looking for the bright blue skies,
Keep on hoping that the sun will rise,
Keep on smiling though the whole world sighs,
And you'll get there in the morning.

—“*The Bambino.*”

INDUSTRIAL PHYSICIANS AND SURGEONS HOLD CONFERENCE

The Ninth Conference of Industrial Physicians and Surgeons with the Division of Industrial Hygiene and Engineering of the Department of Labor and Industry of Pennsylvania, was held at Harrisburg, Monday, September 22, 1919. The meeting was quite largely attended by industrial physicians and by members of the Pennsylvania Medical Society, who convened on the following day for the annual meeting of the Society. The meeting was presided over by Francis D. Patterson, M.D., chief of the Division of Industrial Hygiene and Engineering, of Pennsylvania, and the address of welcome was extended by the new director of the Department of Labor and Industry of Pennsylvania, the Honorable Clifford B. Connelley, who pointed out the growing importance of industrial medicine and of the new developments in workmen's compensation and rehabilitation in the state of Pennsylvania.

Frederick L. Van Sickle, M.D., president of the Medical Society of Pennsylvania, addressed the convention on "The Medical Profession, and the New Workmen's Compensation Act of Pennsylvania." Doctor Van Sickle was chairman of the legislative committee which secured the improvements in the Pennsylvania law. He pointed out that medical benefits had been extended to a maximum of one hundred dollars and the length of time to thirty days. He warned the members, however, that Pennsylvania is still short of the standards set in other states for workmen's compensation acts.

C. A. Emerson, Jr., chief engineer of the Department of Health, discussed the sanitary disposal of sewage and trade wastes, and the drinking water supply in factories; he brought to the attention of the meeting the serious dangers that are found in plants from the careless drinking of unfiltered water.

"The Application of War Surgery to Industrial Practice" was well presented by Drury Hinton,¹ M.D., medical supervisor of the Harrison Works, the E. I. Dupont De Nemours Company, formerly a captain in the Medical Corps of the United States Army.

The afternoon session was devoted to the subject of health insurance. John B. Andrews, secretary of the American Association for Labor Legislation, presented the subject "State Medicine or Health Insurance—Which Would Be Best for the Medical Profession—for the General Public?" Doctor Andrews detailed briefly the history of the movement for health insurance in this country, and discussed the advantages of health insurance to the physician in preference to the indefinite plan of state medicine suggested by opponents of health insurance. The speaker had just returned from several weeks' investigation in England and brought many first-hand impressions of medical service under the British Health Insurance Act.

George E. Tucker, M.D., of the Aetna Life Insurance Company, Hartford, Conn., discussed the subject "Have the Medical Profession Adequately Met Their Responsibilities?" After outlining the contributions which physicians have made to social welfare, Doctor Tucker pointed out the necessity of organization to protect the rights of the physician.

"The Cost of an Adequate Medical Service Under Health Insurance," was discussed by John A. Lapp, managing editor of MODERN MEDICINE. The speaker gave detailed statistics of the probable amount of medical service

which would need to be paid for under a health insurance plan. Allowing liberally in most cases for the physician's compensation, he estimated that the medical service for a million men and their dependents would approximate from fifteen to seventeen dollars *per capita*, or from \$15,000,000 to \$17,000,000 for a million men.

A general discussion followed in which it was strongly urged that the Medical Society keep an open mind in the study of the subject in order that adequate provision might be assured for the medical care of the sick under any plan adopted.

CHLORINATION AS A CHECK TO WATER-BORNE TYPHOID

In a paper describing the relation of the chemical industry of Niagara Falls to waterworks, John A. Kienle, of the Electro Bleaching Gas Company, New York City, in an address given at the 1919 convention of the American Water Works Association, gave a summary of the chlorination of water from the first use of hypochlorite of lime at the Union Stock Yards at Chicago, in 1907, to the use of liquid chlorine by approximately 2,500 water works plants at the end of 1918. In 1911, four years after the first use of hypochlorite of lime, approximately 500 water plants were equipped with hypochlorite installations. In 1912 the Niagara Falls, N. Y., plant was equipped for the use of liquid chlorine, and was the first to use this method.

In 1907 with no chlorinated water-supplies, the typhoid fever death rate in the registration area of the United States Census Bureau was 30.3 per 100,000, with an estimated number of deaths in the entire country of approximately 30,000 for the year. In 1917 the United States Public Health Service reported that the rate had dropped 12.3 per 100,000 with an estimated number of deaths of 13,000, and at that time there were about 2,000 chlorinated public water-supplies. According to this, approximately 17,000 lives were saved from death by typhoid in that one year, effecting a saving of over \$125,000,000 annually.

The chlorination of public water-supplies is declared the cheapest insurance that can be obtained, the average annual premium amounting to about 40 cents per 1,000,000 gallons of water treated.

Vaccination as Health Insurance

The United States Public Health Service has issued health bulletin No. 7 of the *Keep Well Series*, under the title of "Vaccination—An Excellent Form of Health Insurance." It is written in the terse, simple English which gives the *Keep Well Series* a distinctiveness that other health bulletins often lack.

The Building Trades Council of Fresno, Cal., has endorsed plans for a clinic through which union men and their families will get medical attention at from \$1 to \$2 a month. A maternity hospital will be one of the buildings erected.

The number of limbs lost in American industry every year is 26,000. This is six times the number of amputations among American soldiers in the year of war. As soon as we have made peace in Europe, can't we do something to prevent the wounding of workmen at home?—*The Vocational Summary.*

¹ The paper by Doctor Hinton will be published in an early issue of MODERN MEDICINE.

THE NATION'S HEALTH

Public Health and Public Welfare, Administrative Medicine, Organized Health Service

C. E. A. WINSLOW, DR. P. H., *Editor*

THE VISITING NURSE ASSOCIATION

ONE of the most striking features of the public health campaign in the United States during the past twenty years has been the development of visiting, or district, nursing organizations. Since Miss Lillian Wald, with a single companion, established what has grown into the Henry Street Nursing Settlement, the part played by the district nurse in the treatment and in the prevention of disease has steadily increased. To-day in most cities visiting nurse associations care for far more sick patients than do the hospitals; while in many cities the visiting nurse organization through its infant welfare and anti-tuberculosis work carries on a larger share of the really effective preventive health work of the community than is borne by the health department,—officially charged with such duties, but sometimes more concerned with the routine inspection of back yards and food stores than with the actual prevention of disease.

It is no uncommon experience for the sanitarian to find that a given city with an undeveloped health department has an admirable record in infant mortality and tuberculosis as a direct result of the activities of a privately supported district nursing organization which has stimulated the establishment of the necessary clinics and dispensaries under its unofficial auspices.

The development of these visiting nurse associations has been so gradual and so free from self-advertisement that the wider significance of the movement as a contribution to health organization is likely to be overlooked. To-day it seems clear that the visiting nurse association constitutes a piece of administrative health machinery which is not only invaluable in itself but may teach us lessons of profound importance in the greater task of making the science of medicine fully effective for the prevention as well as the treatment of disease.

There are three fundamental problems which

confront the health officer and the thoughtful physician who desires to see the possible fruits of modern medical science fully garnered: the organization of the medical profession within itself so that the various types of clinical specialists, with the diverse laboratory facilities which they require, may cooperate effectively; the development of some plan by which medical service may be so easily obtained by the poor that financial considerations will not delay recourse to the physician until it is too late for his service to be effective; and the intimate blending of prophylaxis and therapeutics, without which either must fall short of its full potentialities. All of these problems had their parallels in the nursing field, and all three have been solved by the best of our visiting nurse associations.

The problem of specialization is of course very much less acute in nursing than in medicine; yet it is significant that in a well developed district nursing association we find infant welfare nurses, obstetrical nurses, tuberculosis nurses, orthopedic nurses, mental hygiene nurses, and communicable disease nurses,—all cooperating with each other and often with a general district nurse, who carries on the routine with the counsel and assistance of the specialists as consultants. Here is a type of organization which in its more restricted field accomplishes results analogous to those which are visualized by the proponents of group medicine.

The second problem, that of furnishing care to all who need it, irrespective of financial ability, has again been admirably solved by the district nursing organization. The service of a nurse is always at the disposal of the poorest patient without charge, while those able to pay for the care that is furnished are expected to do so, up to the actual cost of the service which is between fifty cents and one dollar a visit. The organization of a staff which is kept fully occupied all the time makes it possible to reduce the

actual cost to a reasonably low level, and the service supplied to those unable to meet this cost is paid for by some form of public subscription. It is fundamental, however, in the spirit of all good visiting nurse associations that the service given to the poor is not a charity but a duty which the community owes to its citizens; and it seems more business-like to present the cost of such service frankly, as a bill which the more prosperous and public spirited section of the community must assume, than to follow the course of the physician who bears the burden of free service to the poor himself, and then shifts a variable portion of the load upon the shoulders of individual wealthy patients.

Finally, the visiting nurse combines the care of the sick with the teaching of the laws of hygiene in a peculiarly interesting and significant manner. It is true that there are health officials who disapprove of this combination and who question whether the "visiting nurse" is or should be a "public health nurse" at all. This viewpoint is based on the fear that the urgent demands for the care of the sick may crowd out such educational work as is carried on by the public health nurse employed by a health department for this purpose alone.

Practical experience in many places, however, shows that such apprehension need not be justified. The staff of a well organized visiting nurse association does not, as a matter of fact, neglect hygienic instruction but carries it on far more effectively than any one who comes from outside with a purely abstract message. The intimate knowledge of physical and sanitary and social conditions gained by the visiting nurse makes it possible for her to offer, as no one else can, the instruction which a given family needs to get well and to keep well; and the gratitude earned by her direct services in the relief of suffering opens a door for a reception of her teaching which no didactic teacher of hygiene is likely to discover.

The difficulties of medical organization are in many respects more complex and more grave than those which have surrounded the development of the modern district nursing association. It is not to be assumed that any closely similar procedure can be applied in the two professions. Yet the same problems of mutual cooperation, sound financial support, and an infusion of the preventive spirit, which the nurses have solved so successfully, must in the future be met by the physician in his own professional field.—EDITOR.

A sixteen weeks' course of training in public health nursing, embracing both theoretical and practical work, has been opened in the University of Buffalo in coopera-

tion with the local department of health, the department of hospitals and dispensaries, the district nursing association, and the Chapter of the Red Cross, beginning September 29 and closing January 31. Students completing the course will be given certificates. Applicants must be registered nurses in New York or other states with satisfactory qualifications.

Report of Notifiable Diseases

The Public Health reports for August 15, 1919, give the summary for 1918 of the notifiable diseases in all of the states during the year 1918. The diseases reported are: Anthrax, Cerebrospinal Meningitis, Diphtheria, Influenza, Malaria, Measles, Poliomyelitis, Pneumonia, Scarlet Fever, Smallpox, Tuberculosis (pulmonary), Tuberculosis (all forms), Typhoid Fever, and Typhus Fever.

OHIO CONDUCTS EXTENSION COURSE FOR PUBLIC HEALTH OFFICIALS

An extension course in public health organization, administration, and preventive medicine, designed to afford an opportunity to physicians desiring to qualify under the Hughes Law of Ohio for positions in the public health service of that state, has been established under the administration of the Ohio State Department of Public Health and Sanitation, and the College of Medicine of the Ohio State University.

The course was begun September 17 and will continue three months. This three-months' extension course is offered to meet the needs of the state in securing health officials in the 102 health districts created by the Hughes health district bill. Appointments to these positions will be by competitive examination under the Civil Service Commission of Ohio.

The new course is not offered as a substitute for the full one-year course in Public Health and Sanitation given by the Department of Health and Sanitation, College of Medicine, Ohio State University, but is intended only to meet the present situation.

No admission fee will be charged. The course is open to graduates of recognized medical schools, graduates of recognized schools of public health, and to persons having at least one year's practical experience in public health work, subject to approval by the Executive Committee representing the state and college.

All courses will be given with reference to Ohio conditions. The details of the course are as follows:

Public Health Organization:=18 hours.

A discussion of the place of public health work in community life—the cultivation of community resources—the value of community education in specific problems—how to utilize community volunteer effort.

Public Health Administration:=36 hours.

The organization of national, state and local health departments; sanitary law and legal powers and responsibilities of health officers and boards of health.

Preventive Medicine:=36 hours.

The important facts and fundamental principles in preventive medicine are given consideration. Special attention will be given to the methods and procedure for preventing the occurrence of the communicable diseases as well as the control of this group of diseases. The non-infectious diseases will also be discussed from the standpoint of preventive medicine and the public health.

Public Health Problems:=30 hours.

This course includes an elementary consideration of the various public health problems which present themselves. Consideration is given to personal hygiene; vital statistics; epidemiology; the prevention and control of epidemics; sanitary engineering—water supplies, sewage disposal and plumbing; the public health laboratory; tuberculosis; child hygiene, physical supervision of school children; venereal diseases; occupational diseases and industrial hygiene; hospitals; dispensaries and clinics; public health nursing.

Instruction will be given by members of the faculty of the Department of Public Health and Sanitation, College of Medicine, Ohio State University, and by members of the staff of the State Department of Health.

ROLE OF VENTILATION IN PREVENTIVE MEDICINE

BY GEORGE TRUMAN PALMER, CHIEF OF INVESTIGATING STAFF, NEW YORK STATE COMMISSION ON VENTILATION

THE cold season of the year is approaching. We shall soon turn our backs on the seashore and begin building furnace fires. Screens will come down, the windows will close, and heavier clothing be donned. From our present outdoor existence we shall pass to a life indoors.

Coincident with the cold season and this altered mode of living we may expect people to die faster. For every 100 deaths in August, there will be 107 in December, 117 in January, 108 in February, and 120 in March (Chart I).

Chiefly responsible for this excessive winter mortality are the diseases of the respiratory tract. The indications are that during the coming autumn and winter, for every 100 people dying from pneumonia¹ during August, there will be 120 dying from this cause in September, 190 in October, 282 in November, 447 in December, 560 in January, 476 in February, 535 in March, and 414 in April. The sum of the deaths from November to April inclusive is 2,714. This is four to five times the number that would occur if the August rate prevailed (Chart II).

Combination of Causes Seen

There are several reasons for an increased amount of sickness in the winter. In the first place, the body is laboring under a greater strain. More heat is being produced, and to provide this heat the intake of food is increased. The digestive tract has more work thrust upon it. More oxygen is utilized to convert food into heat. Because of increased food consumption and the reduction in skin elimination of waste material through perspiration, the kidneys are called upon for increased effort. Body wear and repair are heightened. In short, the metabolic turnover is greater in cold weather.

In the second place, resistance to infection of the respiratory tract is lessened by cold and over-heating. The circulatory system must adapt itself to a wide range of temperature—from the

PERILS OF INDOOR DISEASES

For every 100 deaths from pneumonia in August there are 535 in March.

Bad ventilation is the most sinister influence at work during the winter and this is largely a matter of over-heating. Our powers of accommodation are not well adapted to high temperatures.

Shall we continue to make conditions right for disease and by our lack of ventilation render the bodily mechanism abnormally susceptible?

Or is it possible for the American people to acquire the cool air habit?

seventies indoors to the thirties and lower out of doors. Unless the vasomotor system responds efficiently to these external variations, there is an undue loss of heat from the body, or else an accumulation of heat, and either the lowering or raising of body temperature a degree or so from normal is fraught with danger.

Thirdly, it is easier to contract infection in winter, for more people have coryza and colds,

which necessitate increased use of handkerchiefs, and consequently pollution of the hands with infectious material is more common. There are also more coughing and sneezing, which spread infectious matter to people in the immediate vicinity.

The problem of lessening the winter mortality is thus one of modulating these aggravating factors, and practices which strain and tax the body unnecessarily must be avoided. Every effort must be put forward to keep the body fit.

We can increase vasomotor tone by cold baths and outdoor exercise. We can also strengthen our resistance to cold by living in cool atmospheres and avoiding over-heated rooms. This brings us to a realization of the importance of ventilation in maintaining health.

Remove Unnecessary Strain

Bad ventilation, and by this term we refer chiefly to over-heating, for this factor is the most sinister of all, imposes an unnecessary strain upon the body mechanism, and over-heating is the rule rather than the exception in our habitations during the cold season.

Let me review briefly the conditions which commonly prevail during the hibernation period of the year.

Indoor temperatures in our homes range from 70° to 75° F., and over. It is the exception to find temperatures below 70°. Most people find this cooler atmosphere chilly, which is *prima facie*

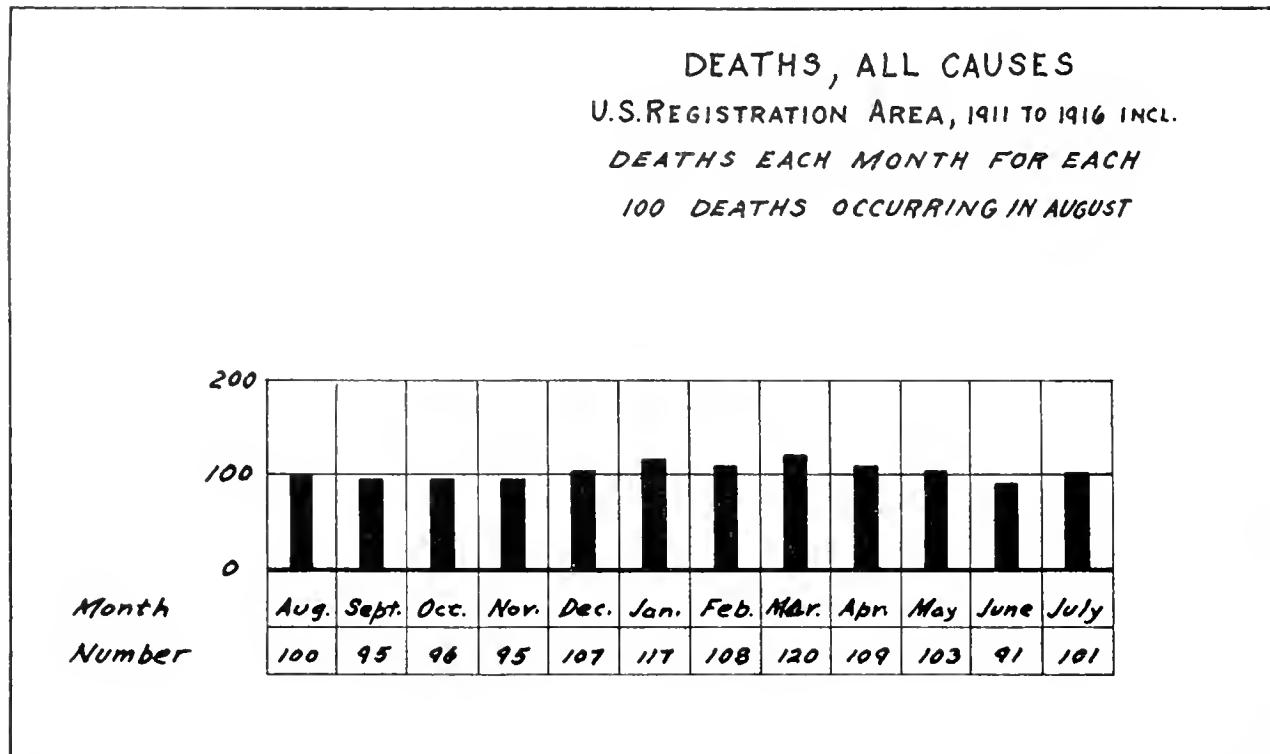

¹. United States Registration Area 1911-1916. Pneumonia (all forms).

evidence of the fact that these same individuals are used to higher temperatures. To find the cooler indoor temperatures it is necessary to go out into the sparsely settled districts, where coal is less readily obtained, where some rooms are not heated at all directly, and where each journey through the hall, or each trip upstairs, means a plunge into a temperature bordering around 60°.

Business offices are over-heated. As a rule it

mometer. From an initial temperature around 68°, the temperature soon rises, after people have assembled, to 75° F. and even 80°. From this "stuffy" atmosphere, which is nothing more nor less than an over-heated atmosphere, people go forth with enlarged turbinates and congested skin, a fertile field for respiratory infection. Club "smokers," amateur entertainments, illustrated lectures, and convention meetings are so

CHART I

The above chart presents data from the United States Registration Area, 1911 to 1916, which show the toll in human life exacted because of our indoor habits of winter.

is no one person's business to watch the thermometer and no one does until the mercury passes 75°, and by this time much of the evil effects have been experienced. The male sex, dressed in heavier clothes, is usually the first to complain. Women workers, clad in lighter weight clothing, find 75° atmosphere rather comfortable. In a room in one of the Government office buildings in Washington, occupied by thirty or more clerks, thermometer readings were made several times daily during the first four months of 1919. Eighty-six per cent of the readings were over 70° and 44 per cent over 74°. Only 14 per cent of 508 readings were within a temperature range recognized as desirable, namely, 65° to 70°.

The assembly hall or room large enough to accommodate from twenty-five to one hundred people unprovided with special ventilating equipment is a flagrant example of over-heating. Here, again, it is no one's business to watch the ther-

frequently held in over-heated rooms that it is a rare exception to find the contrary. I have known people to stay away from these gatherings rather than expose themselves to the discomforts of poor ventilation.

No Escape from High Temperatures

Theaters of all types are over-heated rather than otherwise. The temperature is usually comfortable at the beginning of the performance but, as happens elsewhere, heat builds up as time passes. The writer made observations in five large theaters in New York City during winter weather and found temperatures from 70° to 80°. In only one of the five did the temperature fail to rise above 72°.

Department stores are usually over-heated. Starting off in the early morning with temperatures around 68°, these places soon accumulate heat from the bodies of many shoppers within

and the sun without. It is not long before the over-coated shoppers and even the uncoated clerks feel uncomfortably warm. The shopper can find relief by leaving. The clerk must remain and nurse the discomfort and look forward hopefully to the hour for closing.

Railway and Pullman coaches are rendered so uncomfortable by high temperature as to make one detest traveling in winter. I wonder if any of the readers of this article have boarded a sleeper in the evening in South Station, Boston, bound for New York, and have gone to bed thinking to get some sleep before the train pulled out at 1 a. m. It has been my experience to do so upon several occasions and to lie there perspiring in an atmosphere of 80° only to waken several hours later thoroughly chilled, the temperature meanwhile having fallen to the fifties or below.

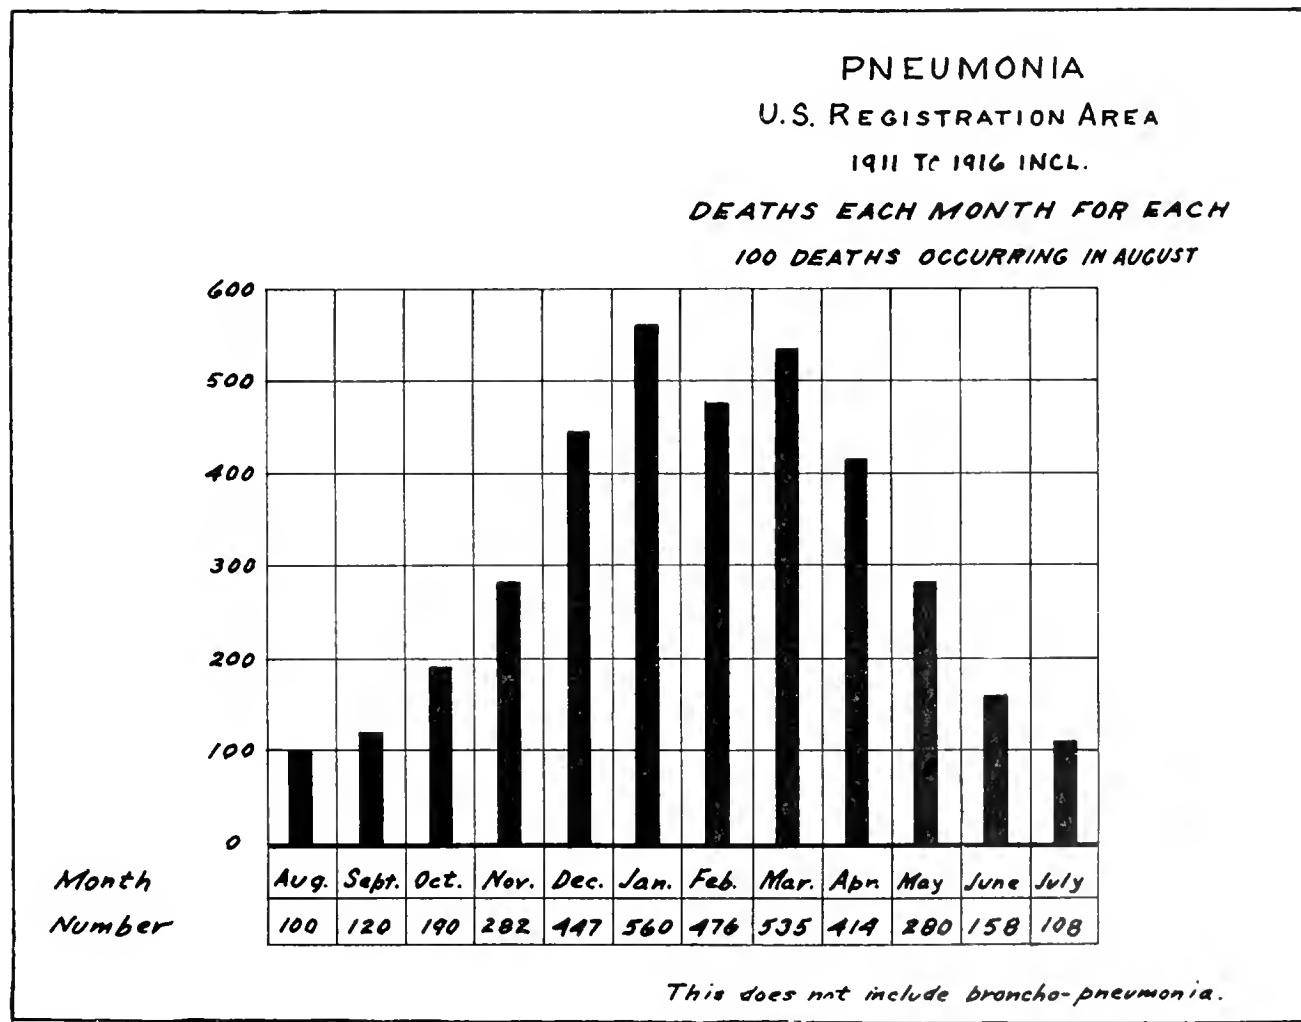

Instances of over-heating in factories, hospitals, and schools are all too common. In some industries there is an excuse for high temperatures. In the other places mentioned there is

none. For five months of the year, from October to April, fully 75 per cent of the waking hours are spent within doors. It is of supreme importance, therefore, to render the air environment of this indoor life non-aggravating.

Heat Worse Than Waste Products

Bad ventilation is purposely referred to in terms of over-heating because high temperature is the dangerous element in ventilating. It is true that there are more carbon dioxid and other products of human exhalation in the crowded room, but the body is amply equipped to meet natural changes in the chemical composition of the air and is not injured by such contact. The odors of crowded rooms are disagreeable but not harmful. There is more dust in congested rooms, but the body unaided is able to meet this element. There are more bacteria to be found in dusty air but they are of the harmless variety. There is less moisture in indoor air in cold weather, and this is irritating if combined with high tempera-

CHART II

The relative mortality is greater when respiratory diseases only are considered. The normal rate in August is less than one-fourth of the death rate in March.

ture. If the temperature is maintained between 65 to 70°, there is neither discomfort nor any indication of harm from the naturally low relative humidity. The objectionable factor in bad ventilation is a thermal one; as chilling temperatures are so uncommon, bad ventilation is largely a matter of over-heating.

High indoor temperatures are generally recognized as uncomfortable, but the case against over-heating is further supported by painstaking scientific experiment, and we do not need to resort to temperatures of 80° and 90° to demonstrate detrimental effects on the body.

Effects of Slight Changes

The New York State Commission on Ventilation has shown that a change even as slight as from 68° to 75° produces in a very short time a visible reaction in the body mechanism. In a 75° atmosphere the pulse in one series of experiments rose from 79 in the morning to 89 in the late afternoon, an increase of 10 beats per minute. At 68° the pulse rate of the same subjects fell from 83 to 70 in the course of the day, a drop of 13 beats. The warmer room thus placed upon the heart the added strain of 23 beats per minute. Even this increased heart action was unsuccessful in lowering body temperature. The normal change at 68° was a drop during the day from 98.82° to 97.74°. In the warmer room there was not a fall but an actual rise from 98.25° to 98.63.²

The above result occurred when the subjects were for the most part inactive. When vigorous physical work is done a somewhat modified result is observed in heart action and in temperature. In this instance the following average readings were obtained:

PULSE RATE PER MINUTE			
	9 a. m.	3 p. m.	Increase
68°	73	77	4
75°	75	78	3
BODY TEMPERATURE (FAHRENHEIT)			
	9 a. m.	3 p. m.	Decrease
68°	98.58	98.11	0.47
75°	98.69	98.53	0.16

The pulse rate is seen to increase almost the same amount under both conditions. Body temperature has fallen 0.47 degrees in the cool room, and 0.16 degrees in the warm room. These experiments suggest that the body at exercise is better able to cope with slight over-heating than when at rest. Exertion causes the body to perspire freely and in this manner heat is dissipated. The sedentary person is apparently just below the critical point where perspiration furnishes an outlet for excess heat; consequently, body temperature increases.

The dangers arising from the unnaturally over-

heated body are indicated by experiments the Commission performed with animals. They found that, as contrasted with control animals at normal temperatures, those exposed to warm atmospheres showed a reduction in the aggressive action of the blood against foreign bodies. Over-heating was coincident with diminished formation of agglutinins and precipitins, and in hemolyzing activity. The significance of this is that over-heating produces a lowered resistance and renders the body more susceptible to infection. It will be remembered that many years ago Pasteur produced a similar result, making immune animals susceptible to anthrax by reducing their resistance through chilling.

There are undoubtedly other changes which occur in the over-heated blood and of which we have as yet no exact knowledge. There are optimum temperatures for each form of plant and animal life. The egg will not hatch if the temperature of the incubator is too high or too low. Vital processes are interfered with by deviations from the optimum temperature. We can readily conceive of metabolic processes being disturbed by slight unnatural temperature deviations in the human body. Is it not possible that waste products in congested areas become toxic or that food assimilation is retarded and that the process of tissue repair is delayed? It would seem as if some such explanation were necessary to account for the feeling of lassitude and uncomfortable after-effects of exposure to high temperature. Is it not possible also that physical exercise moderates this effect through compensatory changes in rate of blood flow, movement of lymph, and removal of the products of combustion?

Thermal Comfort Essential

To be sure, man can accommodate himself to a wide range of temperature, more so than any other form of animal life. This power of accommodation is, however, better adapted to deal with low than with high temperatures. In summer, the body being lightly clad, can cool itself readily by means of perspiration. The skin is more accessible to air currents. In winter the body is heavily clad and cooling of the skin surface is retarded by the clothing. Matters would be simplified if we could remove clothing down to the point where thermal comfort is re-established, but this is impracticable in many cases, particularly among sedentary office workers and store clerks. Thus the regulatory action of the body in disposing of heat is handicapped in over-heated rooms in winter and the handicap is more serious

². These are averages of numerous readings of rectal temperatures, and explain the result carried to the second place beyond the decimal. Thermometers were read to the nearest tenth of a degree Centigrade.

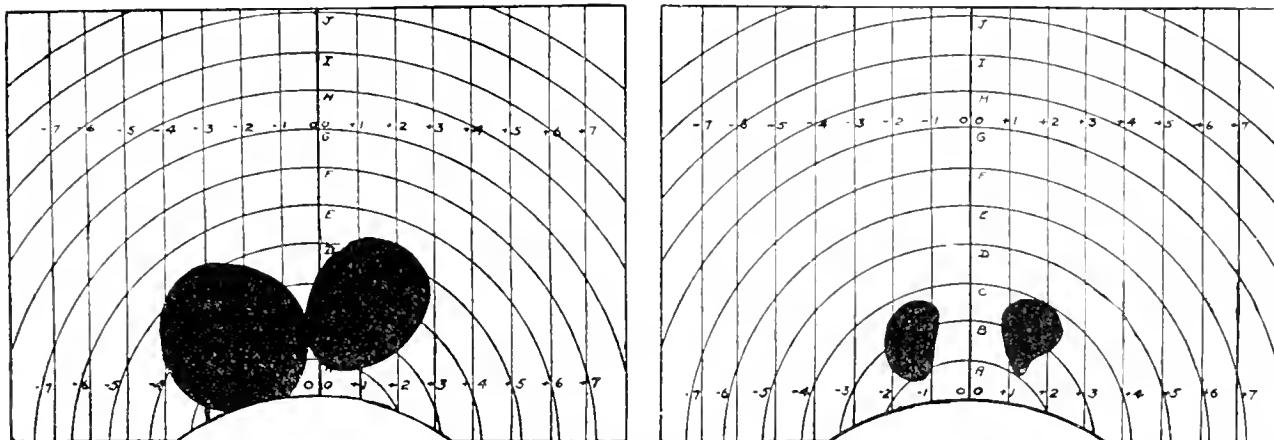

to the sedentary person than to the man physically engaged.

Furthermore, over-warming causes congestion in the nose, and reduces the size of the breathing aperture. The illustration (Chart III) shows a method of following the changes in the nose in the presence of heat. It is common knowledge

in a theater to maintain coolness, but quantity alone, without coolness, will not answer the purpose.

The ends of good ventilation have not been attained when the anemometer registers a standard flow. It is immaterial if 30 cubic feet of air per minute are being forced through a room so

CHART III

Relative size of breathing aperture at normal temperature and after a stay of a few minutes in an over-heated room. The black areas represent moisture-covered space on a cold, polished metal plate held before the nose.

that constriction of the breathing space is frequently coincident with or precedes coryza; this in turn means more frequent blowing of the nose, and increased pollution of the hands.

Granted that the over-heated room is an undesirable feature of our daily life in winter, why is it that we fail to act on this knowledge?

Inaction Accounted For

There are four reasons which may be offered. In the first place, over-heating occurs because many people, though conscious of the discomfort, are ignorant of the subtle possibilities for harm. In the second place, the enlightened public who have been informed of the dangers of bad ventilation do not believe. They may subscribe to this doctrine publicly but privately there is a lurking doubt or only a half-hearted appreciation of the danger. Thirdly, there is a mistaken conception of ventilation. In the most commendable campaign for fresh air waged in recent years attention has been centered on quantity and chemical quality of air rather than on its physical attributes.

Fresh air primarily is cold air. Increase the temperature and freshness vanishes. This statement is supported by experimental evidence. We must reverse the order of these ventilation factors. Of first importance is coolness. Secondary to this are quantity and quality. These factors should be inseparable. As it happens they are frequently divorced. Air quantity is necessary

long as the temperature is 75°. In other words, aeration should be looked upon as a means to an end. The end is coolness. The thermometer and not the anemometer should be the guiding register. This is frequently the error of the ventilating engineer. It is difficult for him to understand why a ventilating system is not a success

Method of making the nose-aperture measurement shown in Chart III.

when he has assured himself that the number of air changes per hour is up to standard.

The fourth point we wish to make is that the public is unfamiliar with the methods of preventing over-heating. We naturally associate heating and ventilating. We must learn to associate cooling and ventilating. Our domiciles and

work-rooms start out at comfortable temperatures, but they accumulate warmth during the course of the day. What we must do, and have not done, is to take cognizance of the natural sources of heat. This can be done by running furnaces at a constant rate and carrying off the excess heat of industry and occupancy and from the sun by increasing the air flow; or it can be done economically by checking the output of artificial heat and actually utilizing the natural sources of heat.

The necessity for some such reduction in the artificial heat output in order to maintain comfortable temperatures may be appreciated from the following illustration. The large hall or theater is equipped with approximately a square foot of radiation for each one hundred cubic feet of space. One square foot of surface on the low pressure steam radiator gives off about 250 B.t.u. per hour, an amount comparable with the heat output of the average occupant in the audience. When the theater is filled so that there is one person to each one hundred cubic feet of space, the audience is producing as much heat as the steam radiators. There is twice as much heat being given off within the room when filled as when empty. Theoretically, if all artificial heat were cut off when the theater is fully occupied the temperature would remain the same as before occupancy. In this calculation no allowance has been made for heating the air used in ventilating, but still the illustration is sufficient to show the main cause of over-heating, and this is applicable to department stores, factories, schools, and offices, as well as to theaters.

Cool Air Campaign

To eliminate over-heating it will be necessary to project an earnest organized campaign against it. The occasional and random issue of health board manifestos on the subject are insufficient. We must look to the health officer and the family physician to lead the charge. The American people lack the habit of living in cool rooms. They must be encouraged to cultivate this habit. The health officer can:

- (1) Give publicity to a ventilation standard of 65° to 70° F. for those in sedentary occupations.
- (2) Strive toward the elimination of over-heating in public places through publicity, ordinances, and inspections.
- (3) Encourage the use of a thermometer as an indicator of good ventilation.
- (4) Stimulate the cool room habit in private places by publicity and inspection.

The family physician can render a service in

the home through friendly suggestion expressed with conviction. He can tell the head of the house that cool atmospheres will tend to remove some of the aggravating causes of nose, throat, and lung weakness, and give arteries and kidneys a better chance to function properly. The American citizen cannot fail to be interested in measures which will lengthen his life and make him more efficient and more cheerful in the living of it.

The family physician can tell the employer of an experiment conducted by the New York State Commission on Ventilation in which 15 per cent more physical work was performed by a group of men in an atmosphere of 68° than when working in one at 75°. This experiment was not of the impractical kind, but on the contrary it was conducted with the factory and office employee in mind. The subjects of the experiment were young men who were paid a weekly wage. A portion of the day was given over to the lifting of dumb-bells. A bonus in addition to the wage was paid for this work. By working assiduously a man could increase his daily pay by 50 per cent or more. He was not compelled to work. His regular wage would continue whether or not he touched the dumb-bell. The bonus was sufficiently large to be worth obtaining and yet not large enough to induce him to work if he did not feel like it. In other words, this test was a measure of his inclination to work. The result showed that his inclination to work was 15 per cent greater in a cool room. When you ask the employer to prevent over-heating you are not thus appealing solely to his good nature. You are giving him sound business advice.

The most difficult attack in this campaign will be against the places of amusement. You cannot insure increased patronage to a theater solely by good ventilation. There is no use in deceiving ourselves into the belief that good ventilation with a mediocre attraction will draw patrons away from a badly ventilated theater with Mary Pickford as the drawing card. People go to the theater primarily for entertainment. If the brand of entertainment is equally good at two places, the one with the better ventilation eventually will show the more receipts; but entertainment will be had, ventilation or no ventilation.

Theater and auditorium ventilation must be improved through municipal ordinances and through public sentiment. If the public develops the cool air habit in home and office, it will not be long before its wants reach the ears of theatrical managers and then results will follow quickly.

There are many mechanical and structural de-

tails which must be observed in combating the over-heated room, but these are matters which cannot be touched upon here. The first step in this campaign is to develop a "cool air conscience." The mechanical features are not complicated and will be forthcoming when the demand is great enough.

Good ventilation is worth while. The sooner we utilize our knowledge of the subject the sooner will be the return. Good ventilation alone will not make us all live to a ripe old age. It is not a solution for all labor troubles. It may not have the slightest effect in preventing such specific

infectious diseases as measles, scarlet fever, or diphtheria, which attack the susceptible and evade the immune. Let us not be unreasonable in our prophecies. Exaggeration will only lead to disappointment and distrust. Preventive medicine can build stronger if it recognizes its own limitations. What we can promise is increased indoor comfort, a lessened number of infections of the respiratory tract, better health, the prospect of a longer life, and increased physical efficiency. These attributes are a sufficient incentive in themselves for acquiring the cool air habit. It is unnecessary to claim more than this.

NEIGHBORHOOD ORGANIZATION VS. TUBERCULOSIS

BY N. A. NELSON, SUPERINTENDENT, CINCINNATI ANTI-TUBERCULOSIS LEAGUE, CINCINNATI, O.

SLOWLY, it is true, but surely nevertheless the interest and cooperation of the individual citizen is being sought and gained in the solution of problems of public welfare. And just as surely as those problems vary with the nature of a community, even to as small a unit as a city neighborhood is their solution to be found only in the interest of the citizens of the neighborhood in them and their acceptance of responsibility for them.

Two factors are responsible for the realization that this is the time to gain the attention of the citizen to problems of public welfare; that in the neighborhood are to be found the peculiar phases of those problems as they more acutely affect him; and that their 100 per cent solution can be approached only through the full cooperation of all the elements of the community.

Direction of New Efforts

The first is to be found in changes which are taking place in the field of public welfare itself. Public health and social service agencies, in their struggle for existence, have been concentrating their efforts in the advertisement of their accomplishments in terms of quantity in an attempt to secure public recognition and funds. Little time has been devoted to analyses which would demonstrate the quality of their services in terms of value and results to the recipient, or as to how they might be improved. Now that the need for these organizations is generally conceded by the public, and their existence is assured, more time and thought is being put into improvement of service.

This has led toward cooperation between groups of agencies. The nature of this cooperation is demonstrating itself in several ways: financial

federations, coordinating councils to prevent overlapping of work, case committees, common districting by groups of agencies, the health center and the community center all represent an effort on the part of agencies to cooperate.

Even this improvement of service failed to bring the agency into contact with the large, unreachèd portion of the public needing its services. It failed, furthermore, to secure the interest and cooperation of the whole public either as a body or in terms of individual citizens who are, after all, directly or indirectly affected by the problems of some of them. It was then that some social workers came to the realization that the most essential party to full cooperation had not been considered, *i. e.*, the object of their efforts, this same public. Thus we have come to the idea of neighborhood organization.

The second factor is the world movement toward a democracy which will give the individual a real interest and a real responsibility in the affairs of the community, the state, and the nation. Prussianism is doomed, not alone in national affairs, but in the management of the smallest civic enterprise; and thus, together with the natural development in the field of public welfare has come the spirit of democracy which demands that the people play a part in the solution of their problems.

Aiming at Civic Unity

Neighborhood organization can and should accomplish several ends not possible under the old form of general organization. Roughly outlined they are:

(1) To secure the interest and cooperation of all of the elements of the neighborhood in the discovery and study of public problems as found

in the neighborhood. Neighborhood elements should include the professions, business, medical, sanitary and social services, schools, churches, and civic bodies, as well as the private citizen.

(2) To educate the neighborhood to a realization of the importance of those problems and the means for their solution.

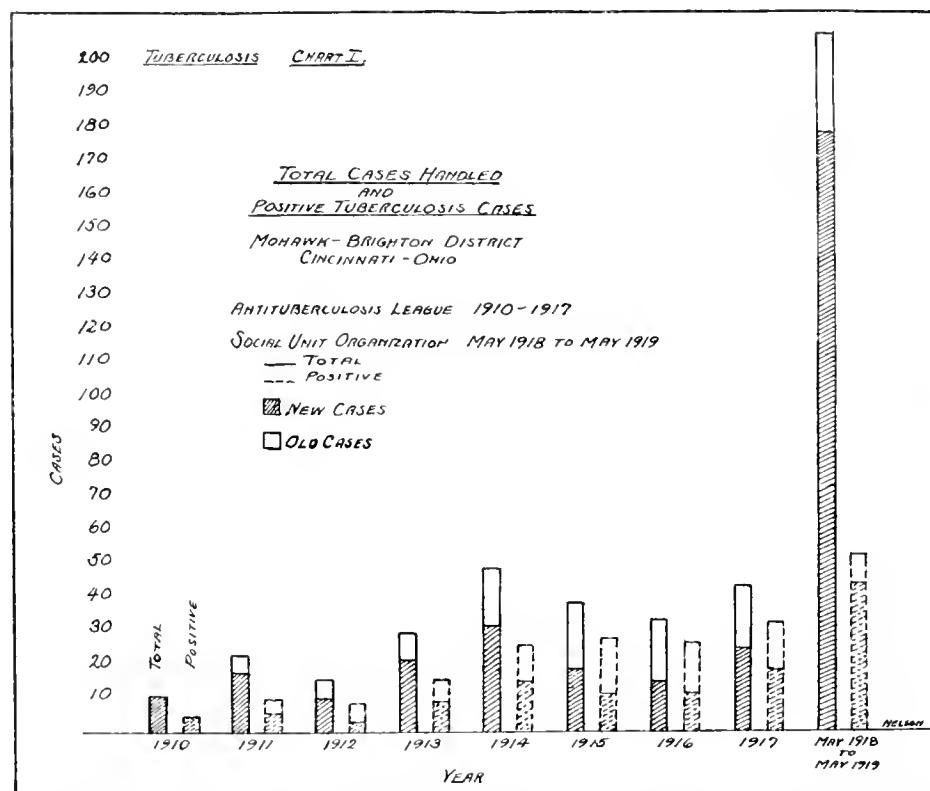

(3) To do 100 per cent work upon those problems. This should include 100 per cent baby registration, 100 per cent physical examination, 100 per cent discovery and care, not only of the tuberculous, but of the potential tuberculous, etc.

Neighborhood Organizes for Real Work

In 1917 the Cincinnati Anti-Tuberculosis League through the Municipal Tuberculosis Committee, organized by Mr. Courtenay Dinwiddie, then superintendent of the League, realizing the importance of community organization, had developed plans for a neighborhood health center through which these objects might be attained. At that time its attention was called to the plan of the National Social Unit Organization. Believing that the latter was capable of even further development than their own, the Unit plan was presented to the people of Cincinnati, largely through the efforts of Mr. Dinwiddie and of the Municipal Tuberculosis Committee, headed by the late Dr. John H. Landis, then health officer, and strongly supported by Mr. William J. Norton, director of the Council of Social Agencies. It was given a reception which brought the Unit to Cincinnati in the face of more or less strong competition on the part of fifteen other cities, among them Washington, Baltimore, Cleveland, Minneapolis, St. Paul, Kansas City, Den-

ver, Newark, New Haven, and Providence. Decision as to the district in which the plan should be tried was left with the people of the various sections of the city and the overwhelming response from the Mohawk-Brighton District left no other choice to be made. The Social Unit Plan has been the subject of many conference papers and publications. It is well known and is being followed and studied closely by leading men and women of the country, hence a detailed account of it is not necessary here. It is being carried out in a neighborhood of some 15,000 inhabitants in a representative section of Cincinnati. The Unit is divided into thirty-one "blocks" of approximately 500 inhabitants each. Each has a council elected by the residents of the block over 18 years of age. This council elects an executive

CHART I

The increase year by year of cases handled is to be noted. Total cases handled have increased 373 per cent; new cases, 616 per cent; positive cases, 65.6 per cent; and new positive cases, 144 per cent. A tabulation of the data appears in the accompanying table.

TABLE I
TOTAL CASES HANDLED, OLD AND NEW, POSITIVE CASES, OLD AND NEW, MOHAWK-BRIGHTON DISTRICTS:—
ANTI-TUBERCULOSIS LEAGUE, 1910-1917—SOCIAL UNIT ORGANIZATION, MAY, 1918, TO MAY, 1919.

Cases	1910	1911	1912	1913	1914	1915	1916	1917	May, 1918, to May, 1919

Old		4	5	7	11	17	26	14	9

*Total cases handled by League in entire city (1917), 3,088; (1918), 3,172.

These figures give a comparison, year by year, of the cases handled by the League and by the Unit. Chart I illustrates graphically the comparisons.

or "block worker" who represents the residents of her block on the Citizens' Council of the Unit. She visits the families in her section, keeping them in touch with the Unit, building up the Unit spirit, and bringing to the proper department of the organization their specific problems. She is paid \$4 a week for the time she loses from her household duties.

The Citizens' Council gives representation to the people of the district; an Occupational Council secures the interest and cooperation of the various occupations and professions; while the physicians, nurses, and social workers have their groups for the consideration of problems peculiar to their work. No new work is undertaken until it has the endorsement of the people of the Unit through their representatives on the various councils. The extent to which they are interested was fully demonstrated by a vote by the people of the district in April, 1919, of 4,034 in favor of the Unit, to 120 against it.

Most of the city welfare agencies are cooperating with the Unit, some to the extent of the full-time service of a worker. Among the latter agencies is the Anti-Tuberculosis League.

Anti-Tuberculosis League Cooperates

In May of 1918 the League sent one of its nurses to the Mohawk-Brighton District where she has since devoted her whole time. Instead of

The nurse from the Mohawk-Brighton Social Unit is welcome in many households.

specializing, however, in tuberculosis nursing she became one of a corps of five nurses doing generalized nursing, each of the five caring for the tuberculosis work in her district. All of the nurses regularly attend the clinics at the League dispensary, thus gaining valuable training and

Social Unit nurse measuring baby.

experience in this special field. Their cooperation with the League physicians whose dispensary still serves as a diagnostic center for patients from the Unit, gives them additional advantages in the handling of their work.

In the same way the League nurse is given experience and training in general nursing, child welfare and in neighborhood service. Both the League and the Unit benefit by this close cooperation and interchange of experience.

This relationship has existed a little more than a year and the purpose of this study is to determine what has been accomplished in the field of tuberculosis during the first year under the Unit plan of organization as compared with the work of the League in the district in previous years.

TABLE II
CASES REPORTED FROM SOURCES COMPARABLE TO BOTH ANTI-TUBERCULOSIS
LEAGUE AND SOCIAL UNIT, MOHAWK-BRIGHTON DISTRICT—ANTI
TUBERCULOSIS LEAGUE 1914*-1917—SOCIAL UNIT ORGANI-
ZATION, MAY, 1918, TO MAY, 1919.

Application to Sanatorium.....	6	4	3	9	9
Own accord	2	2	1	5

*Data previous to 1914 not reliable.

The study will be limited, of necessity, as far as clinical results with individuals are concerned, the time of handling by the Unit being too short to look for such results; but there are many factors relative to the quantity of the work done and its quality in general terms that make interesting and very valuable comparisons and allow of important conclusions.

With the nurse, the League turned over to the Unit in May, 1918, the 29 cases from the District which it was handling; of these, 9 were positive. By May 1, 1919, a year later, the Unit had handled 208 cases, 53 of which were positive. Of the 208 cases, 124 were still under care at that date, 31 of which were positive.

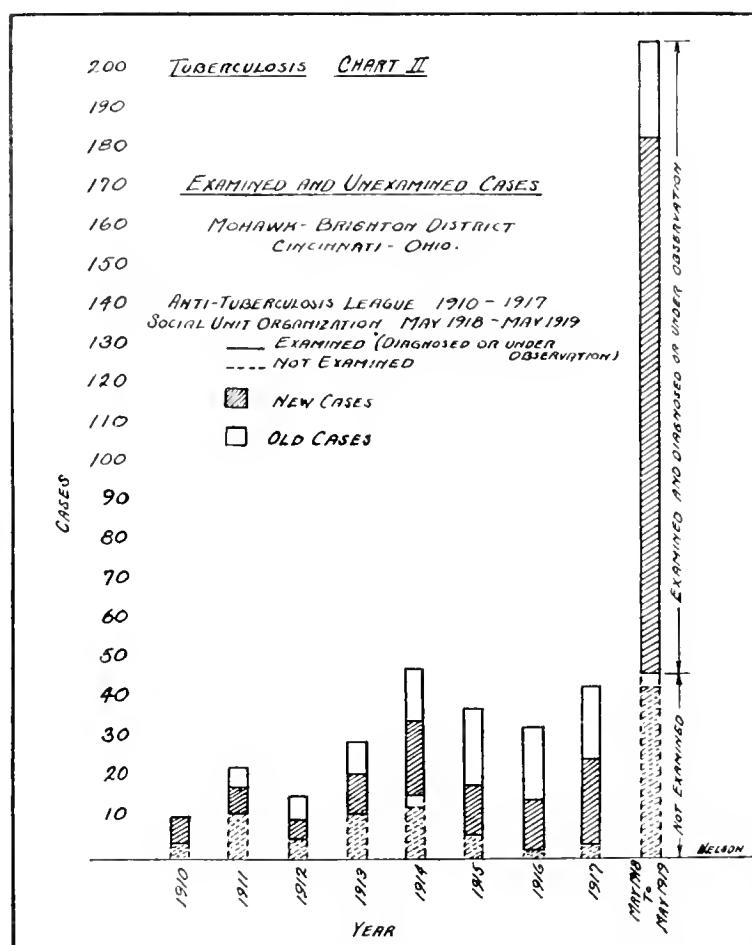

A comparison, by years, of the number of cases, new and old, handled by the League and by the Unit, as shown in Table I and in Chart I, is enlightening: The total cases handled have increased 373 per cent; new cases 616 per cent; positive cases 65.6 per cent and new positive cases 144 per cent.

Even these high increases may not represent the full possibilities of the Unit as it must be remembered that the Unit began with but 29 cases and built up, during the year this remarkable total. Now that the higher level of which the Unit is capable has been more nearly reached, the total number of cases for following years should be greater. Perhaps a fairer comparison would be in the number of cases still under care at the end of the year. Thus the 124 still carried by the Unit represent an increase over the League's 1917 record of 551 per cent, and a 417 per cent increase over the League's highest record of 24 for 1914. Similarly, the 31 positive cases still carried by the Unit are an increase of 182 per cent over the League's 1917 figure of 11, and 107 per cent over the League's high mark of 15 in 1916.

Of the 179 new cases reported, 103 were located by forces within the Unit itself. The general good will of the people toward the purpose of the Unit, the ability of the blockworkers to win the confidence of

their families, generalized nursing, child welfare work, and cooperation on the part of physicians are all factors in this increase, intangible and incapable of actual measurement, but nevertheless evident to anyone who has been in touch with the Unit. They are factors without which no amount of intensification of service could secure an opening into the homes of so large a number of families in so short a time.

CHART II

The relative proportion of work done, as shown in Table II is more clearly seen in this chart.

TABLE III
TOTAL CASES HANDLED CLASSIFIED ACCORDING TO DIAGNOSIS. MOHAWK-BRIGHTON DISTRICT:—ANTI-TUBERCULOSIS LEAGUE, 1910-1917—SOCIAL UNIT ORGANIZATION, MAY, 1918, TO MAY, 1919.

Diagnosis	1910	1911	1912	1913	1914	1915	1916	1917	May, 1918, to May, 1919
Not examined, not diag.	4	12	5	12	16	6	2	3	47
Examined, not diag.	1	1	1	1	1	1	1	19
Diag. Neg. Dismissed	1	1	1	1	1	1	17
Diag. Neg. Not dis.	1	1	2	2	1	3	47
Anemic	1	1	2	4	10
Pre-tuberculous	1	1	2	4	10
Non-pulmonary tuberculosis	1	1	2	2	2
Pulmonary tuberculosis—	1	1	1	1	1
Stage I	1	2	1	4	10	6	22
Stage II	2	5	5	11	22	20	16	25	31
Stage III	3	3	2	1	1	2	1	1
Pulmonary tuberculosis—	1	1	1	1	5
Unclassified	1	1	1	1	1	1	1	5
Total	11	23	16	30	48	39	34	44	208

The examined and unexamined cases are brought together in this table for comparison. The balance is again in favor of the Unit plan, which exceeds in each classification the highest number by the League. A graphic illustration of the data is provided in Chart II.

That the confidence which is so necessary to the successful entry into the home is a reality in the Unit, built up by the Unit form of organization, is attested by leading individuals and organizations in the city. The Council of Social Agencies says of it: "Unquestionably the Social Unit Organization has been able to develop a community consciousness in the Mohawk-Brighton District which has not been developed to the same extent in other districts of the city; a community consciousness which takes into consideration the happiness of all the people living in that district; a neighborliness which is highly commendable. The Social Unit Organization has created community machinery and a community spirit where an unprecedented proportion of the individuals needing health service have been reached by its preventive work."

Mrs. C. E. Sibbett, of the Sands Kindergarten School in the Social Unit District, writes: "The result of the nursing care provided by the Social Unit Organization to the small children of the Mohawk-Brighton District is very apparent. Through my visits in the homes of these children I have been able to see a markedly greater interest and intelligence about child care. I have noted general improvement in home conditions and a degree of cooperation which is exceedingly gratifying."

Dr. Randall J. Condon, superintendent of schools, in an address at a neighborhood meeting of the Social Unit, said: "I know of no other community where the people would express such an interest in their neighborhood affairs as you are doing in coming together for this meeting in such large numbers to discuss purely general problems and plans for the civic and social welfare of their neighborhood."

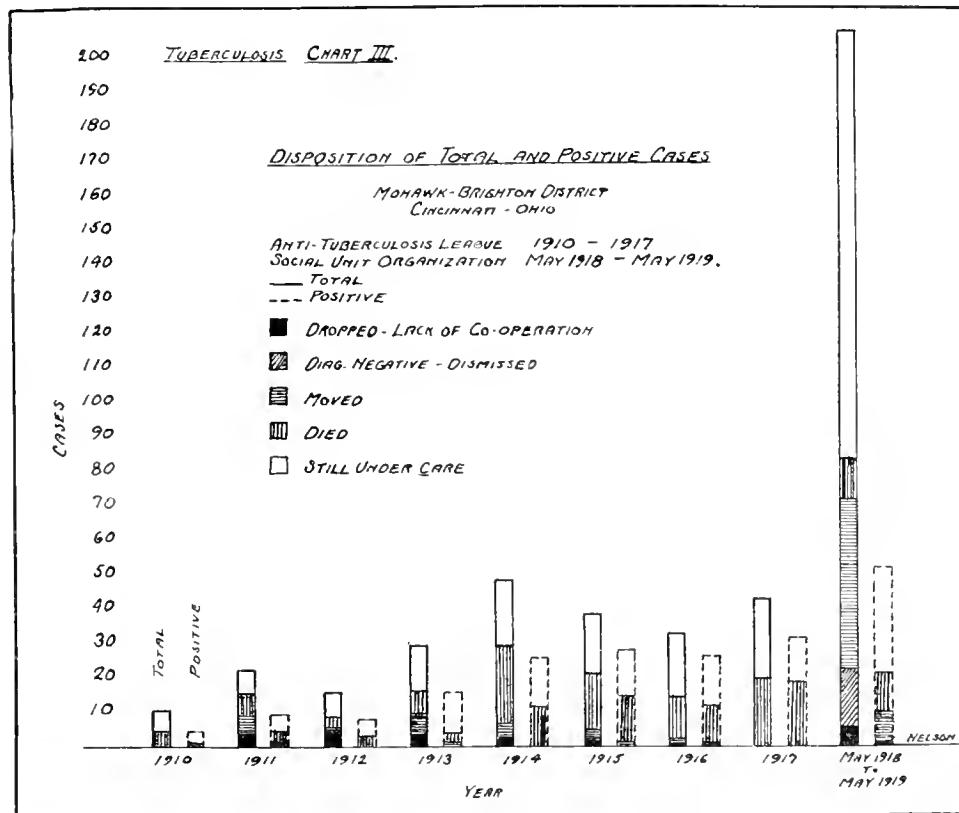

An increased number of contacts with sources ordinarily reporting cases to the League, is indicated in Table II.

A study of the examined and unexamined cases can be made from Table III and Chart II. Of the 47 not examined and not diagnosed, 43 are new cases, 18 of which moved before examination could be made, and 10 of which came under observation during the last four months of the year.

Of the 22 first-stage cases, 17 are new; 27 of the 31 second-stage cases are new; 3 new arrested cases have been found and are under observation.

The large group of 67 negative not dismissed, anemic and pre-tuberculous cases, of which 54 are new, represents a gratifying increase in the supervision of potential tuberculosis and thus in preventive work. Compared with the 8 handled by the League

CHART III

Losses of cases during the year, including diagnosed negative and dismissed, moved and not found, constitute 78% of the total lost; 18% of the total lost died.

TABLE IV

STATUS, AT END OF YEAR, OF TOTAL CASES HANDLED, MOHAWK-BRIGHTON DISTRICT:—ANTI-TUBERCULOSIS LEAGUE, 1910-1917—SOCIAL UNIT ORGANIZATION, MAY, 1918, TO MAY, 1919.

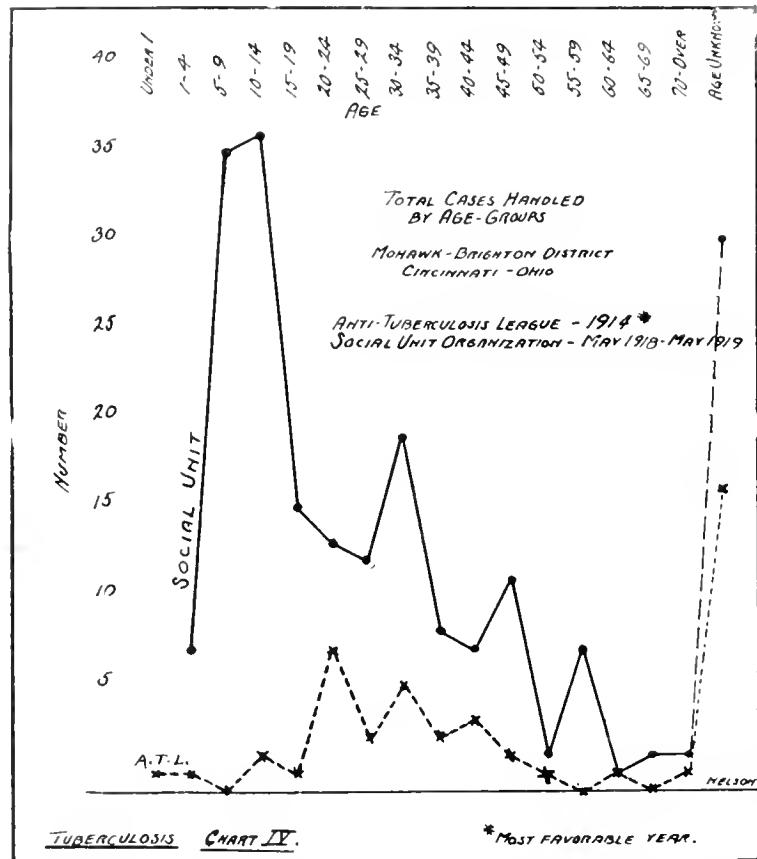

Status	1910	1911	1912	1913	1914	1915	1916	1917	May, 1918, to May, 1919
Dropped for lack of co-operation	4	4	4	4	3	2	1	6
Diag. Neg. Dis.	17
Moved	3	1	4	1	3	1	41
Not found	2	1	2	3	8
Dead	5	7	3	7	23	17	13	20	12
Still under care	6	7	7	13	18	17	19	24	124
Total	11	23	16	30	48	39	34	44	208

The status of cases at the end of year is shown graphically in Chart III.

in 1917, the highest of any year, it represents an increase of 575 per cent. The 19 examined but not diagnosed also undoubtedly represent several cases which will be included in one of these classes later on.

Table IV and Chart III indicate the status, at the end of the year, of the cases handled.

CHART IV

The most gratifying part of the work under the new organization is its concentration on the younger age groups where preventive work is most effectual.

Only 2.9 per cent of the cases were lost through lack of cooperation, while 59.6 per cent remain under care. In no previous year has as great a percentage of the total number of cases handled remained under care at the end of the year, the 1917 percentage for the League being, 54.9 and its high record in 1916 reaching 55.9 per cent.¹

Disposition of Cases

Losses due to no fault of the Unit, including moved and not found, constitute 58.3 per cent of the total lost, and 14.3 per cent of the total lost died. Diagnosed negative and dismissed account for 20.2 per cent of those not carried over. But 1 of the original 29 cases has been dropped through lack of cooperation, 1 was diagnosed negative and dismissed, 4 moved and 2 died, leaving 21 or 72.41 per cent still under care.

Perhaps the most gratifying results are to be

found in the study of age-groups reached. A glance at Chart IV will reveal that an enormous increase has been made in reaching the younger element, from 5 to 14 years of age in particular. In the light of modern belief that tuberculosis infection takes place largely in childhood, it would seem that the Unit is reaching just the groups with which the greatest preventive work can be done. And after all, the preventive work, although the least measurable from the point of view of clinical results except over long periods of time, is the most important and productive work to be done. This chart speaks for itself and needs no explanation. The Unit work has been compared with the most favorable year of the work of the League as far as reaching low age-groups, is concerned, which leaves no room for doubt as to the vastly greater amount of work done by the Unit.

Financial Side of Coordination

In terms of cost, has the League been repaid for its contribution of one nurse to the Unit? Excluding entirely the Mohawk-Brighton District, each League nurse averaged, in 1917, 1,438 visits at a cost, including overhead and excluding time spent in the dispensary, of \$.93 per visit. In 1918, 1,399 visits were made at a cost of \$1 per visit, the increase being due to an increase in salaries and an increase in car-fare. The Unit made 1,570 visits at a cost of \$502 per visit of \$.331, if the time of the block-workers in developing coop-

eration with the nursing service, be considered. Thus a greater number of visits has been made in the Unit than by each League nurse, at more than 45 per cent less cost per visit.

Each nurse cost the League an average of \$1,399 in 1918. Based on visits, the Unit has done 1,570 1,399 X \$1,399 or \$1,570 worth of work on the League basis of cost for 1918.

The League paid the salary of the nurse sent to the Unit which, together with the cost of part of a stenographer's time and of filing, amounted to \$983. For \$983 the League has had made for it more visits under the Unit Plan of organization than the average number made by League nurses at a cost of \$1,399.

On the basis of actual cost to the Unit: tuberculosis visiting has been done for \$793.89 or

¹ Of 3,172 cases handled in the entire city by the Anti-Tuberculosis League in 1918, 45.5 per cent were carried into 1919.

\$837.91 if the work of the block-workers is to be included.

The League nurse made 171 visits in the district in 1917. On the basis of 1,438 visits per nurse, this represents 12 per cent of the time of one nurse. Five Unit nurses made 1,570 tuberculosis visits in a year's time of a total of 19,286 generalized nursing visits.² Thus, visits were increased 918 per cent under the Unit Plan with an increase in time expenditure of less than 325 per cent.

Conclusions

(1) In the Social Unit, as acknowledged by all who have studied its work, a neighborhood organization has been built up which has led to an unprecedented neighborhood interest and cooperation.

(2) Not only the Anti-Tuberculosis League, but other city agencies, notably the Associated Charities, the Better Housing League, and the Humane Society have found the neighborhood organization very effective in their work in the District.

(3) In the field of tuberculosis, the Unit Organization has succeeded, through its intensified service, coupled with the unusual neighborhood cooperation, in increasing total cases handled 373 per cent, new cases 616 per cent, and cases carried over, 552 per cent. It still carried 60 per cent of its total cases at the end of the year. It increased the group in which preventive work can be done by 575 per cent. Only 2.9 per cent of its cases were lost through lack of cooperation; and from the point of view of age-groups reached, all data is undeniably in favor of the Unit plan of organization, and all at a cost of nearly 50 per cent less!

A New Measure of Efficiency

While no charge of inefficiency can be made against the League on the basis of its present form of organization, for the nurses are already seriously overburdened with work, it is evident that an improvement well worth consideration has resulted in operation under the Unit Plan.

Slowly, it is true, but surely, nevertheless, the interest and cooperation of the individual citizen is being sought and gained in the solution of problems of public welfare. And just as surely as those problems vary with the nature of the community, even to as small a unit as a city neighborhood, is their solution to be found only in the interest of the citizens of the neighborhood in them and their acceptance of responsibility for them.

². An actual analysis of tuberculosis and generalized nursing visits, just completed, show the average length of the tuberculosis visit to be slightly less than the generalized visit. Thus the actual increase in time has been somewhat less than 325 per cent.

WAR RISK BUREAU AND RED CROSS WORK TOGETHER

The American Red Cross was officially designated as the clearance medium for all community problems of service men at a recent conference of the several national welfare agencies with the director of the Bureau.

WOMEN PHYSICIANS IN SIX WEEKS' INTERNATIONAL CONFERENCE

A six weeks' conference of women physicians from nine countries opened in New York City during the third week of September. India, South America, Canada, Switzerland, Norway, Sweden, France, Italy, England and China will be represented. The gathering is being conducted under the auspices of the Young Women's Christian Association. The social morality committee of the war work council of the Association.

A tentative program for the conference has been prepared. "The Woman Physician and the Health of Women" will be the general topic under which such subjects will be discussed, as "Can Women Be Well Under Modern Living Conditions?", "Physical Examination as a Means of Health Education" and "Reconstruction of the Lives of Women in Relation to Health."

A study of special problems relating to the health of women will include the arguments for and against working women as mothers. Child hygiene and direction of the development of the child also have a place in the program. "Industrial Health" is a subject of interest to interest the business woman.

"Present Social Conditions and Their Effect on Health and Personality" will take up "The Marriage of To-morrow," "The Evolution of Love in Marriage" and "Marriage and Divorce." These discussions will take place in closed meetings for physicians only.

New York Association for Medical Education

The Association for Medical Education organized by physicians and surgeons of New York City, has been incorporated and is about to become active. It is felt that the many advantages offered for special study and research in the institutions of the city should be of greater service to humanity by broadening their field. The corporation consists of three hundred active practitioners and teachers. The officers are: Wendell C. Phillips, M.D., specialist in otology, laryngology, and rhinology, president; George D. Stewart, M.D., professor of surgery, first vice-president; Glentworth R. Butler, M.D., second vice-president; Haven Emerson, M.D., secretary; and Arthur F. Chase, treasurer. The executive secretary is Dr. Henry O. Reik, of Baltimore, recently lieutenant-colonel in the Medical Corps of the U. S. Army, commanding officer of Base Hospital No. 67, A. E. F. He was formerly associate in ophthalmology and otology (1909-12) Johns Hopkins University Medical School. Funds are in hand to maintain a Bureau of Information and Correspondence at the New York Academy of Medicine, 17 West Forty-third Street. Here data concerning all available facilities will be at hand. The work of the association will supplement the Bureau of Clinical Information and Society for the Advancement of Clinical Study. An effort will be made to standardize the instruction of the various medical schools of the city. A central residence for visiting physicians will be maintained where they may be kept in touch with medical matters. The association will cooperate with similar organizations abroad. A board of trustees will manage the business affairs.

BY JULES SCHEVITZ, GENERAL SECRETARY, OKLAHOMA TUBERCULOSIS ASSOCIATION, OKLAHOMA CITY, OKLA.

I—INDUSTRIAL COMMUNITY FOR ARRESTED CASES OF TUBERCULOSIS

“THE evidence is overwhelming that the campaign against tuberculosis has not yet developed adequate plans and facilities for the post-sanatorium treatment of patients,” states Dr. H. A. Pattison in the introduction of a report on “The Agricultural and Industrial Community for Arrested Cases of Tuberculosis and Their Families,” submitted to the Federal Board for Vocational Education.

The environment of the sanatorium graduate and his method of spending his time after working hours are frequently factors in determining the reactivation of the disease more important than the work itself. If the arrested case could work and mingle with men in like condition it is likely that his daily routine would be much more favorable for a permanent arrest of the disease. To provide a means for ex-patients to continue guarding their health, the establishment of agricultural and industrial colonies are recommended.

It has been realized that the agricultural colony alone will not be sufficient, because the urban dweller has little inclination to till the soil. Work in factories as well as clerical positions has been found to be compatible with the health of the arrested case so that diversified occupations must be available. The trend of opinion is directed toward the combined industrial and agricultural communities.

The main proposition offered by Doctor Pattison is the “development of industries around a community for the sake of that community, which is to be made up chiefly of arrested cases of tuberculosis among soldiers, sailors, and civilians.” Soldiers disabled for causes other than tuberculosis would not be debarred; but the totally disabled, epileptic, or mentally deranged, could not

be received. There would also be perfectly well people occupying executive positions or places in jobs such as were required to keep the processes going.

The community should be complete within itself, yet in immediate touch with neighboring villages and cities. The tract should be located within one hundred or two hundred miles of some large city, and not in an isolated corner of a far western state. The village proper should be laid out according to modern ideas of town planning to care for five hundred or one thousand population at the outset, with possibilities for expansion to 4,000. The department of health should be model in every respect, and the conservation and restoration of health would be given first consideration in the community. There would be diagnostic, pathological, and research laboratories. Every person who came to take up residence would be given a complete physical examination, including stereoscopic chest plates and biologic tests. Periodic re-examinations would make it possible to greatly reduce the morbidity and mortality rates in comparison with other industrial towns of like size. The population would be drawn largely from the sanatoriums and dispensaries of neighboring states.

Schools of the open air type would be used by all children. Special training courses would prepare men and women to give occupational therapy and pre-vocational training in sanatoriums. Another educational feature would be special post-graduate courses for physicians similar to the Trudeau school.

The author is opposed to having a government agency inaugurate such a community because of possible changes in policy due to changes in political administration. The necessary funds should be sought among the agencies that have concerned themselves with the needs of war and reconstruc-

tion, and these funds placed in control of five trustees, men of large affairs and broad vision in business and the professions. They would be comparable to the commissioners in the commission-manager form of government.

II—PRACTICAL TRAINING FOR PUBLIC HEALTH NURSES

THE recent enormous increase in the demand for public health nurses by communities large and small is taxing the available facilities for training these workers. The result is that many communities are obliged to employ improperly trained nurses, or else do without them. The National Organization for Public Health Nursing has made an attempt to meet these demands by suggesting to training school heads that the curriculum of training schools be broadened to include a course in public health nursing. Many training schools are now affiliated with social service agencies and private nursing associations and provision has been made for the practical training of some of the students.

Another field for the practical training of public health nurses is suggested by Dr. Carl E. McCombs, of the New York Bureau of Municipal Research, in the August issue of *The Modern Hospital*. The close affiliation of the hospital training school with the municipal health service is urged by Doctor McCombs as a means of providing practical training for many nurses, and incidentally will raise the standard of the health department by making it possible for many departments to obtain service which they are now unable to provide. "If proper cooperation with training schools could be effected, municipal health departments should assume the responsibility of paying the nurses in training salaries at least equal to the stipend which they receive as pupil nurses in the hospital training schools. Furthermore, municipal health departments would gain in efficiency by the very fact of becoming teaching agencies. Just as the teaching hospitals are more efficient than non-teaching hospitals, so teaching health departments would be more efficient than non-teaching health departments."

There are certain difficulties in the way of effecting such an arrangement. First, there is the necessity of readjusting the training school curriculum so that all nurses in training can receive this practical training; and, second, there is a feeling entertained in some quarters that health departments in their desire to get their work done would exploit the nurses assigned to them. It is probable that both these disadvan-

tages can be overcome by careful planning and close supervision.

III—TUBERCULOSIS IN CALIFORNIA STATE PRISONS

A STUDY of the health situation in the California state prisons at San Quentin and Folsom, with special reference to the prevalence of tuberculosis, was made from an examination of the biennial reports of the various Boards of Prison Directors published since the establishment of the two prisons in 1851 and 1881, respectively. Dr. L. L. Stanley who presents the review in the August issue of the *Journal of the Outdoor Life* adds to this his personal experience in dealing with tuberculous prisoners as resident physician of San Quentin prison.

From the very early reports of the medical directors is gleaned the fact that large numbers of prisoners died of tuberculosis, probably due to the prison sanitary conditions and to the close confinement. In numerous reports mention is made that tuberculosis carries off the greatest number of all those who die from natural causes. Indians and Spaniards were found to be especially susceptible to tuberculosis. The report made in 1895 makes mention, however, that those who died from this cause contracted the disease prior to their admission to the prison.

In 1913 a modern open air tuberculosis hospital was built on the roof of the "Old Hospital" and library building at San Quentin and was equipped with electric lights, modern plumbing, shower baths, toilets, and lavatories.

By means of thorough medical examination of every man who came to the prison many cases of tuberculosis were discovered on entrance, and open air treatment was begun at once. Complete x-ray, laboratory, and clinical tests are made to aid in the diagnosis.

IV—VARIATION IN INFLUENZA OUTBREAKS

THE first of a series of statistical studies of the recent epidemic of influenza is reported by Prof. Raymond Pearl.¹ Because of the varying medical opinion as to the properly reportable terminal causes of death of persons dying after having had influenza, the death rates from all causes have been used in the study, rather than those specifically reported as due to influenza or pneumonia. The weekly mortality statistics for the autumn of 1918 were analyzed for thirty-nine large American cities. It is shown in the first

1. *Public Health Reports*, August 8, 1919.

instance that there was an extraordinary degree of variation among the cities in this group with respect to the relative degree of explosiveness of the outbreak of epidemic mortality. The purpose of the study was to determine principally what factors had a causal influence in determining this great variation.

An analysis by the method of multiple correlation appears to demonstrate that an important factor so far found in causing this wide variation in respect of the explosiveness of the outbreak was the magnitude of the normal death rates observed in the same communities, particularly the death rates from pulmonary tuberculosis, diseases of the heart, and of the kidneys.

V—THE MASSACHUSETTS PLAN

THE general plan of organization of the state of Massachusetts for the campaign against venereal disease is outlined by Major A. N. Thomson.² The state legislature appropriated \$30,000 for one year to maintain the venereal disease campaign and in addition \$36,000 became available under the Chamberlain-Kahn bill.

A special subdivision was organized within the Division of Communicable Diseases of the State Department of Health and Major Thomson became chief of this new subdivision of venereal disease control in June, 1918. "From the beginning," states Major Thomson, "it was felt that the primary work would have to be conducted along two main lines, educational and treatment. The whole program was looked upon as a publicity campaign with the object of reaching the largest number of persons in the shortest period of time, and with the expectation of building a foundation for education regarding venereal disease."

In accordance with this policy every available means for education and publicity was made use of. The army film, "Fit to Fight," was invaluable, not only in that it imparted much valuable information to those who viewed it, but also it produced considerable editorial comment in all the state newspapers on the general problem of venereal disease control. The lecture bureau, with the cooperation of the sections on men's and women's work, was successful in reaching many thousands of men and women. In line with the general work of education an early effort was made to reach the draftee prior to his going to camp. This was done under the auspices of the Adjutant General of the state in cooperation with the Committee of Public Safety.

Other measures employed are the maintenance of free diagnostic facilities, establishment of

free treatment facilities, compulsory reporting of venereal diseases, elimination of quacks and charlatans, restrictions to prevent treatment by drug clerks, and examination and treatment of prisoners.

VI—SANITARY PRIVY PROGRESS IN NORTH CAROLINA

THE North Carolina State Board of Health³ covers in a practical manner what A. J. Warren, assistant secretary of the Board, terms "the largest single factor that is impeding the progress of health work in North Carolina and that confronts her citizens today—the disposal of human excreta."

The last General Assembly passed an act requiring every home within three hundred yards of another home to have an improved type of privy that the State Board of Health would approve. By means of a series of short articles illustrated with numerous photographs and drawings the citizens of the state are informed of the advantages and disadvantages of different types of privies together with their comparative costs.

The subjects considered in the *Bulletin* are: The state-wide privy law explained; sanitary principles of the construction of privies; types of improved privies; plans and specifications for approved privies; summary of rules for maintenance of different types of privies; economics of privy construction and maintenance; and machinery and methods for enforcing the law.

It is claimed that this issue of the *Bulletin* presents the most complete study that has yet been made public relative to the practical application of the various standards and types of privies now in use.

VII—NUTRITION CLINICS AND CLASSES

A THOROUGH discussion of the functions of the nutrition clinic and the nutrition class was presented by Dr. William P. Emerson at the recent International Child Welfare Conference held in Washington and has since been reprinted.⁴

The object of the nutrition clinic is to identify that group of under-par children who are retarded in weight and height on account of malnourishment. The under-nourished child in school generally receives no treatment for his malnutrition because he is considered well. By means of physical, mental, and social examination it is possible to make a diagnosis of the cause

2. Social Hygiene, July, 1919.

3. Health Bulletin of the North Carolina State Board of Health, July, 1919.

4. *Bost. Med. & Surg. Jour.*, 1919, clxxxi, No. 5.

of malnutrition, thus leading to its proper treatment. The simple procedure of weighing and measuring each child will identify all but the border-line cases.

The physical examination reveals an average of more than five defects for each child. The mental examination is made in most instances during the course of the physical examination when it is determined whether there is any question of mental deficiency or retardation. The home life of the child is studied by a forty-eight-hour program which includes a list of food taken during that time, his hours of sleep, work, and play, and time spent in the open air. The following have been found to be causes of malnutrition: fast eating, insufficient food, the use of tea and coffee, late hours, closed windows at night, too little time in the open air, poor hygiene, overpressure and long hours in school.

To remove the physical and mental causes of malnutrition the cooperation of the child, physician, teacher, and parent is required. This cooperation is best obtained by means of nutrition classes of not more than twenty children in each. Charts showing the weekly weight of each child are kept. Diet lists showing the amount and kind of each article of the child's diet for two consecutive days of each week are examined by the nutrition worker. The twenty-four-hour amount should be large enough for gain, usually 2,000 or more calories. The child gaining most is given a gold star and placed at the head of the class. Usually the losing child one week is at the head of the class the following week. The doctor conducts the exercise and tells each child what he is to do the following week that he may gain. He praises the children who have gained, but it is his special duty to discover the causes for loss in those who have not gained. Parents occupy the back seats and listen to the suggestions made by the physician.

Where there is complete cooperation and the essentials of health can be wholly obtained, the child should reach his own normal standard of weight in ten or twelve weeks. From 5 per cent to 10 per cent of the children present serious medical problems requiring most careful study by the physician.

During the period of treatment the children should be placed in open air or open window class rooms. Special rest periods should be observed before and after noon. Mid-forenoon and afternoon lunches should contain about 250 calories of food. Children gain faster on less food taken in small amounts five times a day than when a larger amount of food is taken in three meals. By its appeal to the imagination of the child the

class method makes him do for himself what no one else can do for him.

VIII—THE MALNOURISHED CHILD

MUCH interest is being centered by health authorities all over the country on the question of the malnourished child. Recent studies indicate a surprising amount of malnutrition among children of school age, and efforts are being made by some school and health authorities to discover the causes of malnutrition and attempt to eliminate the causative factors. According to Dr. Josephine Baker, more than one-fifth of the school children of New York City are undernourished. The percentage for the entire United States is even higher. Dr. Thomas Wood places it at from 15 to 25 per cent. Since this takes no count of the malnourished children under school age between the ages of two and seven, when malnutrition usually has its beginning, from three to six million hungry American children is probably a conservative estimate.

The Children's Bureau publication, "What Is Malnutrition," prepared by Miss Lydia Roberts, contains a very timely description of some of the causes as well as suggestions for treatment. "Many of these children are going hungry," says Miss Roberts, "because their parents cannot afford to buy a sufficient amount of suitable, nourishing food. Thousands of American families are today living on an income which does not permit of an adequate diet. But poverty is not the sole cause of malnutrition. Many mothers do not know how to spend their money to get the best return in food value, or how to plan healthful, nourishing meals for their families. Many others have not sufficient control over their children to induce them to eat the right things, and to take the sleep, and rest necessary to development. . . . They take pride," Miss Roberts points out, "in having a 'delicate' child. They do not realize that the undernourished boy or girl is peculiarly susceptible to disease, that the listless, inactive, malnourished child, who is constantly tired, who leans against the school house while his comrades play, is father to the man who is handicapped because of low vitality and a poorly developed body—is the inefficient adult, the rejected army recruit."

The nutrition clinic and nutrition class are recommended as effective means for overcoming the present widespread, deplorable prevalence of malnutrition.

AMERICAN PUBLIC HEALTH ASSOCIATION MEETS AT NEW ORLEANS

More than one hundred and fifty papers, addresses, reports of committees, and discussions on as many phases of public health problems will be presented by speakers at the forty-seventh annual meeting of the American Public Health Association, to be held at New Orleans, La., October 27 to 30, 1919.

The first general session will be opened by the Governor of Louisiana and the Mayor of New Orleans. Their speeches of welcome will be followed by the presidential address of Lee K. Frankel. Sir Arthur Newsholme, head of the Local Government Board of Great Britain, will address the session on "Historical Development of Public Health Work in England."

The second general session will be devoted to a symposium on malaria. Those taking part in the discussion include several members of the United States Public Health Service and the International Health Board, among them Major General W. C. Gorgas, U. S. A., retired, director of yellow fever control, International Health Board, Panama; Wickliffe Rose, general director, International Health Board, New York City; and Dr. J. A. Ferrell, director for the United States, International Health Board, New York City.

The third general session is given to a symposium on influenza. Health officers from several cities and states will read papers and the reports of various committees will be presented.

At the fourth general session Dr. C. J. Hastings, medical officer of health, Toronto, Can., will read a paper on "Generalized Public Health Nursing in Toronto." The installation of new officers will take place at this session.

The sections which have arranged programs include the Section on Public Health Administration, the Laboratory Section, the Sociological Section, the Section on Industrial Hygiene, the Section on Vital Statistics, the Section on Food and Drugs, the Sanitary Engineering Section and the Section on Social Hygiene.

Correspondence concerning the various sections should be addressed to the program chairmen, as follows:

Section on Public Health Administration: William F. Cogswell, M.D., secretary and program chairman, Helena, Mont.

Laboratory Section: A. B. Wadsworth, M.D., vice-chairman and program chairman, 278 Yates Street, Albany, N. Y.

Sociological Section: Walter H. Brown, M.D., secretary and program chairman, 280 Glenwood Avenue, Bridgeport, Conn.

Section on Industrial Hygiene: A. J. Lanza, M.D., secretary and program chairman, 805 G Street, Washington, D. C.

Section on Vital Statistics: Richard Lappin, secretary and program chairman, Bureau of the Census, Washington, D. C.

Section on Food and Drugs: Harry W. Redfield, M.D., program chairman, Bureau of Chemistry, Washington, D. C.

Sanitary Engineering Section: Paul Hansen, program chairman, Illinois State Board of Health, Springfield, Ill.

Section on School Hygiene: Julius Levy, M.D., program chairman, Department of Health, Newark, N. J.

The program of the Section on Public Health Administration will be opened by a symposium on the topic "The Privy as a Public Health Problem," which will be the subject of a paper by L. L. Lumsden, Assistant Surgeon

General, United States Public Health Service. "Public Health Administration" is announced as the subject of a symposium under which several public health officers will offer papers and discussions. There will be a round table discussion of the question of appropriations for health work. The following topics will be considered: "How to Obtain Adequate Appropriations for Public Health"; "What Can We Do to Bring About Reasonable Compensation for Health Officers?"; "Experiences of Health Officials in Obtaining Appropriations."

The tentative program of the Section on Industrial Hygiene is as follows:

PROGRAM OF SECTION ON INDUSTRIAL HYGIENE OF AMERICAN PUBLIC HEALTH ASSOCIATION

Monday, October 27, 2:00 p. m.

Address of Chairman. Need and Method of Coördinating Federal, State and Local Health Agencies in Promoting Industrial Hygiene.

A Program for Organizing and Coördinating Industrial Clinics. T. GRIFF MILLER, M.D., University of Pennsylvania, Philadelphia, Pa., Utilizing the Out-Patient Department for Industrial Clinic Work. WADE WRIGHT, Massachusetts General Hospital, Boston, Mass.

Utilizing Records of Plant Medical and Surgical Departments for Furthering Plant Hygiene. BERNARD J. NEWMAN.

Placement and Replacement of Employees on the Basis of Physical Examinations. HARRY MOCK, M.D., Chicago.

Classifying Employees and Increasing Production by Improving Their Physical Condition. WM. J. CURRY, M.D., Holyoke, Mass.

Tuesday, October 28, 9:00 a. m.

Fundamental Factors in Plant Hygiene. DON LOWE, M.D., Akron, Ohio. Health Hazards of Non-Poisonous Dusts. EMERY R. HAYHURST, M.D., University of Ohio, Columbus, Ohio.

Health Hazards of the Dye Industry. C. E. FORD, M.D., New York, N. Y.

Systematic and Dermatic Effects from the Use of Cutting Oils and Compounds. H. D. PEASE, M.D., Lederle Laboratories, New York, N. Y.

Industrial Fatigue: Present Status of Investigations. FREDERIC S. LEE, M.D., New York, N. Y.

Wednesday, October 29, 9:00 a. m.

Special Health Hazards of Women Industrial Workers. LILLIAN ERSKINE.

The Insurance Company and Industrial Hygiene. AUSTIN D. REILEY, New York.

The Industrial Physician and Welfare Work. W. IRVING CLARK, M.D., Worcester, Mass.

The Part Played by Community Insanitation in the Incidence of Industrial Diseases. ROGER PERKINS, Cleveland, Ohio.

Legislative Standards in the Field of Industrial Hygiene.

The Laboratory Section announces a list of thirteen scientific papers. The tentative program of the Sociological Section includes symposiums under the following subjects. "The Relations of Living Conditions to Health"; "The Influence of Industrial Relations Upon Health"; "Symposium on Community Medicine."

The reports of various committees on institutional, hospital, and health department statistics and registration will be presented in the Section on Vital Statistics. The recent studies of some of the large insurance companies will be described and reviews of influenza mortality statistics will be given.

The Section on Food and Drugs includes in its program several papers discussing the problem of drug addiction in the light of current activities in this field of public health work. Another subject of current general interest which this section will discuss is the matter of meat inspection and cold storage systems.

The full program of the conference will be printed in the October issue of the *American Journal of Public Health*.

The *Survey* for September 6, 1919, gives a first hand view of the results of the war upon the physique of the German people from the personal observations of Miss Jane Addams and Dr. Alice Hamilton, who recently spent some time in Germany in connection with the English and American Society of Friends. The report presents the unhappy condition of women and children, particularly, as a result of the hardships of war.

PROBLEMS IN SOCIAL MEDICINE

Medical and Health Education, Child Welfare, Social Insurance, Rehabilitation, Medical Law and Allied Subjects

JOHN A. LAPP, LL.D., Editor

THE HOSPITAL SOCIAL SERVICE QUARTERLY

THE publication of the *Hospital Social Service Quarterly* which began in February of this year adds a new and quite indispensable journal for physicians, nurses, and hospital workers. It is the organ of the Hospital Social Service Association of New York, and will be the clearing-house for the newly organized Association of Hospital Workers.

There is perhaps no field that involves a wider range of activities of constructive tendency than that of the hospital social service worker. Serving as an intermediary between the physician, the dispensary, the hospital, and the home, it becomes the function of this service to search out and make right the hygienic conditions of the home, and to put into operation such practices on the part of the patient and his family as will make effectual and permanent the results of medical service and hospital care. It is gratifying to learn that this body of highly trained workers now has a channel for the discussion of their problems, and for collected reports of the important data they gather.

We reproduce here the announcement of the *Quarterly* in the form of an editorial by Michael M. Davis, Jr., one of the contributing editors:

"Twelve years ago, Hospital Social Service, an infant amid the growing family of new public health movements, needed justification for being born. To-day, Hospital Social Service is recognized by all first rank medical institutions in this country. The movement has become prevalent and even fashionable, so that one of the chief dangers is that its form may be too widely copied without its spirit and substance.

A new organ for this movement, super-added to the thousands of existing periodicals, may require justification. The number of hospital social

workers is increasing. The social problems and technique through which they wrestle, the ideals towards which they strive, are many and various, and seem to need some mouthpiece of their own making. The first stage of any movement is of the pioneers. During that period a reason for being must be established. Hospital Social Service has passed successfully through that period. The second stage is that of formulation of principles and of methods of practical application. Through that stage we are now passing. For the successful formulation, dissemination, and practical application of principles and methods, in many and many hospitals and dispensaries of this country, Hospital Social Service needs a national organ, which we hope this will be.

"We want the *Quarterly* to be useful to the members of social service departments, to their staff physicians, superintendents, and trustees. We want it to be a forum for the expression and exchange of opinions, for telling about things that have been done, and other things that are planned or dreamed. We hope that the *Quarterly* will be of practical aid in the routine of daily duties; we trust that it may now and then show the way to some sunny heights of inspiration. The war has brought forth the spirit of service in wonderful outpouring. The ending of the war will divert many streams of that spirit into channels of peace, and turn into various forms of social service personalities who, unknown to us and often to themselves, were waiting for the opportunity which the war gave them to blossom into usefulness and power. Hospital social service cries out for more workers. It has much to offer to such personalities. We hope that the *Quarterly* will not only aid those already enlisted under the banner of hospital social service, but will also help to rally and to train the recruits and the captains of the future."

EDITOR.

THE PHYSICIAN AND HUMAN CONSERVATION

BY JAMES H. McBRIDE, M.D., PRESIDENT, AMERICAN NEUROLOGICAL ASSOCIATION, PASADENA, CALIFORNIA*

ON this occasion, when you might expect me to speak in the line of the specialty, the subject of human conservation may seem rather remote. It has none of the interest of novelty and has no problems for the laboratory except that oldest of laboratories in which the problems of life are being solved. The subject is familiar, but life is made of familiar things of which we find it necessary frequently to remind ourselves, and experience teaches that it is much more profitable to be reminded than to be instructed.

The existence of so much disease that is preventable, the increasing amount of insanity, feeble-mindedness, and imbecility that are usually evidence of individual and family degeneracy, the poor showing of our young men in our recent war conscription, and other conditions of bad import too numerous to be recounted, have led me to consider at this time the subject of disease prevention and human conservation. This can only be a suggestion, as there is no time to frame an argument; it can only be a hint of the facts, not a presentation of them.

My subject is not so remote from our specialty as it may seem, for we are interested in disease and its prevention, and conservation deals with both. The great merit of prevention is that it begins at the source, and that is the place to stop trouble. To bring a dying man back to life and health is more attractive and picturesque than the homely process of preventing him from being sick. Just a plain healthy man may be useful, but he is not necessarily interesting. Society, however, prefers that a man should first be healthy.

We have wasted a vast amount of human material in the past through mere neglect; and we have wasted as much more through being satisfied to care for the wreckage, without considering how to stop the supply. The result has been that while we have been building hospitals and asylums, disease has been increasing with the

THE SPAN OF LIFE CUT SHORT

Physical education is the only real education. Bad mental training and neglect of the body spell retardation, mental stagnation, physical disability, and incompetence. Health is achieved by active effort. The physician's best service is in working out the right regimen for his patient.

To be lively at seventy or an octogenarian at forty is largely a matter of choice.

Let scientists come forth from their laboratories and tell us how to live. The curative arts and specialties are but a partial service, and are a poor substitute to offer in place of preventive work.

vation. Resolutions meaning presidential addresses, unassisted by organized effort, will probably get no farther than to illustrate the infant death rate of good intentions.

The physician witnesses the growth and the unmaking of men in a way that others do not. He sees that simple, wholesome living produces healthy and effective lives. He sees untrained and, therefore, incompetent men and women struggling in a bad environment, becoming prematurely old-octogenarians at forty. He sees children who are underfed and dwarfed in mind and body repeating later in their own incompetence the incompetent lives of their parent.

We doctors have in the main been carrying on an ambulance service in the past; that is, we have been picking up the injured. It has been a great work, unequaled by any other human agency. It has, however, been a partial service, in that it has dealt mainly with results and has achieved relatively little in the way of prevention. This was unavoidable as it has been only within the past few decades that our knowledge of the obscure sources of many diseases and degeneracies has permitted the formulation of a general plan for health conservation that would accomplish such results as are today possible.

A conservation plan should be much more than one to prevent contagious diseases, or even to prevent all disease. It should be a plan for human reconstruction in the broadest sense, not

growth of population, so that the age-old "pestilence that walketh in darkness," in the form of devitalizing conditions, has been breeding disease and degeneracy and pouring its victims through the gates of charity.

There is much unused power in the medical profession in this country, some of which might surely be devoted to educating the public to understand the importance of human conser-

of societies and well

addresses, unassisted by

the infant death rate of good

intentions.

The physician witnesses the growth and the unmaking of men in a way that others do not. He sees that simple, wholesome living produces healthy and effective lives. He sees untrained and, therefore, incompetent men and women struggling in a bad environment, becoming prematurely old-octogenarians at forty. He sees children who are underfed and dwarfed in mind and body repeating later in their own incompetence the incompetent lives of their parent.

We doctors have in the main been carrying on an ambulance service in the past; that is, we have been picking up the injured. It has been a great work, unequaled by any other human agency. It has, however, been a partial service, in that it has dealt mainly with results and has achieved relatively little in the way of prevention. This was unavoidable as it has been only within the past few decades that our knowledge of the obscure sources of many diseases and degeneracies has permitted the formulation of a general plan for health conservation that would accomplish such results as are today possible.

A conservation plan should be much more than one to prevent contagious diseases, or even to prevent all disease. It should be a plan for human reconstruction in the broadest sense, not

*Presidential address before the American Neurological Association, Atlantic City, N. J., June 17-18, 1919.

alone for cripples, or for defectives, but for rebuilding the bodies of all the people, beginning with childhood and not necessarily ending with completed growth. Such a plan should be administered by the government. The business of the profession will be to secure the adoption of a plan. It will require the united efforts of physicians acting in every community to educate the people and show them what human conservation means. Unless the general public can be convinced of the necessity for it, the government will be slow to put a constructive program in force.

The large number of our young men who could not pass the examination for the army during the recent war furnished convincing evidence that there is in this country a great deal of poor physical development. It is, too, quite possible that some defects were overlooked but certainly enough were exposed to show the physical vigor of Americans is not what it might be or what it ought to be. The fact that so much degeneracy was shown to exist in persons of the ages of those examined would indicate that there are others older and others younger who are equally at fault physically. The humiliating revelations of these army examinations are an admonition to the country to see that the boys and girls of our day have the training that will enable them to meet successfully the tests of active life.

There is fortunately a growing interest in the medical profession in preventive measures which is reflected in activities of various states and in that of the general government. The health work in cities, the community nursing, the follow-up work of dispensaries and hospitals, the new interest in housing—one of the biggest problems—these and many other activities are educating the public for the comprehensive program that will some day come.

National Health Plan

We have also in recent years been moving toward a national health plan in the activities of the marine hospital service, the work of the Surgeon General's office, and the annual health lectures provided by the American Medical Association. The next step should be a comprehensive plan for the entire country. It is not possible nor necessary to suggest a scheme here, but if the profession could induce Congress to appoint a medical commission to investigate the need for a health program, such a body could easily produce evidence of the necessity for it and secure action.

There is no finer chapter in medical history, nor one that is more significant, than that which records the first achievements in prevention of

disease. When the genius of a country doctor connected the milk-maid with the cow, and devised prevention by vaccination, he took the first step toward doubling the usefulness of our profession by showing that some diseases may be prevented. What Jenner demonstrated was not only a matter of science but a social fact of great importance. The prevention of disease earlier received an impetus from the old Venetians when they put the word quarantine in the dictionary. They might have waited until the plague had developed in the city and then have administered their remedies; they preferred prevention.

Social Loss From Disease

Eleven thousand young men applied for the Naval Reserve in 1913 and only 316 were found physically fit. It has been said that these tests are severe. They are. Should the United States lower its standard to fit our degenerate youth or should we raise the physical level of our manhood? These tests are probably not higher than those any normal young man should be able to pass.

The annual social loss from disease is equal to the destruction of a great war. This is all the more regrettable, because most of it is preventable. It is a serious thing that there are more than 500,000 deaths from preventable diseases in this country every year, 400 times the number that were lost on the Titanic, a tragedy that shocked the world. Three hundred thousand babies die before they are a year old, a loss of which the figures are a poor measure. More people die before the fiftieth year in the United States now than in the time of our grandfathers, though in several European countries more people live beyond the fiftieth year than was the case two generations ago.

Ripley says that of 100 Jewish babies born in Massachusetts, fifty will be alive at the end of seventy years. Of 100 babies other than Jews born in Massachusetts, fifty will be dead in forty-seven years. Why is there this difference of twenty-three years under essentially the same environment? Is it due to a more intelligent care of health and a better scheme of life?

There are said by school authorities to be 500,000 feeble-minded children in the public schools of this country, and it is probable that there are several times that number in the adult population. These morons breed true to the laws of degeneracy in families of ten and fifteen children. Where will this country find room for the 2,000,000 or 3,000,000 degenerates of this class that we will have two generations from this time? Has this Association ever called public attention

to the danger that the feeble-minded may pollute the healthy blood of this nation?

Man seems to be the hardest of all animals to kill. Human beings will survive mistreatment that would kill pigs and cows. If a man kills another with an ax or a pistol, he is punished; if he should kill a man with a slum house, he is not punished, though the men who rent slum houses are so much more dangerous than men with axes and pistols are relatively harmless creatures. The owners of slum houses help to fill our hospitals with sick and insane, and in addition they furnish a large supply of degenerates who prey on society. A general plan of health conservation should remedy these and other like conditions that cause much of the disease we see in public hospitals and much of the degeneracy that we meet outside of them. These cases of disease are the natural drift from such sources as bad housing and its many attendant evils that are spreading like an epidemic not only in cities, but on farms and in villages. Such insanitary homes with their inadequate care of children are the causes of much stunted growth, incompetence and disease. Here, also, only a comprehensive program of health conservation can correct these evils.

No discussion of this subject could properly omit mention of our educational system: while the Government plan of health conservation could not be made to apply to education in the states, it could by suggestion and advice make health conservation in all the states the first consideration in education. Indirectly, therefore, a government plan would determine that the states did their duty.

Health Conservation in Public Schools

If we are to prevent physical degeneracy, or rather if we are to stop that which is now going on, we must begin with the children in the public schools. Their health should not only be guarded, but the training of their bodies is quite as important as the training of their minds. This should appeal to the intelligence and public spirit and the essential loyalty of every physician, less, however, as a medical practitioner, than as a man who understands or ought to understand the importance of medical sociology. Every man and woman who walks the streets today is essentially a product, physically and mentally, of our schools. Has our educational system been a success—if not, why not?

The power and much of the genius of a nation depends on the health of its citizens, and the human preparation for effective living and national achievement should be made chiefly

during the growing period. These little folks who are the raw material of our future citizenship are naturally outdoor animals. Their mental activity is founded on physical activity. Our schools will never be organized on the proper basis until we recognize and put in practice the fundamental principle that physical training should be the foundation of mental training.

Every medical man should have an immediate interest in existing methods of education, especially in the conditions under which those methods are applied; and of all physicians the specialist in nervous and mental diseases should have the greatest interest. Any one of the younger specialists of this Association could go into any public or private school today and select with an approximation to accuracy a pretty large group of pupils who will probably be his patients or his contemporaries' patients fifteen or twenty years from this time. He will need to interpret the significance of the nervous attitudes of the children, the instability of nerve centers shown in the facial expression and in the general irregular muscular movements, and other familiar signs of imperfect development. One sees in these cases the results of half starved nerve centers and neglected muscular activities, struggling in vain for normal expression in a turmoil of wasteful effort.

Hundreds of thousands of young people are yearly going out into the world unprepared for life because their only training in school, if training it may be called, has been a system based on word symbols. There is little or no discipline for young people in the unrealities of books; they cannot connect them with life, for to them life is in doing. The failure that so many of them experience in after years is also due, in large degree, to a lack of proper physical development. From the bad mental training and the neglect of the body there results much retardation, mental stagnation, and physical disability, which make incompetents of many and invalids of others, while a few, through the miracles that nature daily performs, get into the small class of successful people.

The commission appointed by the National Educational Association says in a recent report that it would focus secondary education on the great social objectives, and it places the health of the young at the head of the list. This is encouraging, for our teachers as a class have been slow to recognize, if indeed they do recognize, the important fact that health and sanity and success in life depend more on good physical development than on all the book knowledge that has been or can be packed into the healthily rebellious minds

of the young. It is true that manual training and kindred instruction are given in certain schools, but have not reached the great mass of boys and girls of this country.

It is a fundamental fact in human development that young people have a positive hunger for doing things, for learning as the race learned, to *think by doing*. The greatest discovery man has made to date was the first tool he fashioned. It was the chief means of the early development of the race, and so deeply is this primitive talent planted in the brain that very psychiatrist knows that the ability to do things is one of the last faculties lost. In teaching the young how to use the hands, the teacher is leading them over the long way the race came; the teacher helps them to short-circuit the race process. In this way even a dull boy can be taught to do some one thing well, and such training will save many from the failure that has condemned thousands to insanity, crime, or pauperism.

Any physician who has seen much of the insane in public institutions must have been impressed with the large number of this class whose mental disorder, where the basic cause could be explained, has been chiefly due to the fact that they had never learned to do any one thing well. The dullards and incompetents that come from our public schools would, if they could speak, tell a tragic story of the failure of the educational side of our social system.

Medical Profession and Health Conservation

It is an important truth that nothing stands alone in this world, not even a medical association. We go up or down together. We are here today not solely because we are physicians, but also for the reason that society created us as a profession because it needed us, and we are therefore always serving its purpose. Our most private work is really a social and public work, so that in all we do we are going on the errands of society. Each one of us is an essential part of this moving human order that keeps society together and holds humanity to its sober tasks.

The world is passing into a new era. Though wars cease and the harsher strifes of men may disappear, the old struggle will go on under other forms which in the long run will be quite as destructive. Again the final test is the individual test, for in the last analysis the reserve power of a nation rests on the ability of men and women to endure stress.

We cannot say that race decay has not already begun among the people of this country. There is much evidence that it has begun. No race nor nation, not even our own, can ever be free from

the conditions that produce degeneracy. These are inherent in every form of human organization. They are all the more dangerous for being subtle and obscure in operation. They may act through generations lowering the resistances of individuals and families, and in widening circles a nation becomes involved.

Every medical association and every society should do systematic educational work with the public in the interest of a human conservation program. Medical men should not be willing to leave to others the credit or the task of leading this movement, which is specifically a social duty of physicians. The profession owes it to society and to its own character as a scientific and progressive body to demand that the health and physical vigor of the men and women of the nation be cared for by the nation, and raised to the highest standard. For this, or any association of specialists, to take official notice of this subject, I realize would be a departure from custom. Departures from custom, new activities, are generally highly beneficial. They furnish stimulating experiences and a new form of spiritual exercise that is needed by the best of men and even by associations. They take the individual into bracing altitudes; they have been tonics to the social body in many an invalid period. All advance has been due to departures, that is, to new views, and new ideals that in all ages have set men's thoughts in higher and better ways. It has been such departures that have roused the inquiring, pioneering spirit that has led to great discoveries and kept men moving toward new horizons.

In this period of industrial and social reconstruction, when all interests are becoming intertwined, when human interspaces grow smaller, and new relations create problems that change our views of life and society, it is necessary that the medical profession also make certain readjustments, that it annex human interests to its older activities, if its members are to maintain its fine traditions and keep step with social progress.

All professional life is beset by the danger of a certain bias which habits of work in any special line tend to create. We humans are made of malleable material and we are likely to be moulded to a rather definite shape by our occupation all the more likely because the process is unconscious. It is not easy to resist the common tendency to become set in certain habits and ways of thinking, with the result of lessening of general interests, a limiting of intellectual curiosity and growth, which cause many men to atrophy on some of the best sides of character.

Society needs now, and needs more than ever before, men who answer to that severest test of character—the ability to grow. Not the linear growth that is in the direct way of men's daily work and which is a relatively easy process; men are needed who are capable of lateral growth, who recognize the new human border-land of interests that increasingly demand attention. It needs men who take the social view of their work,

who understand the individual and social value of life and see the importance of increasing that value. The people of this country do not appreciate the need of human conservation; they have not been told as only doctors could tell them that it is necessary and urgent. Shall we wait and allow society finally to lead, or shall we take the wider view of our mission, and become the pioneers of a great constructive movement?

CONVALESCENT CARE

BY MAURICE B. HEXTOR, EXECUTIVE DIRECTOR, FEDERATED JEWISH CHARITIES, BOSTON, MASS.*

AS FAR as the writer knows this is the first time the National Conference of Jewish Charities has considered the subject of convalescent care. The lack of discussion of the subject and the paucity of facts which we have been able to secure by correspondence is a true reflection of the degree to which organized effort has failed to provide systematic care for the convalescent. While after-care for the tuber-

culous patients has been discussed for a number of years, convalescence as an all embracing topic has received scant attention. Indeed, the chairman of this section on health expressed surprise at the existence of the Convalescent Home in Cincinnati as an integral part of the health service of the United Jewish Charities.

It is true that most of the larger charities provide convalescent care in certain selected cases. In a more or less desultory fashion most organizations provide country rest after severe illness. However, unless the community has provided facilities for convalescent care for twelve months of the year through a well-defined bureau or through an institution, it cannot be said that such a community recognizes the importance of convalescent care as an aid to rehabilitation. The presence of such an institution or bureau focusses upon this particular sphere of activity the attention of those who support the institution, and induces continuous requests for this care by that part of the community for whom the institution

This is the story of how little children in ill health and adult convalescents are guided and helped along the up-hill road to complete recovery. It had been the custom of the United Jewish Charities to send children to the country for a vacation in the effort to overcome malnutrition, anemia, and cognate conditions. The necessarily brief stay accomplished practically nothing. Three years ago those in authority ventured upon the policy of sending such children to a convalescent home for three or four months. While there they attend school. The experience thus far gained attests to the practical utility of the Convalescent Home.

has been established. Doctor Moss, chairman of this section, writes that from the inquiries he recently sent to 110 cities he found but two communities which have convalescent homes. This is an understatement of service of this kind. It will be interesting to scan the field of convalescent care as at present covered by Jewish endeavor.

We have found seven homes for convalescents in five cities which are,

in the order of their establishment, as follows: (1) The Solomon and Betty Loeb Home for Convalescents, New York City; (2) the Jewish Convalescent Home, Cincinnati; (3) Mirium Convalescent Home, St. Louis; (4) Rest Haven for Women and Girls, and (5) Rest Cottage for Men and Boys, Chicago; and (6) the Frauen Verein Convalescent Home, Boston.

The Solomon and Betty Loeb Memorial Home for Convalescents in New York City, was founded in 1904 and was opened for the reception of patients in July, 1906. It lies within convenient reach of New York City.

The Home possesses about seventy acres of ground on which have been erected a central administration building; three cottages, one each for men, women, and children; and a fifth residential cottage is held in reserve for special emergencies. The present total capacity of the Home averages one hundred beds, and it is kept open throughout the year. Patients more than fourteen years of age who are able are expected to pay \$5 per week; those between the ages of five and fourteen, \$3 per week.

*Read before the National Conference of Jewish Charities, Atlantic City, N. J., May 30, 1919.

When the committee on admissions is satisfied that a patient is unable to pay such a sum, the charge is remitted in whole or in part. The railroad fare, however, must be paid by the patient. Applications accompanied by a medical certificate are received either from those recently discharged from hospitals, or from persons who are treated by private physicians. In all cases, however, candidates must be examined by the admitting physicians of the Home. These examinations are conducted in the United Hebrew Charities Building in New York City.

The Home does not accept pulmonary consumptives, persons still suffering from acute infections, or afflicted with contagious infections or loathsome diseases, or those suffering from hysteria, epilepsy, or advanced nervous disorders. Children under five years are not admitted except when accompanying sick mothers and by special permission of the Board. The institution is non-sectarian.

There is a well defined program of after care for the patient leaving the Home. The discharged patients have been organized into an alumni association, and hold regular meetings. Since 1915 male applicants have been referred to a different convalescent home nearby, thus reserving the home for little children, girls, boys up to the age of sixteen, and women; the result is a quieter atmosphere much more conducive to convalescence. Although the Home is open to patients treated by private physicians, most of such applicants are refused. During 1915, the last year for which we could secure a report, of the 1,963 patients referred by private physicians only 105 were admitted.

Jewish Convalescent Home, Cincinnati

The second convalescent home to be established was the Jewish Convalescent Home in Cincinnati which opened its doors in the summer of 1913. For almost ten years previous to that time the United Jewish Charities, of which the Convalescent Home is an integral part, had been sending patients in selected cases to country homes for a convalescent period. It was found, however, that this method did not bring maximum results: difficulties in finding homes, proper supervision of diet and rest, and proper medical supervision are among the difficulties. The Home in Cincinnati has a capacity of seventy patients and is situated in the suburbs on the hill-tops. The same restrictions are made as to causes for which patients are admitted as in the Loeb Home in New York. All applicants come through the health department of the United Jewish Charities, and only patients of means and those re-

ferred by private physicians are excluded. When originally opened, the stay of patients was limited to only two weeks with a single possible extension of two weeks. It was soon found that this duration of stay was not sufficient and, al-

To this Home are sent children from the public schools who are found to be suffering from malnutrition, anemia, and cognate conditions. They remain at the Home until their physical condition approximates normal. While there they attend public school.

though the rule has never been abrogated it is honored in its breach. For several years the Home was not utilized to its full capacity during the months from October until May, and efforts were therefore made to keep the institution full.

Through the department of school hygiene were found a large number of children suffering from malnutrition, anemia, and cognate conditions. It had been custom of the United Jewish Charities to send children to the country for a summer vacation period, but it was found by follow-up and

Number showing loss in weight.....				98	

We have developed norms for Jewish children from two sources: (1) by interpolation from the anthropometric measurements made by Professor Boaz for the United States Immigration Commission (Volume 38); (2) through standards obtained by examining an unselected group of about 1,000 Jewish children in the spring of 1918.

The Convalescent Home has been also used quite extensively for children sent to the hospital for the purpose of having their tonsils and adenoids removed. These children are transferred directly from the hospital to the Convalescent Home. The admitting physician of the Convalescent Home is located at the Wilhelm and Gette Beckman Dispensary operated by the Jewish Charities. He is likewise the physician at the Home so that continuity of supervision is secured.

Other Convalescent Homes

The Mirium Convalescent Home was established in St. Louis in the fall of 1913. Originally the Home was open but eight months out of each year. In the fall of 1918, however, it was decided to keep the Home open for the entire year.

There are also two homes in Chicago, Rest Haven for women and girls, opened in 1912, and Rest Cottage for men and boys, opened in 1913. They have a combined capacity of forty-five beds and in addition the Chicago Jewish philanthropies utilize a non-sectarian home for women and children which has a capacity of thirty-two beds.

The Jewish Home for Convalescents at Grand-View-On-The-Hudson, was established by the Federation of Roumanian Jews of America, in June, 1916, under the name of the Solomon Schechter Memorial Jewish Home for Convalescents. Lack of adequate funds precluded the installation of necessary facilities for maintenance during the winter months and the home closed its doors for the winter almost immediately following its foundation (in September, 1916). Application for incorporation was made to the State Board of Charities in February, 1917, which was granted under the name of Jewish Home for Convalescents. The institution was reopened in June, 1917, and it is the hope of the Federation of the Roumanian Jews to secure its continuous existence.

The Home is non-sectarian and cares for con-

TABLE V

DEVIATIONS FROM NORMAL WEIGHT IN 114 CHILDREN RETURNED FOR FURTHER TREATMENT

36, or 31.5 per cent, were above the normal weight for age
72, or 63.2 per cent, were below the normal weight for age
6, or 5.8 per cent, were normal weight for age

valescents of both sexes between the ages of sixteen and sixty. The Mosaic dietary laws are strictly observed.

The institution has a capacity of 124 beds but the census, because of inadequate funds, has never been near the full capacity. Thus on January 8, 1918, there were about 7 patients. According to the daily record, the minimum number of patients cared for at the home on any one day since June, 1917, is 5; the maximum is 19. Rates in the ward are \$5 to \$7 per week; for private rooms \$10; patients unable to pay are given free care. Of the 211 inmates from June 17, 1917, to December 31, 1917, 164 were free patients. Applications were referred by eighteen hospitals, one clinic, one settlement, one agency for the tubercular and by private individuals. The nominal length of stay is two weeks but care for periods ranging for two to eight weeks is frequently extended on the recommendation of the matron in charge of the institution and the visiting physician.

Restrictions in Classes of Patients

Applicants excluded from admission are cardiaes as well as those suffering from tumor, tuberculosis, contagious diseases or those requiring surgical attention as diagnosed by one of the examining physicians of the institution.

There is also a small convalescent home operated by the Frauen Verein of Boston. This Home is only for convalescent women, and during the year of 1917 it cared for 122 patients. The capacity is about twelve.

It will be interesting to recount some of the work and results of the Convalescent Home in Cincinnati. To this end we have analyzed the cases handled at the home for the past four years.

The accompanying table (Table I) shows the number of patients at the Home during the period as well as the duration of their stay. We realize that the data presented is extremely scanty, but we are still in the experimental stage.

It can be seen from Table I that almost two-thirds of all the patients remained in the Convalescent Home for more than two weeks, the length of stay contemplated when the Home was opened. Almost one-fifth remained in the Home for eight weeks and almost 6 per cent for a period of from eight to twenty-eight weeks. The total number of patients handled during the period under survey was 1,716.

The following table shows the causes for which patients have been sent to the Home.

It can be seen from Table III that at least half of the patients at the Convalescent Home were sent there for preventive work concerning such causes as anemia and general debility, rather than

as post-hospital cases. The general gain in weight experienced by the various age-groups is worked out in Table IV.

It can be seen from Table IV that of the total 1,716 patients only 98, or 5.7 per cent, showed loss in weight. It is evident that by far the majority of the patients gained five pounds, 1,102, almost 70 per cent, falling within this category. As was to be expected, the largest proportionate gains are shown in the age groups 17 to 31.

There is quite an insistent discussion as to whether patients discharged from the convalescent homes relapse into their former conditions, more particularly with reference to the cases of anemia and general debility. For this reason analysis has been made of all data relating to recurrent cases sent to the Home. It has been mentioned that special stress has been placed on the convalescent care of children under sixteen years of age. During the period of this survey 477 children in this category have been cared for. It becomes apparent from the tabulation (Table V) given that more than three-fourths of all the children cared for maintained the gains achieved by their care at the Home.

A more minute study was made of the 114 children who required to be returned to the Home for special care and the results are developed in Table VI.

The analysis presented in Table VI has given due allowance for the changing normal weight due to increase in age. It shows that almost two-thirds of the children who had to be returned for further treatment deviated more from the normal after having been discharged from the Home.

Promotes Community Betterment

The Convalescent Home, properly functioning, should be utilized as an integral part of both the health work and the relief work of the community. It may be stated here that the scheme under which the United Jewish Charities of Cincinnati operates, which vests in the superintendent, the executive authority of all the constituent bodies of the Federation, makes possible proper planning for all of the organizations. Our experience tends to the conclusion that convalescent care accomplishes most when emphasis is placed upon the side of prevention.

There is a corollary of this particular phase, corroborated by the experience of the Loeb Home in New York as well as the Convalescent Home in Cincinnati that when emphasis is placed upon this particular side of the problem by sending large numbers of children to the convalescent home, the home rapidly ceases to become a place

to which true convalescent adults can be sent. Even anemic children are noisy and possibly we should contemplate the establishment of a separate institution for these children and maintain the Convalescent Home for its original function. In conclusion, may we once stress the necessity of including in the scheme of community enterprise a Convalescent Bureau or Home to insure a proper emphasis upon this particular phase of health work?

LAW FOR THE DOCTOR

BY LESLIE CHILDS, ATTORNEY AT LAW, INDIANAPOLIS,
INDIANA*

Physician's right of recovery for emergency service rendered unconscious person.

There are a number of cases in the reports in which it was attempted to hold the person summoning the physician to the aid of one suddenly stricken or injured responsible for the value of the physician's services. The holdings in these cases are far from uniform, but it is believed that the true principle, as enunciated in many of them, is that the person summoning the physician is, in the eyes of the law, the agent of the stricken or injured one, the reason given being that were this not so one would hesitate to call aid for a stranger, no matter how grievously injured, if by the act he were to be made financially liable for services rendered. Such a rule would tend to make men hard hearted, inhuman, and to stunt and stifle all the finer humanitarian impulses valued by noble men and women the world over. The law has never pursued such a policy.

But cases wherein the physician has sought to hold the administrator of the estate of one to whom he rendered emergency service while unconscious are exceedingly rare. The case of Cotnam vs. Wisdom, 83 Ark. 601, is however, one of this kind and is interesting not only from a standpoint of fact, but of law as well. The facts, in so far as material to this discussion were as follows:

Mr. A. M. Harrison was seriously injured by being thrown from a street car, and the plaintiffs, being physicians and surgeons, were summoned to give him medical aid.

In the hope of saving Harrison's life, he being unconscious at the time, they performed an operation. The operation proved unsuccessful, the patient dying without regaining consciousness. Plaintiffs presented their bill to the administrator of the estate for the value of their services, and the administrator refused to allow the claim. Suit was then brought to enforce payment.

The administrator refused to allow and pay the claim on the ground that it could not be charged to Harrison's estate because there was no contract between Harrison and the plaintiff's either express or implied, the contention in part being set out in the following language:

"Harrison was never conscious after his head struck the pavement. He did not and could not, expressly or impliedly, assent to the action of the Appellees (doctors). He was without knowledge or will power. However merciful or benevolent may have been the intention of the appellees, a new rule of law, of contract by implication of law, will have to be established by this court in order to sustain the recovery."

In replying to this contention the Supreme Court in part said: "Appellant is right in saying that the recovery

must be sustained by a contract by implication of law, but is not right in saying that it is a new rule of law, for such contracts are almost as old as the English system of jurisprudence. They are usually called 'implied contracts.' More properly they should be called 'quasi contracts' or 'constructive contracts.' " Then, quoting from the case of Seeva vs. True, 53 N. H. 627, continued: "That an insane person, an idiot, or a person utterly bereft of all sense and reason by a sudden stroke of accident or disease may be held in assumption for necessaries furnished to him in good faith while in that unfortunate and helpless condition."

The court in effect held this case to fall within the above rule and that the plaintiffs were entitled to recover for the value of services rendered, holding that where a person had met with an accident that rendered him unconscious, and a physician was summoned, the physician could recover the value of the services on the ground of an implied contract.

In this particular case the plaintiffs obtained a judgment in the lower court. The Supreme Court refused to affirm this judgment on the grounds that certain evidence had been allowed to go to the jury touching the final distribution of Harrison's estate that was not relevant and was of a prejudicial nature.

The language used by the court, and the method of reporting the different steps in the procedure is not as clear as in some other reports from the same jurisdiction, but the conclusions are in accord with the great weight of authority, and no doubt are correct, and the probabilities are that this holding would be followed in a similar case in any other jurisdiction.

RED CROSS PEACE PROGRAM

The plan of the Red Cross public health campaign calls for cooperation with other existing health-promotion and disease-prevention organizations throughout the United States, acting by itself where no health agency now exists, in an effort to reduce the high mortality due to preventable disease and to improve general health conditions. Public health nursing will be one of the important features of this campaign. Red Cross public health nurses will be assigned to many small communities.

The seven thousand public health nurses in the United States are far too few to meet the ever-increasing demands for their services and funds are needed for the establishment of scholarships for the post-graduate training of nurses returning from Europe for this specialized public health work, for the development of the necessary teaching staffs and for research work.

Red Cross Home Service among the families of American soldiers and sailors has brought out the important fact that in 90 per cent of the places where Home Service is now operating there is no other social work agency. Accordingly, there is an imperative demand, national in scope, that this service, with its thousands of highly trained workers, be continued and expanded. . . .

Where social agencies are established, the Red Cross will act as a cooperating and coordinating organization when requested to do so.

As always in its long history of general usefulness the Red Cross must hold itself ready for instant relief service in time of public disaster, such as great fires, floods, cyclones, shipwrecks, earthquakes, pestilence, famine and epidemics. Experience in the war and the great organization built up through that emergency will make this branch of Red Cross activity more effective than ever before.—*The Red Cross Bulletin.*

*The sixth of a series of articles on "Law for the Doctor," written for MODERN MEDICINE by Leslie Childs.

AIR CONTROL: THE NEXT GREAT STEP IN HOSPITAL PRACTICE*

IN THE WAR against Germany the world learned that control of the air is absolutely essential to victory. In the next great war against disease the same lesson must be learned, although in another way. Whatever we may believe in theory, the general practice in hospitals is to proceed as if the following conditions of the air were desirable:

1. An average temperature not lower than 68 degrees.

2. As little variation of temperature as is consistent with keeping the air pure and fresh.

3. Whatever degree of humidity the weather may happen to determine; that is, a relative humidity of 10 to 15 per cent on very cold winter days, and every other degree of humidity up to 100 per cent on wet days in summer.

No one of these conditions is correct. The first is a little wrong; the second, decidedly wrong; and the third would be criminally wrong were it not due to ignorance. In place of these unhealthful conditions every up-to-date hospital ought to substitute the following:

1. An average temperature of about 64 degrees for day and night together.

2. As much variation as possible, provided the patients do not become chilled.

3. A relative humidity of about 70 per cent when the mercury stands at about 65 degrees. In winter the humidity may have to be somewhat lower if 70 per cent causes too much condensation on the cold walls.

The proof of these statements is found in an article by Professor Huntington in the first number of *Modern Medicine*, and in his new book, "World Power and Evolution." He has made a study of the relation of temperature and humidity to about sixty million deaths in a dozen or more countries. About four hundred thousand of these deaths occurred in New York City during a period of eight years, and were examined in relation to the weather on the *day* of their occurrence. Nearly nine million more, in France, Italy, and the United States, were treated similarly with the *month* as the unit, each city being studied separately. The other fifty million were examined sufficiently to determine that they agree with those studied more minutely. No previous investigation of health in relation to climate has been made on anything like so vast a scale or with so much precision and detail. This fact, coupled with the remarkable agreement between widely separated parts of the world, makes it the duty of every progressive physician to study Professor Huntington's results and apply them to his own

particular problems. The chief results may be summarized as follows:

1. For the white race the optimum or most favorable temperature, so far as physical health is concerned, is an average of 64 degrees for day and night together. That is, the thermometer may rise to 70 or even 75 degrees by day and fall to 60 or 55 degrees by night.

2. The optimum temperature is practically the same no matter whether people live in the cold north or the warm south. Even among negroes it is no higher than 68 degrees and perhaps lower. There appears to be almost no such thing as real acclimatization involving a fundamental change of physique. An unfavorable climate merely causes man's activities to proceed at a slower rate or on a different level.

3. Variability, both from season to season, and day to day is highly favorable. The value of changes from day to day, however, is much less at low temperatures than at high. Variability involves movement of the air, a matter of much importance.

4. The optimum humidity varies somewhat according to temperature, but not so much as is generally supposed. On the other hand, the effect of the relative humidity of the air is much stronger than is usually realized, and quite different from our traditional belief. On days with an average temperature of 64 degrees, the ideal relative humidity averages about 80 per cent; that is, on clear days dew falls at night, while at noon the humidity falls to about 60 per cent. At higher temperatures the humidity should be lower than at 64 degrees, but, contrary to the general belief, a decidedly low humidity is distinctly harmful. In fact, if we include the whole United States the health of the country suffers almost as much from dry summer heat as from damp summer heat. At temperatures below 64 degrees—and this point is most important—the value of moist air and the harmfulness of dry air become more and more apparent. The wettest kind of weather would be the most favorable if it were not too monotonous and if our houses and clothes did not become damp. Damp air with dry clothing and variable temperatures is the ideal.

The preceding generalizations have a most direct and important practical application. The first aim in hospital wards should be to have an average temperature of about 64 degrees for day and night together. This, of course, can be easily accomplished. A *uniform* temperature of 64 degrees, however, is not advisable, for any sort of uniformity is weakening. That is one reason why people are so sensitive to drafts at the end of the

*Editorial from *The Modern Hospital*, Vol. XIII, pp. 201, 1919.

winter—far more so than in the fall when they are used to a variable temperature, and have not been softened and weakened by the warm monotony of our winter houses. Hence, in the hospital, the temperature should vary. Starting at 58 or 60 degrees in the early morning, the temperature should rise to about 68 degrees during the next hour or so. After staying near that level for perhaps a couple of hours it should be reduced by opening the windows or in some other way, care being taken not to cause drafts or to make the change too sudden. After the temperature has fallen from 4 to 8 degrees during the course of perhaps fifteen minutes, it should gradually rise again, the rise being slower than the fall. This process should be repeated three or four times during the day, while at night it should also take place in the same way except that the low temperature should be more pronounced and continue longer.

The best degree of variability has not yet been determined, but it can easily be ascertained by experiment. The two essentials are, first, that there should be variations, and, second, that they should not be so great as to chill the patients. Newcomers and others who are particularly sensitive should be put in wards where the variation is slight and then gradually inured to greater variability. It must be remembered, however, that if the air is properly moist, as explained below, the chilling effect of a drop of temperature and of moving air will be much less than under the dry unhygienic conditions which prevail in most hospital wards in winter.

Turning now to moisture, Professor Huntington's data show that in winter the damper months have from 5 to 30 per cent fewer deaths than the dry months of similar temperature. This is true in France and northern Italy as well as most parts of the United States—everywhere, apparently, except where the climate is so warm that the houses are not heated. Obviously the increase in the death rate in dry winter weather is due to the extreme aridity of the heated air within doors. Similar aridity is probably the reason for the excessive death rate in dry cities like Cairo and Lucknow, much higher than in moister tropical cities like Bombay and Calcutta. What is needed in our hospitals in winter is moist, variable air like that which conduces to such excellent health in October and May.

It is easy to humidify the air. Professor Huntington has explained an inexpensive method in the appendix of his "World Power and Evolution." The essential point is to supply a large evaporating surface. This can easily be done by placing under each radiator or near each register

a pan of water. The lower ends of absorbent cotton cloths lie in the pan, while the cloths are spread out above and suspended from horizontal strings or rod. If such cloths are placed behind radiators they are both inconspicuous and effective. Their area can easily be varied to meet the demands of different kinds of weather. While the ideal air for the lungs and body should have a relative humidity of 80 per cent at a temperature of 64 degrees, practical considerations render that too high. If 60 per cent can be maintained at that temperature, or let us say 50 per cent when the temperature rises to 68 degrees, it will serve admirably. With such humidity and a variable temperature, the health of hospital patients should show a marked improvement.—*The Modern Hospital*.

OCCUPATIONAL THERAPISTS IN CONFERENCE

At the third annual conference of the National Society for the Promotion of Occupational Therapy which was held at Hull House, Chicago, September 8 to 11 inclusive, the occupational aide was eulogized, and the conviction was generally expressed that occupational therapy offers an ever-broadening field for women trained along that line.

The growth of the society has been phenomenal. When it was founded three years ago, six people were present at the meeting which was held in New York. At the third conference—which was the first really large one—more than three hundred were in attendance, and a large number of those not already members were admitted to the organization.

The sessions were held at Bowen Hall, Chicago State Hospital at Dunning, and the Henry B. Favill School of Occupations. Mrs. Eleanor Clarke Slagle, superintendent of the occupational therapy department of Public Welfare of Illinois, and director of the Henry B. Favill School of Occupations, after some friendly rivalry was declared president. Dr. Herbert Hall, Devereaux Mansion, Marblehead, Mass., was elected vice-president; Louis J. Haas and Miss Marion R. Taber, secretary and treasurer, respectively, were re-elected. Four new committees were appointed to have special oversight in all matters pertaining to tuberculosis, mental and nervous diseases, cardiac afflictions, and orthopedics. Douglas McMurtrie, of the Red Cross Institution for Disabled Men, New York City, was appointed chairman of the International Committee.

The program consisted of addresses by men and women who have successfully demonstrated the benefits of occupational therapy in practically every line to which it has been considered applicable.

Difficulties encountered by the workers were brought out in the addresses and enthusiastically discussed in the Round Tables. The one most frequently to be overcome is the apathy of the patient, and the aides feel that it is indeed a red-letter day when they get the obstinate ones sufficiently interested to "cuss" over what seems to them the intricacies of their first little problems. Another difficulty is lack of cooperation between ward surgeons and the aides and social workers.

THE MONTH IN MEDICINE

Survey of Current Medical Literature with Editorial Comment

WALTER W. HAMBURGER, M. D., Editor

IMMUNITY OF CITY-BRED RECRUITS

ONE lesson practically all wars have taught has been that immunity to acute infectious diseases in the recruits has some direct relationship to the previous life of the recruits, and in this respect the late war is no exception. It has been stated several times that soldiers coming from the more densely populated urban districts were less susceptible to the acute epidemic diseases of camps than were those coming from rural or more sparsely settled regions.

Love and Davenport¹ have recently summarized the records in the Surgeon General's office with regard to the incidence of measles, mumps, meningitis, and pneumonia, and they find, particularly in the first three diseases, that the incidence bears an inverse relationship to the density of the population in the districts from which the men were recruited. It made no difference where the men camped, the same relationship was established. For instance, in two camps in Texas very close to one another the study of the measles incidence reveals the fact that one camp composed of seasoned New York National Guardsmen showed an exceedingly low percentage of measles cases, while the neighboring camp, composed of men from the rural districts of the South showed the highest incidence of measles.

In the Great Basin and in some of the districts of the Northwest where the population is comparatively small, it was found that the morbidity statistics did not run inversely to the density of the population. This fact, however, is explained on the ground that a large percentage of the young men coming from such districts were not born there but migrated from more congested parts of the country where they were born.

Various hypotheses are put forward by Love and Davenport in explanation of the apparently proved immunity of the city recruit as compared with his country brother, and they are inclined to believe in a non-specific immunity produced by one infectious disease against not only itself but

against other infections. This thought follows the ideas suggested by Jobling and his co-workers in their study of non-specific reactions. An epidemic of measles running through a community results in increasing the resistance of that community not only to subsequent measles, but also to other infectious diseases.

INFLUENZA

JUST about a year ago the pandemic of influenza struck the United States, and it is possible that by the time this note is printed a second season of respiratory diseases may already be here. During the epidemic of a year ago opinion was divided as to whether the concurrent bronchial pneumonia was a complication or part of the clinical picture. Bloomfield² and other workers at Johns Hopkins Hospital were of the opinion that bronchial pneumonia was a complication of the influenza infection; and in further support of their contention they have recently published a series of roentgenograms of the lung in cases of influenza in which there were no clinical signs of pneumonia. These pictures lend support to their view that even when the disease lasts longer than three or four days there is not necessarily present any pulmonary involvement.

With the clinical picture and the etiology of the pandemic still unsolved, it would be interesting to study more intensively this year various aspects of the disease. The handicaps under which medical men were compelled to work last year have been removed in great part by the cessation of hostilities and a return to civil practice of a large proportion of physicians.

Of like interest is the communication of Bloomfield and Mateer³ on the disappearance of a positive tuberculin reaction during the febrile period of influenza. In the literature to date practically

1. Love, A. G., Lt.Col., M.C., U.S.A., and Davenport, Charles B.: Immunity of City-Bred Recruits. *Arch. of Int. Med.* 1919, xxiv, 129.

2. Bloomfield, Arthur L., and Waters, Charles A.: The Correlation of X-Ray Findings and Physical Signs in the Chest in Uncomplicated Epidemic Influenza. *Bull. of the Johns Hopkins Hosp.*, 1919, xxx, 342:252.

the only acute illness which was associated with disappearance of the von Pirquet test was measles. These authors have shown, however, nineteen cases of true influenza in which the reaction to dermal tuberculin tests disappears and again appears during convalescence. Many investigators have pointed out other similarities between measles and the pandemic.

THE PATHOLOGY OF INFLUENZA

WHILE countless papers have been published concerning the clinical aspects, bacteriology, and treatment of influenza, and while several papers have been published concerning the pathology of the lungs in influenza, relatively little has appeared concerning the general pathology of the recent epidemic. Indeed, one might say that so much attention and emphasis have been given to the respiratory tract in influenza that the other systems of the body have to some extent been lost sight of.

In view of these facts, Lucke, Wight and Kime's careful and complete study of the pathologic anatomy of 126 definitely proved, fatal cases of influenza at Camp Zachary Taylor and Camp Knox, Ky., is particularly noteworthy. These 126 cases were selected from a considerably larger number of autopsies by ruling out all patients who clinically gave evidence of such pre-existing disease as tuberculosis, measles, etc.

External Appearance.—The necropsies were performed under ideal conditions, usually within a few hours after death. The general appearance of these bodies showed the face, as well as almost the entire body to be of a dusky color, sometimes even purplish black. In about two-thirds of the cases a bloody, sometimes frothy, discharge exuded from the nostrils and the mouth. The cadaveric rigidity seemed to be somewhat delayed. The superficial glands were never found palpably enlarged. Edema, although always looked for, was never present and this should be emphasized in view of considerable renal changes. The joints were never enlarged, nor was any arthritic condition demonstrated at necropsy, although it was sometimes seen clinically.

The Skin.—Two types of skin lesions were encountered—purpura hemorrhagica in about 20 per cent and toxic necrosis of sebaceous follicles in about 60 per cent of the cases. Jaundice was present in about 10 per cent.

Subcutaneous Tissues.—Generalized emphysema was present in three cases. "We believe the

mode of origin of this to lie in ulcerative or erosive bronchiectasis with escape of air in the peri-bronchial tissue and thence to the mediastinum and subcutaneous tissue."

Muscles.—Zenker's hyaline degeneration of the rectus muscles was observed in about 10 per cent of the cases.

Peritoneum.—Peritonitis occurred three times in chronic influenza.

Blood Vascular System.—Extreme congestion with areas of hemorrhages, was commonly present.

Pericardium.—Pericarditis occurred seven times.

Heart.—The heart muscle was practically always affected. This is especially interesting because of many conflicting reports to the contrary. In more than 90 per cent of the cases more or less relaxation of the right heart was present; in more than 80 per cent an associated cloudy swelling occurred. Microscopically, there was an acute parenchymatous degeneration and vacuolization. Endocarditis was seen only once.

Respiratory System.—The accessory nasal sinuses presented purulent or sanguinopurulent involvement in about 85 per cent of the cases. Microscopically, an acute sinus catarrh was almost always present.

Pleurae.—The pleurae were involved on one or both sides in more than 80 per cent of the cases.

Lungs.—The pneumonitis was generally lobular in type. The nonconsolidated lung tissue was generally very hyperemic. The essential pathology of true influenzal pneumonitis seemed to be extreme hyperplasia of the pulmonary epithelium.

Spleen.—The spleen was usually flaccid, occasionally mushy, and generally bloody.

Suprarenals.—The adrenals were usually congested and somewhat edematous; in three cases a frank hemorrhage was seen. Lipoid exhaustion was the most notable change.

Kidneys.—The kidneys were generally enlarged, flaccid, and congested. The renal changes seemed to be in the nature of a parenchymatous degeneration with edema rather than of a productive nephritis.

Liver.—The liver was definitely increased in size and weight. Cloudy swelling was common. In one instance a true acute yellow atrophy was encountered, and in several others necrotic changes which could be looked on as precursors of yellow atrophy.

Brain Membranes.—The *dura mater* was congested in about one-third of the cases. Suppurative meningitis, due to secondary invaders, was present in 20 per cent.

3. Bloomfield and Mateer: Changes in Skin Sensitiveness to Tuberculin During Epidemic Influenza. Bull. of the Johns Hopkins Hosp., 1919, xxx, 342:238.

4. Lucke, Baldwin, M.D.; Wight, Tonybee, M.D.; and Kime, Edwin, M. D.; Pathologic Anatomy and Bacteriology of Influenza, Arch. Int. Med., 1919, xxiv, 154.

Brain.—The brain was generally congested, hyperemia and focal hemorrhages being very frequent. The changes were more marked in the cerebrum, while the cerebellum, medulla, pons, and spinal cord showed relatively slight alterations.

Five of these 126 cases had an average duration of sixty days and were regarded as chronic influenza, presenting certain characteristic features. All of the patients were markedly emaciated. The serous membranes were frequently involved. The heart always showed cloudy swellings and hydropic degeneration. The lungs evidenced pneumonic processes of long standing. The kidneys presented pronounced glomerular nephritis.

The conclusions of these authors are particularly interesting and are quoted in full.

(1) The incidence of influenza is greater among whites than among negroes, but the mortality rate is higher among the latter.

(2) The average duration of life is fourteen days; in the early part of the epidemic the average duration of life is considerably shorter, and in the latter part considerably longer.

(3) The anatomic and bacteriologic findings vary with the stage of the epidemic and of the disease, and depend to a certain extent on the endemic bacterial flora. Earlier in the epidemic the disease was more fulminating, and during this time the *Bacillus influenzae* was most often found; as the epidemic progressed and the attacks lengthened, secondary invaders appeared more and more frequently and corresponding anatomical changes were found.

(4) Influenza produces widespread changes throughout the body and, while the lungs commonly present the most spectacular lesions, pronounced alterations are also encountered in the nervous, cardiovascular, and other systems.

(5) The most general changes produced by influenza are pronounced congestions, hemorrhages, toxic degenerative lesions, and hemorrhagic inflammations. Hyperemia and hemorrhages are especially striking in the meninges, brain, serous membranes (petechial hemorrhages), skin (intense cyanosis, purpura hemorrhagica), lungs, spleen, liver, and kidneys. Examples of toxic degenerations are Zenker's hyaline degeneration of the rectus muscles; conglutination and hyaline thrombosis; hyaline degeneration of vascular walls; hyaline degeneration of germinal centers of splenic follicles; focal necrosis of the liver, pancreas, and suprarenal; toxic ganglionic changes and edema in the nervous system; and cloudy swelling of parenchymatous organs. Hemorrhagic inflammations are exemplified in early pneumonitis and pachymeningitis; productive inflammations are uncommon and are confined to the later stages of the disease.

(6) The true pneumonitis of influenza is characterized by extreme proliferation of pulmonary epithelium, pronounced hyperemia, and hemorrhages. The commonly present secondary invaders produced a pneumonitis which grossly and microscopically consists of a number of separate, dissimilar pathologic processes. Microscopically, a lobular pneumonia, with a tendency to become pseudolobar, and with a mixed, smooth and granular cut surface, is present. Microscopically, there are four distinct types

of exudates, often within the same microscopic section, but distinctly independent. These are: Catarrhal, fibrino catarrhal, fibrinopurulent, and purulent in type.

(7) Throughout the disease there is a relative paucity of polymorphonuclear leukocytes and a proliferation of the lymphoid tissue; this would seem to point to myeloid intoxication and to lymphoid stimulation.

(8) Chronic influenza is characterized by relative absence of vascular changes, connective tissue proliferation, and diffuse suppuration.

(9) The influenza bacillus, although not found in every case, was present in a sufficiently high percentage, and often enough in acute fatally ending infections to consider it, if not the prime cause, at least the most important indicator of epidemic influenza. At all events its appearance with the epidemic and its relative absence prior thereto, using the same cultural methods, strongly strengthens the assumption of its pathogenic rôle.

(10) *Bacillus influenzae* was easily cultivated early in the epidemic and during the recrudescence of the last period, and this corresponded with the fulminating pathology of these stages.

(11) As the patients lived longer and the epidemic progressed, bacterial agents, well established at this post as the cause of respiratory tract disease, notably the non-hemolytic streptococcus and pneumococcus, appeared as secondary invaders and modified the bacterial readings and anatomic changes.

(12) The nonhemolytic streptococcus, it should be stated, was a frequent commensal in the earliest part of the outbreak.

(13) It is noteworthy that all the above secondary invaders were more fatal in symbiosis than alone.

(14) Later in the epidemic the hemolytic streptococcus assumed the ascendancy as a tertiary invader crowding out the secondary invaders, and was of especial importance in cases of long duration. Staphylococcus and *M. catarrhalis* made their appearance toward the end of the epidemic and to some extent modified the pathology.

We wish to enter a plea for the reading and recording of total bacterial flora and their symbiotic relationships; by this means too great weight would not be placed on single observations, like typing of pneumococci. Furthermore, in the study of this disease, observation should be made on the stage of the epidemic and the individual cases. By this method the proper relations of the various organisms can be calculated.

Discussion.—These carefully studied cases of influenza are worthy of much thought. It would seem that they point the way to our conception of the clinical entity known at present as influenza and, as these authors state, "Influenza produces widespread changes throughout the body, and while the lungs commonly present the most spectacular lesions, pronounced alterations are also encountered in the nervous, cardiovascular, and other systems." This conception may be considered the keynote of the problem, namely, that this dread disease is a generalized infection, gaining entrance to the body through the respiratory tract, but affecting to a greater or less degree the entire body. In the clinical handling of influenza patients then, this conception of a generalized widespread infection should be constantly borne in mind; and in the examination,

diagnosis, and treatment of the disease, one should plan his therapy and be constantly on the lookout for possible harm to all organs. While these studies are illuminating, in another sense, they are disheartening, for they show the futility of any single drug or measure to combat individual symptoms and isolated disease processes. They emphasize again the need of specific therapy and prophylaxis and stress anew the fact that early, continuous, and prolonged rest in bed is the only real measure of value that we have at the present time.

THE CYANOSIS OF INFLUENZA

IN THE recent epidemic of influenza with its accompanying pneumonia the unusual frequency of cyanosis was striking, and was in fact one outstanding feature of the epidemic.¹ Thus Stadie² introduces his recent article on studies of the oxygen content of the arterial and venous blood of pneumonia, and its relation to cyanosis. Any additional light on this feature of the recent epidemic of cyanosis is highly desirable for it was the experience of everyone throughout the country that probably a new factor was dominant in the causation of this striking symptom and was unrelated to usual experience in pneumonia and heart conditions, namely, that cyanosis is an evidence of cardiac failure, widespread lung consolidation, or insufficient oxygenation of the venous blood in the pulmonary circuit.

Of additional interest in the results of this work itself, is the fact that Stadie has confirmed the opinion of Hurter that puncture of the radial artery is a safe procedure, and has described in detail how this technic is carried out. Likewise, the introduction of the new term "oxygen unsaturation" (Lundsgaard) as the difference between oxygen content and total oxygen capacity must be clearly appreciated. "The unsaturation may be expressed either as cubic centimeters of oxygen per 100 cc. of blood, or as percentage of the total oxygen capacity."

Stadie classifies the possible causes of cyanosis under three heads: (1) disturbance of the capillary bed; (2) changes in the hemoglobin; and (3) admixture cyanosis. His final conclusions as to the final causes of influenza-pneumonia therefore are as follows:

It is evident that the cyanosis of pneumonia patients is due to the incomplete saturation of venous blood with oxygen in the lungs, and that the various shades of blue observed in the distal parts are caused by an admixture of reduced hemoglobin and oxyhemoglobin in the superficial capillaries.

Likewise his conclusion that oxygen consumption, that is, the difference between arterial and

venous contents, was within normal limits, indicating that the cardiac output was not diminished in the cases of pneumonia studied.

STUDIES ON CYANOSIS—PRIMARY AND SECONDARY CAUSES

LUNDSGAARD³ considers that abnormally high oxygen unsaturation is the primary cause of cyanosis but that no proportionality exists between the intensity of the blue color and the amount of reduced hemoglobin. The explanation of this lack of proportionality he discusses in what he calls the "secondary causes of cyanosis." He shows that when the capillary oxygen unsaturation, which normally is about 2 to 3 volumes per cent, is increased to about 6 to 7 volumes per cent, cyanosis actually appears.

He shows further that this increase is produced either by an abnormally great reduction during passage through the capillaries, or by a state of partial reduction on the arterial blood entering the capillaries, the first condition occurring when the blood flow is retarded, as in decompensated heart conditions, the second in certain lung and heart diseases, when the alveolar oxygen tension is greatly decreased.

Discussion.—These recent studies on cyanosis are in a sense to be considered merely as introductory, and as stating the problem. Confirmation and elaboration of this work must and surely will come within the near future and we may confidently look forward to interesting results in this unexplored field. From a clinical standpoint, already Stadie's work is suggestive in showing that the oxygen consumption of these influenza-pneumonia patients to have been within normal limits, indicating that in spite of pathological change in the heart muscle, the cardiac output was not diminished. The fact that the cyanosis is due to the incomplete saturation of venous blood with oxygen simply points the way for the need of more extended work as to the causes of this incomplete saturation.

In view of the fact that the oxygen consumption is normal, thus ruling out the cardiac element, one could speculate that the failure to saturate the venous blood in the lungs with oxygen must in some way be related to local changes in the lungs or pulmonary vessels, or to chemical changes preventing the more complete saturation of venous blood.

SCABIES IN RELATION TO THE COMMUNITY

BY A. RAVOGLI, M.D., CINCINNATI, OHIO

WITH the returning soldiers from Europe, and from the cantonments it happens quite often to meet cases of scabies which have passed unrecognized. We have seen persons afflicted with this affection as long as from two to four months. They had consulted several physicians, nearly all of whom had agreed that they were suffering from eczema produced by acidity of the stomach. As a consequence the eating was cut down, no meat, no sweet cakes, no ice cream, etc. That they have eczematous conditions of the skin, there is no doubt; but these are the results of scratching with the finger nails.

Everybody knows that scabies is due to the presence of a mite, an *animalculus acarus scabiei* which bores into the epidermis and makes this layer of the skin its habitat. We must laugh at the recommendations of dieting to cure scabies.

The Offending Organism

Scabies is a local disease, highly contagious, produced by the *acarus scabiei*. It is to be noted that of the *acarus* there are male and female. The male has short life, is found only rarely between the crusts, fecundates the female, and then dies. The female is twice the size of the male; it bites the epidermis and hides itself under the cover of the epidermis. It has a system of mandibulae with which it bites the epidermis, and a suction organ to suck the fluid of the deep epidermal cells for its nutrition.

The *acarus* has some long bristles at the posterior legs which prevent it from going back; in consequence, it is compelled to proceed and in this way forms the furrows which is the characteristic sign of the scabies.

When the certain proof of scabies is needed, the *acarus* must be found. Furrows are mostly found in the interdigital spaces, in the penis, or on the upper axillary regions. The furrow is easily recognized as a line somewhat elevated, running in tortuous way, and containing small dark dots. The furrow shows two extremities, one superficial, fringy, where the *acarus* has bitten; it is the point of entrance. The other end is somewhat round, deeper, and it is the place where the *acarus* is embedded. With a flat needle the epidermis is pierced in that point and broken. In raising the needle a whitish oval round body is found hanging. This is placed on a glass slide with a drop of glycerin, or of Canada balsam, and examined under the microscope (Fig. 1). Under a small

power the *acarus* looks like a small turtle, with six extremities when at the state of larva, and with eight, four in front and four in the rear, when full grown. The back shows rows of thorns. The head has six bristles, and four pairs of mandibulae with two feelers. The front legs are furnished with a kind of suckers. The back legs have long bristly hair, which prevent the *acarus* from going back from the furrow. The *acarus* consequently must always proceed, lay the eggs, and after some time dies. The eggs with the body calor are hatched, and the small *acari*, developed, come out of the furrows, especially during the night, crawling on the surface of the skin, and causing unbearable itching, with loss of sleep to the patient. In the furrow, together with the eggs of the *acarus*, small dots are seen, which are the feces. The eggs are oval, and those near the opening of the furrow show the developing *acarus*.

Symptoms to Be Noted

The most interesting feature is the furrow, which is directly produced by the *acarus* entering in the epidermis. It is somewhat elliptic, or appears as a half circle, irregular, one or two millimeters long. Near the furrow often vesicles or pustules are formed, which have nothing to do with the furrow, but are the result of irritation to the skin produced by the *acarus*. The *acarus* in the epidermis travels always slantingly, as it tries to reach the juicy cells of the mucous layer which afford better nourishment. The epidermal cells, deprived of their plasma from the suction of the *acarus*, become keratinous and dry, and the *acarus* is compelled to proceed to find better nutrition. Meanwhile, in the place occupied the eggs are laid. The furrow, which in the beginning is one or two millimeters long, may reach a length of a centimeter.

From the irritation, vesicles and pustules are formed near the furrow, but they do not contain the *acarus*. The pustules are caused by the inflammation, and they are from the papillary layer while the furrow is in the epidermis.

Furrows can be found almost in any part of the body, but the flexion surface of the wrist, and the interdigital spaces show the furrows more plainly. In children and in adults with soft skin, furrows are found in the palm of the hands, the anterior fold of the axilla, the nipples in the woman, the penis in the man, and the navel. In

general furrows are found in every part of the body where the skin is close to the clothes, as at the vest, the buttock, and the thighs. For the general practitioner it is sufficient to look for the furrows in the interdigital spaces, the wrist, the anterior fold of the axilla, the nipples, and the penis.

Eczema a Secondary Condition

Besides the furrows, the patient with scabies shows eczema, which is the direct result of the irritation from the *acarus*, and an indirect consequence of its action.

From the irritation caused by the *acarus*, papules, pustules, vesicles, bullae are produced at the point of entrance, and the young male *acari* may be found under the furrows and under the crusts. These papules, vesicles, etc., are only incidental; they are more pronounced on persons with thin delicate skin. These eruptions prompted the distinction between vesicular, pustular scabies, according to the prevalence of these secondary manifestations.

In children and in delicate women near the furrows on the soles of the feet, bullae, and papules are developed, which are seated underneath the furrows. Moreover eczematous patches are found scattered all over the surface of the body. The itching sensation is very annoying, but in the evening it is nearly unbearable as it seems that in the warm bed the *acari* are made more lively, the young *acari* leave the furrows and, crawling on the skin, look for their nutrition and abode. The patient is compelled to scratch, and by scratching aggravates the eczema as scratching with the dirty finger nails inoculates other parts of the skin. The eczema is spread in small areas mostly around the furrows consisting of papulae and vesicles, which are broken by scratching and are replaced by crusts and bleeding excoriations. Only rarely a diffuse, weeping eczema is produced.

Distribution of Eczema

The eczematous patches are distributed from the anterior surface of the axillæ, the breast to the knees, forming that peculiar ovoid appearance on which Hebra insisted so much for the diagnosis of scabies. The genitals, the internal surface of the thighs, the wrists, the elbows, and also the legs are covered with eczematous patches. Excoriations and pustules are mostly formed in those regions of the skin where the clothes are more tight as the breast, the vest in the woman, the buttock, the scrotum, and the thighs in those who by their occupation are compelled to sit a long time, as in shoemakers, tailors, etc., and in the children held in arms.

In children the incidental eruptions papules, pustules, and crusts are in such quantity as to cover the furrows, and sometimes make difficult the diagnosis. A patient exposed to the contagion of scabies, either by contact with some one already affected, or from sleeping in a bed where some one affected had slept, or using wearing apparel infected with the *acarus*, in a few days begins to be troubled with itching sensation which gradually increases. Furrows appear only fifteen days after the exposure. When scabies spreads over the surface of the body, with perceptible furrows, exposure can be considered to have taken place from six weeks to three months before. Scabies has not any influence on the general health, nor on the internal organs; it causes only the cutaneous lesions described.

Subsides in Febrile Conditions

The itching sensation prevents the patient from sleeping, and this may have some effect on his general health. It has to be noted that during a febrile illness like pneumonia, typhoid fever, scabies will disappear. On account of the high temperature, or of the quality of the nutritious fluid the *acari* die; but the eggs remain and will develop again after the recovery from the illness. This peculiar condition caused what physicians in the past believed to be metastasis of scabies.

Methods of Transmission

The cause of scabies is the *acarus*. This little insect is communicated from man to man, but it can be taken also from animals. The contagium of man to man is the most easy, and the most common, especially from sleeping in the same bed with some one affected with scabies. It can be also transmitted by using clothes, garments, or sleeping in a bed where somebody with scabies had slept. In general it may be said that scabies is transmitted only rarely by short contact in the daytime. Everybody who is interested in skin diseases has handled patients with scabies, and yet has never contracted the affection.

Diagnostic Data

In reference to the diagnosis, we must repeat that which we have already stated in the beginning, that scabies is not easily recognized by the general practitioner, who usually refers the itching sensation to nervousness, or to vasomotor troubles. The patients are treated with internal medicines, with changing diet, but remain annoyed with the itching eczema, when with one or two local inunctions they can be easily cured.

It is not necessary for diagnosis to extract the *acarus* from the furrow, which is usually difficult,

but the presence of the furrows, will prompt the diagnosis. The interdigital spaces, the penis, and the nipples in the woman, show furrows. In some cases furrows are not found in the hands, especially in individuals using much soap or chemicals.

The multiplicity of such lesions as papules, vesicles, pustules, and eczematous patches, scattered in the parts of the body where the clothes are more tight, helps in the diagnosis. In all these cases although the diagnosis is not sure, there is good reason to suspect scabies. The best way is to treat them as scabies, and in a few days all symptoms will disappear. When the cause is removed, the acari have been destroyed, the itching subsides and in consequence the eczema diminishes. Sometimes, especially when using very strong irritating ointments for the rapid treatment of scabies, eczema gets so bad that it needs to be treated as an after effect of scabies. Sometimes the itching lasts for a long time, and only after prolonged treatment does it gradually disappear.

Essentials in Treatment

The rapid treatment of scabies usually causes great irritation. It has to be remembered that

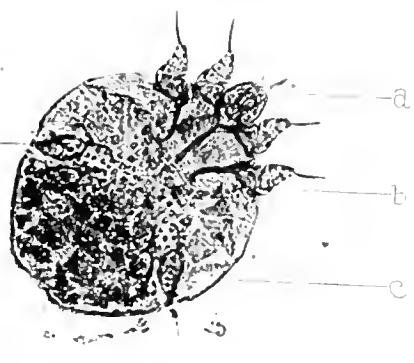

Fig. 1. Female acarus. (a) Mouth with a complicated system of mandibulae, jaws, and a sucker. (b) Anterior extremities furnished with feelers. (c) Posterior extremities with bristly hair, which prevent the acarus from going back.

the *acarus* is in the skin, which is an organ of the body, and in killing the *acarus* the skin is not to be injured. The treatment takes from five days to one week, but during the treatment the patient can do some work. The eczema, an after effect of scabies, takes sometimes two and four weeks to be entirely cured.

Many remedies are capable of destroying the *acari*, at the head of all is sulphur. *Helleborus*, tar, naphthol, balsam of Peru, coal oil, all

Fig. 2. (a) Here the feelers on the front extremities are more perceptible. The four extremities in the rear show it to be an adult acarus. Both are female acari.

form the base of different salves used to treat scabies; but if the applied remedies are not capable of breaking the furrows, dissolving the epidermis so as to reach the *acarus*, scabies may easily recur, for the reason that some *acari* have escaped destruction.

In our practice we have found always reliable the Wilkinson salves as modified by Hebra. The formula is as follows:

R	Flower of Sulfur.....
	Oil of Cade.....	20 gms.
	Green Soap
	Lard	80 gms.
	Pulverized White Clay.....	5 gms.

For a delicate skin we prefer the salve of Weinberg:

R	Styrax Liquid
	Flower of Sulfur.....
	White Clay Pulverized.....	10 gms.
	Green Soap
	Lard	20 gms.

In these salves there is green soap to soften the epidermis, white sand to break the furrows, sulphur and tar to kill the *acari*. The salve produces very little irritation. The salve has to be applied from the neck to the feet, rubbing vigorously so as to break the furrows. One and a half ounces of salve are sufficient for one application. In prescribing according to the age, the sex, and the size of the patient, from four to six ounces

of salve are ordered. The quantity is divided into three parts, leaving a small quantity.

The salve is rubbed strongly all over and some one must help to rub the back of the patient, so that no place is overlooked. After the salve has been rubbed, the same underwear is used; nothing is changed. The patient in the morning can wash the hands and face so as to be able to go to his occupation. The rubbing of the salve is repeated for three successive nights. The patient is told not to take a bath until two days after the last inunction. Meanwhile the little salve left can be used in the evening for the hands, which, having been washed, are liable to contain some *acari*.

The patient may take his bath and wash thoroughly with soap and hot water two days after the last inunction. The reason is to wait until the skin is dry, the shrunk epidermis begins to exfoliate, and all other symptoms of irritation gradually subside. After the bath, the patient has to change all garments, and the clothes have to be fumigated or sterilized, to be sure that no *acari* and no eggs remain.

After the bath some patients still complain of itching sensation; many claim that they are not free, and insist on making some more inunctions. This has to be prevented. The itching sensation is the last to disappear; excessive use of the salve will cause more irritation, and consequently more itching. To relieve the itching a carbolic lotion can be used, dabbing the parts once or twice a day. When the parts dry, cover with starch powder.

R Acid, Carbolic	
Glycerin	aa 5i
Aqua Ros.	
Alcohol	aa 5iii
M. and use externally. Apply as lotion.	

If eczematous eruption should trouble the patient, then it is necessary to cover the places with benzoate of zinc salve, or with a mixture of zinc and calamine, so to cure the remaining eczema.

Ever Present in Working Places

Although scabies is not dangerous, it is dirty and extremely annoying. In factories and working places where there is a congestion of working people, it has to be watched. The physician of the factory should examine every one who scratches his body, because scratching is not natural, and it is usually due either to scabies or to pediculosis.

There is a proverb which says that three things cannot be concealed: love, cough, and scabies. We have seen scabies in people handling dogs, which we have called scabies anamala, and never to be forgotten is the fact reported by Hebra

that the men working in the menagerie of Schoenbrun were affected with scabies. On examination of the camels it was revealed that all were infected with *acari*.

It is a disease which is easily communicated to children by the little girls who take care of the children during the hours that the mother is working in the factory. The little children in arms are kept sitting in the palms and on the wrists of those who take care of them, and the first infection is in the buttocks. When a child has been infected with *acari* when taken in hands by their parents, they too get infected, and this is the way scabies is spread from one to another, and from one family to another. For this reason, when in a factory, college, or school, inmates are found scratching, they must be immediately examined and treated. After the first inunction the workingman under treatment can be readmitted to his work, because there is no danger of communication.

SYMPOSIUM ON NARCOTIC DRUG ADDICTION

The Long Island Medical Journal in its August issue publishes a symposium on narcotic drug addiction. The writers in the symposium are Royal S. Copeland, M.D., commissioner of health, on "The Attitude of the Health Department"; the Honorable Cornelius F. Collins, Justice, Court of Special Sessions, City of New York, on "The Law and the Narcotic Addict"; Sara Graham-Mulhall, on "The New York State Narcotic Commission"; the Honorable Ben A. Matthews, assistant United States attorney, Southern District of New York, on "Medical Practice as Affected by the Harrison Law." Commissioner Copeland in his paper estimates that there are not less than 100,000 drug addicts in New York City alone, which indicates the enormous size of the problem and the importance of the symposium from all points of view.

NEW SCHOOL FOR DENTAL NURSES

The Royal College of Dental Surgeons, Toronto, Ont., with the session of 1919-20 will have a training school for dental nurses. The intention of this course is to train young women for service to both dentist and patient in the practice of dentistry, and to prepare them for public service, to act in the capacity of assistants to dentists engaged in school and hospital dental service. The course will embrace seven months' instruction divided into two semesters. The subjects of the course are: the tooth brush and its use; office routine and management; records, banking and correspondence; assisting at dental chair; knowledge and care of instruments, materials and equipment; assisting with anesthetics; preparation of drugs for dental use; sterilization and sanitation; elementary pathological laboratory technique; elementary prosthetic laboratory technique; radiography; ethics and conduct; school and hospital dental service. The registration fee is ten dollars, and tuition fee twenty dollars for each semester. The first class is limited to fifteen members. Each candidate who successfully completes this course is to be known as a dental nurse and will act entirely as an

assistant and not be trained or permitted to practice as a "hygienist."—*Oral Hygiene.*

THE TREATMENT OF HAY-FEVER

In this article by William Scheppegräll¹ one finds a good review of almost all methods in use at present in the treatment of this baffling disease. The first factor is the removal of the pollens which cause the disease. As is now well known, the spring hay-fever, comparatively rare in this country, is usually caused by the pollen of various grasses; while the autumnal catarrh is produced by the ordinary ragweed. In all cases treated at the Hay-Fever Clinic at the New Orleans Charity Hospital, patients are given charts of nine blocks of their neighborhood with instructions to locate thereon lots that are infested with weeds. The Board of Health is then informed of the presence of the weeds and notifies the lot owners to cut the weeds under penalty of prosecution for violating the grass-weeds ordinance, which apparently is in existence in New Orleans. In 1916 he has shown that special effort to remove the source of the pollen had resulted apparently in a reduction of the spring catarrh by 50 per cent; but the autumnal type was not markedly reduced because of the wide potential radius of the ragweed pollen. When it is impossible to remove the pollen-producing grass and weeds, the patient is instructed to keep away during the season from infested districts.

The effect of rain is two-fold: it causes precipitation of pollen floating in the air; and prevents more pollen from leaving the plant. Furthermore, according to Scheppegräll's experiments, pollen that has been soaked in water loses its toxicity. Although the effect of nasal gauze in the prevention of hay-fever is considered nil, considerable benefit arises from screening windows of rooms in which sick hay-fever patients are, by means of cloth saturated in water.

Surgical procedures on the nose or accessory sinuses do not cure hay-fever patients, but any condition, such as marked spurs, ridges, or deflections, which might cause a concentration of pollen in the obstructed nostril, should be treated surgically. Also, infections of any of the accessory sinuses should be treated as a preliminary to other hay-fever therapy. Calcium chlorid, or calcium lactate, in doses of 15 grains, well diluted, three times a day after meals, is occasionally found of value; and cases associated with asthma have been helped by sodium iodid. The injection of succinimid of mercury, $\frac{1}{6}$ grain in distilled water, has been employed with benefit by Wright, of the United States Navy.

The only local treatment which may help is menthol, two grains to the ounce of liquid petrolatum, used in the form of a spray. Temporary relief is also furnished by cocaine and epinephrin, but the after effect is likely to be bad. The author also uses an instrument for vibratory massage over the inferior turbinal septum and the lower portion of the middle turbinal.

Specific therapy along the lines advocated by Strouse and Frank, in 1916, has been employed by Scheppegräll with apparently unusually good results. Intradermal tests of pollens are made, and injections of the extract given before the onset of the hay-fever season. Scheppegräll starts with 5 units and goes as high as 100 to 200. As soon as the specific pollen appears in the air, the extract injections are reduced and bacterial vaccines employed. Scheppegräll uses either an autogenous vaccine

or, a stock vaccine consisting of many of the organisms usually found in the respiratory tract.

Scheppegräll claims that in a series of 707 cases there were seasonal cures in 49 per cent; marked improvement in 40 per cent; or satisfactory results in 89 per cent of the total number. These figures are decidedly higher than those reported by other investigators. In some cases there was no apparent improvement during the season, but there was relief the following year.

FACTS ABOUT CANCER

The United States Public Health Service in its "Keep Well Series" recently published a concise, instructive statement in which cancer is designated as a curable disease if discovered in time, and a preventable disease if certain definite conditions are avoided. The facts which it is believed every person over thirty years of age should know are summarized as follows:

"(1) Cancer at the beginning is usually painless and its onset for this reason is especially insidious and dangerous.

"(2) Cancer is at first a small local growth which can be safely and easily removed by competent surgical or other treatment.

"(3) Cancer is not a constitutional or 'blood' disease.

"(4) Cancer is not contagious.

"(5) Cancer is, practically speaking, not hereditary.

"(6) Every lump in the breast should be examined by a competent doctor.

"(7) Persistent abnormal discharge or bleeding is suspicious.

"(8) Sores, cracks, lacerations, lumps, and ulcers which do not heal, and warts, moles, or birthmarks which change in size, color, or appearance, may turn into cancer unless treated and cured.

"(9) Probably 60 per cent of cancers of the rectum are first regarded as piles. Insist on a thorough medical examination.

"(10) Continued irritation in some form is the usual cause of cancer. It rarely results from a sudden injury.

"(11) A doctor who treats a suspicious symptom without making a thorough examination does not know his business."

INFANT MORTALITY IN LARGE CITIES

According to a compilation made by the Newark, N. J., Department of Health, that city leads for having the lowest infant mortality rate for the larger cities of the United States. The figures given are based on reported births and reported deaths, and are as follows for a number of cities:

THE INFANT MORTALITY RATE FOR THE LEADING CITIES OF THE UNITED STATES FOR FIRST SIX-MONTH PERIOD, JANUARY 1-JUNE 30, 1919

Cities.	Rate	Births	Deaths Under One Year
Newark	77.1	5,460	421
St. Louis	84.2	6,421	541
New York City	87.2	65,926	5,747
Manhattan	92.0	28,768	2,646
Philadelphia	88.9	20,654	1,838
Baltimore	94.4	8,381	792
Cleveland	96.9	9,392	911
Detroit	107.2	12,382	1,328
Buffalo	121.0	6,238	755
Pittsburgh	133.1	6,782	903
*Chicago	100.2	3,177
*San Francisco
*Milwaukee	103.9	5,348	556
*Boston	104.2	9,256	965

Rates are based on reported births and reported deaths.

*Rate for Chicago was based on estimated births by Chicago Department of Health.

Written at the end of a war which taxed the resources of everybody in the medical profession, this volume stands out as testimony of the devotion to ideals of the English speaking medical profession. It is, of course, impossible to review in detail the many subjects covered by this book. Suffice to say that practically all the recent contributions to therapy have been abstracted and brought together in a readable and concise form. Contributions of the war surgery to the development of functional restoration naturally occupy a large part of the volume; but medical subjects like influenza and diabetes are not neglected. On the whole, the book can be thoroughly recommended to those who want a brief abstract of the very latest contributions to therapeutics.

S. S.

BACTERIOLOGY AND MYCOLOGY OF FOODS. By Fred Wilbur Tanner, M.S., Ph.D., Associate in Bacteriology, University of Illinois.†

The author is to be complimented for presenting a volume of this subject at such an opportune time. Workers in this branch of science should welcome the text with enthusiasm for it rather completely covers the field that previously has been left untouched from a text book standpoint. As is stated in the preface, the author has liberally quoted from other investigators but this we feel he has done with the greatest of prudence and in such a manner that the scope and completeness of the text have been markedly enhanced.

The text is well written and the chapters logically arranged though in some instances the illustrations, of a stock nature, are rather profuse. Each chapter is appended with a very representative and well selected

bibliography, which will undoubtedly be of great value to the reader. The chapter on yeasts and moulds might possibly have been made more extensive from a botanical standpoint; for this is a field the bacteriologists and food mycologist are not usually extensively prepared to invade and a more complete chapter will prove of great value to these investigators and students. The paragraph on cheese is not as complete as most of the text. It is unfortunate that the author has limited his discussion to cheddar cheese. We feel it a just criticism to state that this chapter is decidedly lacking and that this field has been only slightly entered into. Some of the more important products have received no mention.

The general scope of the volume is well indicated by the chapter which covers the work in botulism, which has recently become of great interest to the food chemist and bacteriologist. This work is brought up quite completely and well indicates the up-to-dateness of the text. The author has ably handled, in most instances, each chapter in such a manner.

Unfortunately, there are a few typographical errors that might confuse the reader but these are not many and will probably disappear in a later edition. The author deserves great credit for producing this text. Undoubtedly it will be very popular with workers in its field and we can readily see how it will justly earn such popularity owing to its general completeness and thoroughness. It is a volume that can well be recommended to bacteriologists and food mycologists.

HEALTH AND THE WOMAN MOVEMENT. By Clelia Duel Mosher, A.M., M.D., medical adviser of women, Leland Stanford Junior University.‡

This little book is a revised publication of an address given at the Fourth Biennial Conference of the Young Women's Christian Association of America. It is a sane and wholesome talk for normal women that is calculated to arouse women to become physically equal to the opportunities thrust upon them. Sound health and physical perfection are first requisites.

She decries the traditional handicaps of sex as not inherent structural differences, but as the results of bad hygiene, constrictive clothing, and inactivity of the muscles of the abdomen and diaphragm. The first step in the physical regeneration of women is to alter their attitude of mind in regard to physical disability. Every woman should cultivate the habit of thinking in terms of health. Such discomforts as arise from functional periodicity are largely due to congestion and circulatory disturbances, and are subject to correction by the following simple exercise:

Food in Relation to Industrial Efficiency.

THE morale of a fighting army is quickly destroyed by a scarcity of food. An army will carry on and win battles while short of ammunition, but not while food is lacking or poor. Food has won wars. The lack of it has forced the surrender of great armies. All the way back through history there may be seen the hand of Destiny guiding one army on to victory and another to destruction by the aid of no other weapon than the kind and quantity of food in the commissaries of struggling armies.

In the industrial development of a nation as in warfare, well nourished workers excel. That nation becomes a leader in world affairs whose food supply is sufficient and of a quality to make its people individually healthy and strong. There is a realization of this potentiality in the minds of school authorities when they provide economical noon-day lunches for pupils. It is the same idea that employers and business executives have before them in establishing company lunchrooms and cafeterias for their working forces.

The workingman and the hard pressed housewife in the laboring man's home, who perhaps has the responsibility for the care of a large family, are not always correct in their judgment of food values. Does the wife always fill her husband's lunch pail with the food which is most nourishing? The sandwiches in the dinner pail do not always meet the requirements of the hungry worker. He does not derive from his cold lunch the amount of energy which he needs to replenish his store of physical vigor and keep him fit for the afternoon's tasks. A well prepared lunch of foods selected for their nutritive qualities will actually increase the worker's

output for the day. Dietitians in the employ of large corporations have demonstrated the actual net results of improvement in the feeding of employees and their families.

The corporations that have been most thorough in their studies of food in relation to work and output carry their inquiries into the homes of their workers. Assistance is given to housewives in the selection and preparation of meals which are both economical and nourishing. Thus it is possible to promote better health among large groups of workingmen. In turn the time-loss for sickness and minor illness is reduced, which also effects a reduction of the overhead costs entailed in training new employees or substitutes in the places of skilled men whose services cannot easily be spared.

What the Doctor Wanted To Eat

A well-known physician found time while convalescing from the influenza, last winter, to write us:

"I have taken care of about five hundred cases of influenza in the past six weeks, and came down with the disease myself on the 24th inst. Our cook asked what I wanted to eat, and I said, 'Jell-O and cream every two hours and nothing else.'

"That is the diet I gave my patients, because we have found out that the danger lies in complications, the most fatal being hemorrhage. Now, it is a well-known fact that gelatine in any form helps materially the coagulability of the blood, thereby decreasing the chances of internal hemorrhage."

THE GENESEE PURE FOOD COMPANY, Le Roy, N. Y.

paigns has been recognized as a factor in production. The American workman takes pride in the fact that standards of living in this country place him in a more favorable position than the workingman in a foreign country. He achieves his superiority as a workman because America feeds her population well.

The armies of industry are much like the armies of history. Feed them well, feed them wholesome, pure foods in the right proportion, and their power of achievement has scarce a limit.—*Advertisement.*

MODERN MEDICINE

Incorporating the INTERSTATE MEDICAL JOURNAL.

SUBSCRIPTION

Domestic postage, \$3.00. Foreign postage, \$3.50 (15 shillings). Single copies (regular), 25 cents.

Domestic rates include United States, Cuba, Mexico, Porto Rico, Canal Zone, Hawaii, and Philippines.

SUBSCRIPTIONS.—Subscriptions may begin at any time. Volumes begin January except in the case of Volume I, which consists of the numbers issued during 1919 (May to December, inclusive).

REMITTANCES.—Remittances for subscriptions should be made by check, draft, post office or express money order, or registered letter. Make all checks and money orders payable to MODERN MEDICINE.

CHANGE OF ADDRESS.—Notice of change of subscriber's address should give both old and new addresses. Notice should reach us fifteen days in advance of date of publication.

COMMUNICATIONS.—When communications relate to more than one subject (manuscript, reprints, subscriptions, news items, etc.), correspondents will confer a favor by writing on a separate sheet for each subject, thereby insuring more prompt attention.

ADVERTISEMENTS.—The advertising pages of MODERN MEDICINE are available for announcements of anything of interest and service to those engaged in the treatment and care of the sick and especially to those who are devoting their efforts to organized medical and health work. Advertisements of secret remedies and other objectionable announcements will not be accepted. The supervision of the Editors is extended to the advertising columns, in which only approved products and reliable manufacturers will be represented.

CLOSING OF FORMS.—Advertising forms close on the 10th for the issue of the following month. Ample time should be allowed for composition of advertisements and the sending and return of proofs.

ADVERTISING RATES.—Advertising rates will be sent on request.

CONTRIBUTIONS.—Original articles on any problems of practical interest to our readers are respectfully solicited from those who can write authoritatively on current problems in social medicine, hygiene and medical service in industry, public health and allied subjects. Articles are accepted for publication with the understanding that they are contributed solely to MODERN MEDICINE.

ILLUSTRATIONS.—Such half-tones and zinc etchings as in the judgment of the Editors are necessary to illustrate articles will be furnished when photographs, drawings, or ink tracings are supplied by the author.

NEWS MATTER.—Our readers are requested to send in items of news, and also marked copies of newspapers containing matters of interest. We shall be glad to know the name of the sender in every instance.

BOOKS OF THE MONTH

(Continued from Page 548)

"All tight clothing having been removed, the woman lies down on a level surface. The knees are flexed and to secure perfect relaxation the arms are placed at the side. One hand rests on the abdomen without making any pressure. It is merely to serve as an indicator of the amount of movement. She is directed to see how high she can raise her hand by lifting the abdominal wall and then to see how far the hand will be lowered by the completest contraction of the abdominal walls—drawing in of the abdomen."

"The exercise is repeated ten times. It is carried out twice a day, preferably before dressing in the morning and after undressing in the evening.

"The woman who is not well should study her dress in relation to her body; her habits of eating, water drinking, sleeping, elimination; her exercise and bathing; and make sure she gets sufficient fresh air. . . . If she needs medicine or advice, she should go to the best physician she can find; they never advertise. Finally, she should do these exercises every day in the month, including the days of menstruation, and see if she cannot join the great and growing army of women who are perfectly well, and who recognize that being a woman is not a handicap."

We recommend the hook for general use.

SYMPTOMS OF VISCELAR DISEASE. By Francis Marion Pottenger, A.M., M.D., L.L.D., F.A.C.P., Medical Director, Pottenger Sanitarium for Diseases of the Lungs and Throat, Moravia, Cal.; Professor of Diseases of the Chest, College of Physicians and Surgeons, Medical Department, University of Southern California, Los Angeles, Cal.*

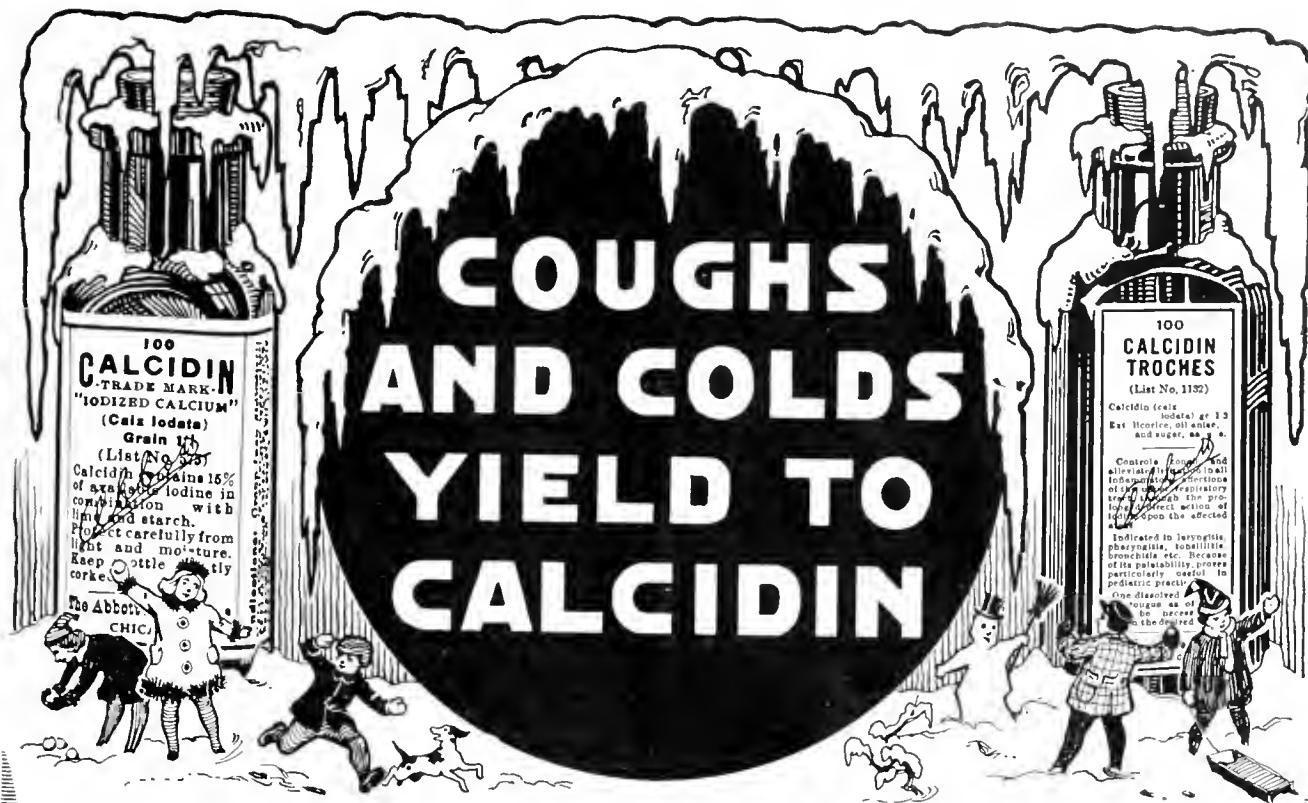

The principal interest in this book lies in an effort to fill the gap of the "uneven development of medicine" lacking in full enough consideration of the patient who has the disease "in the way that such should be presented in clinical aspect of the disease which has the patient."

The effort of the author is a commendable one, and, as far as one can judge at the present status of knowledge, is very well done. There is an explanatory attitude in the opening chapter which the well versed clinician might criticise as unnecessary; this, however, would not be fair to the author when one has knowledge that the average man requires it to awaken his interest in a rather neglected side of practical medicine, although it has been talked about by the older clinicians almost as long as medicine is aged, namely, the consideration of the patient with a disease as well as the disease that affects him.

In the modern development of the laboratory and all means of scientific studies of disease, the patient's reactions against or to the disease have been somewhat lost sight of. In plain language, the work makes a determined effort in this direction, and deserves the support of the serious medical mind in consequence. To the reviewer a doubtful note is struck here and there; but in the study of pathologic physiology or functional pathology there is still so much doubt and irregularity that the reviewer does not desire to mention them in detail. Only continued study in this direction can settle these points and they are insignificant to the main theme of the wholesale attention to the subject that the work encompasses.

The author writes in a simple style and handles complex subjects in an easily understandable way. He has

Influenza Warning

Prepare Now for Influenza and Pneumonia Emergencies

Calcidin, Abbott, the Dominant Remedy

Influenza, Grippe, Coughs, Colds, Croup and other fall and winter respiratory diseases yield to Calcidin, Abbott. Thousands of Clinical reports confirm this fact. A successful doctor in Southern Illinois writes, "I treated 983 cases of influenza last fall. I used Calcidin, Abbott, in practically all of these and only lost one case. I attribute my success to Calcidin and have stocked up, should the flu hit us again."

Urge your druggist to stock Calcidin, Abbott, or send your orders direct to our home office or most convenient branch point.

CALCIDIN-ABBOTT

Supplied in tablet form, coated or uncoated, grs. $\frac{1}{3}$, $2\frac{1}{2}$ and 5. In bottles of 100, 500, or 1,000.

Also in powder form in bottles of 1 ounce and in 5-grain capsules, packed 50 to the bottle.

CALCIDIN TROCHES—Calcidin gr. $\frac{1}{3}$ with oil anise, licorice, and sugar. A delightful throat troche for coughs and croup. Bottles of 100, 500, or 1,000.

THE ABBOTT LABORATORIES

All Food Cells Exploded

Puffed Grains are Prof. A. P. Anderson's scientific foods.

The grains are sealed in guns, then rolled for an hour in 550 degrees of heat. Thus the moisture in each food cell is changed to steam.

Then the guns are shot. Over 100 million steam explosions occur in every kernel. All the food cells are blasted. The grains are puffed to bubbles eight times normal size.

The result is whole wheat, whole rice and corn hearts supremely fitted for digestion.

BOOKS OF THE MONTH

(Continued from page 22)

not tried to explain too much nor in that way gone too far with theory and neurological terms. This casually gives one the impression of a series of detached subjects in paragraphs on different organs and physiologic pathologies. One must read the work as a whole for logical connection, although the specialist in any department of medicine would be repaid by perusal of the opening chapters and then what is mentioned in connection with the organ or organs he is particularly interested in.

ULTRA VIOLET RAYS IN MODERN DERMATOLOGY.

Including the Evolution of Artificial Light Rays and Therapeutic Technique. By Ralph Bernstein, M.D., professor of dermatology, Hahnemann Medical College, Philadelphia; clinical chief, Skin Section, Hahnemann Hospital Dispensary.*

The author has outlined in an orderly manner the fundamentals of ultra violet ray therapy, and details the method of procedure in treating various dermatoses. In general the book is helpful to those who are competent to judge for themselves the effect of light therapy; but does not aid one in the discrimination necessary to select cases for which this method of treatment is especially indicated. The reviewer gleans the impression that the author, in spite of his desire not to become over enthusiastic for this mode of treatment, has permitted himself to become too sanguine.

The reviewer likewise is inclined to take issue with the author in the use of the Alpine Sun lamp, especially in the treatment of urticaria.

INSTINCTS IN INDUSTRY. A Study of Working-Class Psychology. By Ordway Tead.[†]

Sufficient attention has not been paid to what the workers are thinking and feeling. The necessity has been recognized of discovering the mental processes and habits of employers as a class, but the fact that modern industry has been organized and developed without a full consideration of the motives and attitudes of its manual workers perhaps accounts for the undercurrents of industrial unrest which come to the surface with increasing frequency.

It is certain that many of the processes of manufacturing are such as offer little stimulus to the workers. They could afford little mental interest in the work itself, nor any vital sense of creativeness, nor pride in the product. Many of the most essential tasks are so onerous and so fraught with monotony that only the mentally handicapped could find any satisfaction in their performance, and nothing but habit or the necessity of earning a living would serve to keep normal individuals engaged in them.

There is perhaps insufficient training in the skilled crafts to afford much of what is termed the "joy of work" but even if the men do know how to do good work, the tendency to use made-to-order material, the division of labor, the speeding up for high production, the insecurity of the tenure of employment, the entire lack of an opportunity for self-expression, all constitute a tremendous repression of human aspiration and desire that is disastrous in industry as it is in any other field of endeavor.

Conditions cannot be righted until we see human nature as it is. "With the instinct of workmanship understood and given guidance and direction, there need be few fears

(Continued from page 24)

for the future of the workers or for the future of workmanship. We have only to understand that there is no true joy in work and no true workmanship apart from an appreciable degree of self-direction and self-control."

Ten basic instincts on which our whole life and conduct rest are analyzed as they affect industry. The study is made with reference to the importance of the individual personality. No attempt is made to elucidate the complex group reactions, but the author outlines the origins of some of the characteristic reactions which form a basis for prediction of behavior under given conditions, and for intelligent direction and control. He concludes that "since adequate expression of individual and group impulses requires a considerable measure of self-direction, it seems not unlikely that the demand for an extension of the democratic method is in fundamental harmony with the facts of human psychology."

TRENCH FEVER. A Louse-Borne Disease, by Major W. Byam, R.A.M.C., Captains J. H. Carroll, U.S.R., J. H. Churchill, R.A.M.C.(T), Lyn Dimond, R.A.M.C., V. E. Sorapure, R.A.M.C., R. M. Wilson, R.A.M.C., and L. Lloyd, R.A.M.C.(T), Entomologist; with an introduction by Lieut. General Sir T. H. Goodwin, K.C.B. A foreword by Major General Sir David Bruce, K.C.B., F.R.S., A.M.S., and a summary of the report of the American Trench Fever Commission by Lieut. R. H. Vercoe, R.A.M.C.*

Major Byam merits great credit for presenting this text to the medical profession. It is very cleverly and convincingly written, covering the subject in a most thorough manner. The chapter on the acute disease depicts in a most lucid manner the six different types of the infection from a clinical standpoint and enables the reader to become acquainted with these types so that he may avoid the early pitfalls that befell the diagnosticians when they first encountered the infection on the Western Front.

Possibly never in the history of medicine has so complete a work on the mode of transmission of a disease been done in such short time as in the investigation and study of Trench Fever. These experiments are minutely though not tediously described, and it greatly facilitates the reader to thoroughly understand the methods of prophylaxis and their essentialness in combating the disease. It is also ably pointed out that there are various types of the disease and not many diseases.

The text is most complete, failing though to point out the parasite, which yet remains to be discovered—a most important factor. However, the chapters on Immunity, Pathology, a very complete clinical description of the chronic disease with its important complications (D. A. H. and Neurasthenia), and Prognosis and Treatment are quite readable and instructive.

The carefully arranged appendices contain most valuable information for the medical man associated with men in camps or living under similar group conditions. This greatly enhances the value of the book, which well deserves a place on the shelves of any medical library.

W. M. LALOR CO., Manufacturers

431 S. Dearborn St., Chicago, Ill.

Every thinking person now acknowledges that Progress in personal, household, and civic hygiene and sanitation has contributed greatly to the health, happiness and long life of Mankind.

AMONG the changes that have resulted from this advanced thought, changes that are touching the daily life and habits of every home and individual, is the doom of the seamy, squeaky wooden bed; the doing away with the double bed wherever possible, and the insistence upon a separate bed for every individual.

Discussion and explanations of the health-building advantages and efficiency, resulting from sound, restful sleep, is an important part of the work of physicians,

welfare workers and visiting nurses everywhere. It is work in which this company is prepared to co-operate. A wealth of data is now available to interested workers in this field. As the largest makers of metal beds in the world we are always glad to supplement the work of others in spreading the gospel of sound, restful sleep.

The requests for data, by Physicians, Public Health Officials, Hospital and Welfare Workers bring prompt response when addressed to our Main Office at Kenosha.

Accurate Diagnosis First

No industrial hospital is complete without the most modern facilities for diagnosis. They must be ever ready for the immediate attention a patient's case demands.

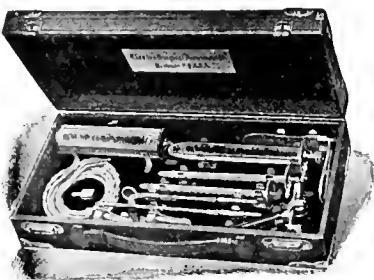

Diagnosis directs the course of treatment and can only be accomplished by the most advanced and approved aids.

For just such attention by the industrial or municipal physician our

MODERN DIAGNOSTIC OUTFIT

is arranged. It contains all the instruments most generally needed in urgent cases.

Others will be substituted if desired. Stamp "E. S. I. CO." is guaranty of our manufacture.

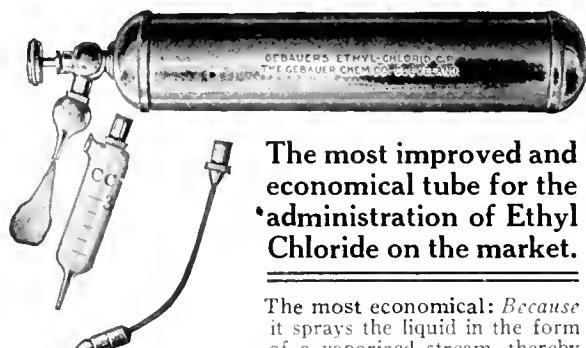

This outfit weighs but 4½ pounds. All instruments can be operated by our battery with adapter or upon direct or alternating current by means of our controller.

Illustrated catalogue sent upon request.

METHODISTS' FORTY-SEVEN HOSPITALS WORTH \$16,000,000

The Methodist churches of the United States now have forty-seven hospitals at which 100,000 patients are cared for annually, exclusive of out-patients, according to the *Christian Advocate*. The property value of these institutions is \$16,000,000. The next quadrennial conference of the Methodists to be held at Des Moines, Ia., in 1920, will consider the advisability of placing the hospitals and related institutions under the control of a board of philanthropies.

MORTALITY FIGURES FOR OHIO

Among the first mortality figures published for the states for the year 1918 are those for the state of Ohio which appears in the *Ohio State Medical Journal* for September. These figures throw much light on the extent of influenza and pneumonia through the worst period of the epidemic. The average death rate for 1918 was 17.82 per thousand as against 14.75 per thousand in 1917. There were 11,986 cases of influenza, or 2.84 per thousand, as against 959 cases in 1917. Lobar pneumonia took a total of 9,605, or 1.82 per thousand, against a total of 4,864 cases and a rate of 0.93 per thousand in 1917. No striking differences appear in other forms of disease.

HEALTH OFFICERS' ROUND TABLE

The coordination of public and private health and social agencies in the control of tuberculosis was discussed by health officers from various localities at a health officers' round table held during the seventh session of the Mississippi Valley Conference on Tuberculosis, held at Des Moines, Ia., in September. Another interesting feature of the conference was a symposium on the subject, "Locating Tuberculosis in a Community." Several demonstration clinics were attended and a visit made to the United States army hospital near the city where the work of the Department of Occupational Therapy was inspected. A series of demonstration clinics in early diagnosis of tuberculosis for physicians not specializing in that disease were conducted under the auspices of the Iowa Trudeau Society.

A NEW HEALTH SYSTEM IN ALABAMA

The *Birmingham Ledger* expresses strong approval of the bill for a new state health department, but suggests that more democratic control be placed in the selection of the members of the State Board. The *Ledger* says:

"Alabama is in dire need of a real health system to care for the state along the most progressive sanitary lines. For that reason the *Ledger* favors the bill presented by the state medical society in its general bearings. We cannot trust to luck in such matters as the flu, spread of the social disease and the like. We must have a system with the authority and equipped with the means to conserve health and prevent disease."

"The *Ledger* has no fault to find with the bill other than the autocratic character of administration. This, it is understood, has been partially waived by an amendment adding the governor to the state health board and conferring powers to confirm local health boards on local officials elected by the people. The concession does not go deep enough. The physicians would still name the health boards, who name the health officers.

"The general assembly should go to the enactment of this health bill with the dual thought of preserving its general features and, at the same time, making the administration more democratic. The bill with an added touch of democracy should pass."

CHEWING GUM IN THE HOSPITAL

TO our sick and wounded boys of the A. E. F. chewing gum often proved a real blessing. As a means of "steadyng the nerves" during painful dressings; to prevent the distressing mouth and throat dryness after "gassing"; to relieve the nervous irritability of "shell shock"; and after operations to avoid the distressing thirst and nausea from the anesthetic, its practical value was repeatedly demonstrated.

The foregoing have taught their lesson, and in many an American hospital today chewing gum is being used as a routine procedure after general anesthesia to allay thirst and nausea. In the fever wards it is being employed in the regular care of patients suffering from typhoid fever, measles, scarlet fever, and other febrile disorders to keep the mouth in a moist and hygienic condition.

In every day practice chewing gum is no less useful, particularly as a pleasant, convenient and exceptionally effective means of relieving certain forms of indigestion, sore throat, nervous cough, for controlling various nervous conditions, cleansing the mouth and preserving the teeth.

Adams Pepsin Gum or Adams Black Jack is the gum most medical men use and recommend, because they appreciate its quality, composition and delightful character.

Ariston Super-Quality Vanilla Flavoring Extract

Ariston Vanilla Extract is made from vanilla beans of the finest quality, in a well-equipped laboratory of scrupulous cleanliness, under personal direction of an expert chemist, and is of truly super-quality.

It is of unusual strength, and therefore gives the very greatest value in both quality and economy.

In its preparation, the choicest beans, as seen above, are first chopped fine by machinery and then put into barrels with alcohol, where they remain in maceration for many months in order that the essence extracted by the alcohol may become rich and mellow in character and delicate in flavor. Finally the liquid is drawn off and drips through percolators, as seen in laboratory view, so that when the extract is bottled it is clear as a crystal and of deep, rich color.

“DEALERS DIRECT WITH YOU”

THE NURSE AND THE CAMPAIGN AGAINST CANCER

The American Society for the Control of Cancer published in July some campaign notes especially directed to the nurses and nursing associations, asking for cooperation in the fight against cancer. Resolutions on the subject have already been passed by the American Nurses' Association, the National League for Nursing Education, and the National Organization for Public Health Nursing. The first two associations urge the teaching of the subject in training schools for nurses. The last named organization emphasized particularly the necessity of dissemination of information concerning cancer.

EIGHTH ANNUAL SAFETY CONGRESS

An entire general session and two sectional meetings of the Eighth Annual Safety Congress of the National Safety Council, which was held at Cleveland, O., October 1 to 4, inclusive, were devoted to discussions of health service in connection with organized accident prevention work.

The program of the congress exhibits lists 160 speakers, including some of the men most prominent in the practice of industrial medicine. It is expected that more than 3,000 safety engineers, industrial physicians, plant managers and others interested or actively engaged in the work of accident prevention will attend the congress.

Dr. Charles A. Lauffer, medical director of the Westinghouse Electric and Manufacturing Company, presided at the General Health Session on the afternoon of October 3 in the ballroom of the Hotel Statler at Cleveland, and at the Health Section meetings during the mornings of October 3 and 4.

While not generally known it is a fact that during the nineteen months of our participation in the war with Germany the casualties from accidents in peaceful America were more than twice as great as the casualties among the American troops in France. The statistics of the United States Census show that more than 70,000 persons died each year as the result of accidents in America. It is estimated that 20,000 of these deaths are caused by industrial accidents and 50,000 by accidents in the streets and homes.

It has been the experience of men and women engaged in organized accident prevention work that a large number of the deaths attributed to accidents result only indirectly from accidents and more directly from causes that can be eliminated by health education. The National Safety Council and the 3,800 industrial concerns included in its membership are therefore giving more and more attention to health education and health service in the war on accidents.

Addresses and papers on health and medical aspects of the safety campaign which will be of interest to physicians and public health officers include the following:

“Physical Examination, First Aid, and Care of the Injured at Cement Plants,” Charles E. Coleman, M.D., Cement Section.

“Lead Poisoning and Its Prevention,” C. P. Tolman, New York City; Chemical Section.

“Humanizing a Steel Plant,” Philip Strommel, Granite City, Ill.; Metals Section.

A number of the leading papers on medical problems of industry will be presented in the November and December issues of MODERN MEDICINE. Among those which will be published are the following:

Industrial Health Hazards; Dr. C. A. Lauffer, Medical Director, Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa.

SCIENTIFIC—EFFICIENT ECONOMICAL

Pain Relieving Methods

You appreciate the value of sunlight as a therapeutic agency; you know about the pure white rays, the violet rays and the ruby screen. The Sterling Therapeutic Lamp combines all these agencies in an efficient and economical manner.

STERLING THERAPEUTIC LAMP

"The Light That Heals"

Has proved one of the most efficient methods of relieving pain; its effect is soothing and analgesic; its rays are germicidal. The warm, soothing, soft rays penetrate and vitalize every cell and tissue, new cell growth is stimulated; the body is refreshed and vitalized.

In rheumatism, neuralgia, neuritis, lumbago, in nervous conditions and a score of other symptoms and diseases, including skin and scalp disease, the Sterling Therapeutic Lamp is invaluable for the relief from pain, inflammation and for corrective purposes.

With stand it is ideally adapted for additional use as a spot light for operations and examinations.

Widely used in sanitariums, physicians' offices and hospitals; special sizes are adapted for the use of patients under the supervision and direction of the family physician.

Write for our interesting Illustrated Booklet showing the various sizes and uses of the Sterling Therapeutic Lamp.

Following the morning session of the Health Service Section on Friday, October 3, a general session was held in the afternoon with "Health" as the subject of discussion, Dr. Lauffer presiding as chairman.

INFLUENZA FATALITIES EXCEED BATTLE CASUALTIES 10 TO 1

The rate of mortality which American life insurance companies had to meet in 1918 was about 32 per cent greater than in 1917, and 14 per cent higher than the average death rate for a score of years.

This is the statement in a summary made public by the insurance press, reviewing the life insurance distributions last year by insurance organizations operating in the United States and Canada, including the transactions of the bureau of war risk insurance.

Ten persons died from influenza for each American soldier killed in battle, the report declares, placing the number of influenza deaths at a half million.

Stating that influenza was mainly responsible for the increase in the number of deaths, the report continues: "Thirty-eight life insurance companies paid \$93,000,000 more than in 1917 for death claims and endowments. The increase in death losses paid by legal reserve companies was approximately \$123,000,000 in the United States and Canada, on lives under the age of 50."

The Insurance press confirms a report of the Connecticut Insurance Company that war claims, meaning all deaths suffered by men in the service not including influenza were equivalent to about a 6 per cent increase over normal mortality. On that basis the war losses by life insurance companies of the United States in 1918 amounted to \$23,000,000.

War mortality, it is stated, will continue in a decreasing proportion for from five to ten years, inasmuch as wounds, diseases contracted, effects of poison gas, shell shock, etc., will impair many lives.

Tuberculosis, it was said, was the basis of nearly 50 per cent of all claims by one company, under the total disability provision of its policies while only 4 per cent resulted from accidents.

Influenza Prophylaxis

AVACCINE prepared from the bacteria which were found to be the chief infecting agents of influenzal pneumonia should afford the greatest degree of protection against influenza and its complications.

All the cultures used in the preparation of **Influenza Prophylactic Lederle** were isolated from cases of influenza in the recent pandemic. They include the influenza bacillus of Pfeiffer; the four types of Streptococcus hemolyticus as classified by Dochez, Avery and Lancefield; the Rosenow strain of Streptococcus viridans, and the Mathers coccus and other green-producing streptococci isolated at Camp Meade; also the three fixed types of pneumococci as originally classified by Cele.

The complete prophylactic treatment consists of three doses injected subcutaneously. The interval between injections is preferably five days, but shorter or longer periods may be used.

	1st Dose	2nd and 3rd Dose
B. Influenzae	500 Million	1000 Million
Streptococcus hemolyticus	500 "	1000 "

Sustaining, Invigorating, Partially Predigested

Borden's Malted Milk offers the tissue-building and invigorating nutrition of clean, wholesome milk and sustaining cereals in a partially predigested form.

These invaluable ingredients are combined by an exclusive process of preparation whereby malt ferments acting on the proteins convert them to partial peptones.

This partial predigestion makes Borden's Malted Milk unequalled as a tonic-food for convalescents, dyspeptics and aged people. It supplies maximum nourishment with a minimum strain on the gastro-intestinal tract.

Samples, analysis and literature on request.

THE IMPROVED
MALTED MILK

RED CROSS NUTRITION LABORATORIES

Perhaps in no other field of welfare work is the need so great nor the results to be achieved more important than the wide dissemination of the knowledge obtained of the nutrition laboratories of the country, and its application to the correction of the unthinkable conditions of poor hygiene, sanitation, and nutriton that prevail in practically every part of the country.

Without proper and adequate food children cannot grow strong in mind and in body, nor can adults be well and do effective work unless properly nourished. Many diseases, such as beriberi, scurvy, pellagra, etc., may be cured by proper feeding. The subject of foods and nutrition is equally as important as hygiene, sanitation, or physical training, and the need of supervision and special instruction in dietaries prescribed by physicians has been no small factor in promoting the hospital social worker, and the work of such agencies as the instructing visiting housekeeper.

But help from time to time from outside agencies is but a temporary makeshift in meeting the situation. Only a small percentage of the housewives of this nation, upon whom lies the responsibility of the feeding of the family, have ever received any instruction in this subject. To supply the crying need of such instruction, the Red Cross has planned an elementary course in Home Dietetics for women.

Scientifically trained women, nutritional experts, and dietitians must stand ready to spread this information. The American Red Cross makes an earnest appeal to those women who are competent to teach dietetics, and to those institutions equipped with class rooms suitable for the use of such classes, for help in promoting this work. Dietitians desiring to instruct classes in home dietetics must enroll in the Red Cross Dietitian Service.

The course in home dietetics as outlined deals with elementary principles; it shows the comparative value of foods; the necessity for a well-balanced diet for adult and child, sick or well; and points out the practical application of the underlying principles of dietetics to buying, cooking and serving food in the home.

The outline of the course is as follows: Planning the day's food; food and what it does for us; vegetables and fruits; the body's need for protein; milk, the indispensable food; meat, fish and eggs; cereals, the best return for your money; bread; sugar and sweets; fats; beverages and food accessories; buying and checking up the food supply; infant feeding; children's food; special feeding.

The course will include lectures and discussions on foods and nutrition; home work, demonstrations, exhibitions, references, and general bibliography. Supplementary posters or pictures accompanying each lesson which may be used as illustrative material in the class room. If a teaching center desires to give individual practice in cookery to a class, the course may be expanded to include this; or demonstrations, exhibitions, etc., may be changed to practical class work.

Vetoes Pennsylvania Mosquito Act

On the ground that the measure recently adopted by the Legislature of the State of Pennsylvania will not rid the state of the breeding places which produce mosquitoes, Governor Sproul has vetoed the act. Through a typographical error of omission, a misstatement occurred in a previous issue of MODERN MEDICINE regarding the vetoing of this measure.

Oklahoma Public Health Meeting

The second annual Oklahoma State Public Health Conference was held in Oklahoma City, September 23 and 24, under the auspices of the Oklahoma Tuberculosis Association and the State Department of Health.

INVESTIGATION OF THE WORKMEN'S COMPENSATION FUND OF OHIO

In 1913 the state of Ohio created a monopoly of workmen's compensation insurance in a state fund in which all employees except self-insurers were compelled to be insured. This fund has been the target for much criticism from opponents of state funds. It was claimed loosely that the fund was insolvent, and there was general mismanagement. Acting upon the request of the Ohio Federation of Labor, the Ohio Manufacturers' Association and the state Auditor, a comprehensive survey was conducted by expert actuaries and statisticians. The *Ohio Medical Journal* remarks as follows:

"The outstanding result of the investigation is that the state fund is and has at all times been strong and solvent, and that it has been conducted with 'economy unprecedented even in state funds the world over and at about one-twentieth the expense in insurance companies conducted for profit.' The Ohio fund, measured by the actual volume of benefits insured, has now become the largest carrier of compensation insurance in this country. The fact that the fund has attained this commanding position in volume of business and in financial strength is considered by the auditors as convincing proof of wise and conservative management.

"Aside from its judicious management of financial matters, the Commission has manifested every disposition to deal fairly and even liberally with injured claimants, the report shows. Careful scrutiny of several thousand claim records failed to disclose any evidence of denial of claims by the commission on technical or overstrained grounds.

"A like spirit has been manifested in the medical follow-up of accident cases, the records of serious injuries especially containing detailed medical reports. In a large proportion of cases the records revealed expensive operative procedure and prolonged hospital care.

"The Commission was commended for its recent action in rescinding the ruling requiring advance authorization before the sum of \$200 could be expended in the care of any particular case for medical, hospital, and nursing service.

"The only operative defect is declared to be the delay in handling claims, and this is attributed to the totally inadequate appropriations for carrying on the work and ritualistic procedure required for establishing claims.

"Recommendation is made that a careful budget of financial requirements be prepared and submitted to the legislature, accompanied by data revealing in what regards work is delayed or service skimped by reason of 'too relentless economy.' An adequate appropriation would permit the employment of a larger staff and a more or less general increase in salaries.

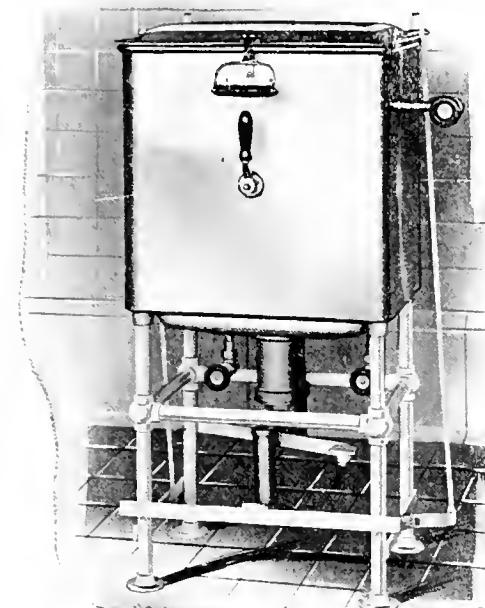

"These recommendations coincide with the position which the Association has persistently maintained: That a sufficiently large force in the medical department, adequately compensated, would not only insure prompt and efficient handling of workmen's compensation cases, but would facilitate the dealings of the profession with the Commission. "The claims division has a total of ninety-

(Continued on page 38)

"AMERICAN"

THE PRODUCT OF SPECIALISTS

BUILDINGS versus EQUIPMENT

Bed-Pan Sterilizer and Washer
Dumping Type

The reputation of an institution does not depend so much upon the character of the buildings that house it as upon its PERSONNEL and its WORKING EQUIPMENT.

Beyond a certain point anything that may be added to the exterior becomes an embellishment—beautiful but not VITAL.

Proper sterilizing equipment is vital.

Next in importance to the human element in any undertaking are man's mechanical aids. Doubly so is this true of the Surgeon's work.

"AMERICAN" sterilizers are built to be worthy of this important role. DEPENDABLE, EFFICIENT and EASY OF OPERATION—they have gained the front and have kept it.

The "AMERICAN" Bed-Pan Sterilizer and Washer, as illustrated, easily proved to be the most popular sterilizer shown at the Cincinnati Hospital Superintendents' Convention.

AMERICAN STERILIZER COMPANY, Erie, Pa.

COLLECT SOILED LINENS
IN THE EFFICIENT, ECONOMICAL
AND SANITARY WAY

The Solar Self-closing Waste Can

The inside sack, when filled, is lifted out and replaced with an empty one. The filled sack and contents are carried to the laundry. The collector is always in service—removals are prompt and complete.

INVESTIGATE COMPENSATION FUND

(Continued from page 36)

three full-time employees, including seven field investigators, to handle an annual volume of over 150,000 claims. 'There is crying need of more and better paid deputies, referees, medical examiners, and field investigators, to establish prompt touch with beneficiaries and facilitate the hearing of claims,' the report says.

"The salaries are miserably insufficient to attract and retain capable men for the responsible positions. Medical examiners receive from \$2,000 to \$3,500 per annum. The director of claims receives only \$2,400 for directing the claims department which has the immense premium income of \$1,000,000 per month.

"Regarding the obligation of the state to pay higher salaries to the men who are primarily responsible for the determination of claims, and to vest them with larger discretion, Mr. Downey says: 'It is physically impossible that the Commission should actually pass upon more than a minute fraction of compensation claims. In the vast majority of cases, the decision of the claim examiners in the office or of the claim investigator in the field, of the medical examiner, the referee, or at most the director of claims will become in effect the decision of the Commission. If these men, in their several ascending grades, possess the requisite training and experience and are vested with appropriate discretion, the procedure will take on a character of flexibility and dispatch.'

"At present the Commission requires, as a basis for establishing a claim, a formal application from the claimant, supported by the employer's report of accident and by a medical report. Failure to receive any of these documents means delay. In the following statement, in which dilatory doctors receive their share of censure, the auditors are frank to discredit his 'red tape' procedure and suggest its curtailment: 'Application from the claimant is required upon purely legalistic grounds. . . . In most cases, indeed, the application is a matter of form, the blank being filled out and the applicant's signature secured by the employer himself. But the employer is sometimes averse to the payment of compensation and the injured man is often ignorant of his rights or incapacitated by his injury from filing a claim. The medical report, again, is required to establish the fact of disability. This requirement is the more reasonable in that practically every compensable accident requires medical attention. Medical men, however, are notoriously negligent in the making of reports. To withhold compensation for weeks or months pending the report of the attending physician is to inflict unmerited hardship, not upon the delinquent doctor, but upon his hapless patient. Numerous instances were found of such delay in cases where no medical report was filed to establish the fact of disability. It needs no expert testimony to prove that a man with a broken leg will be disabled for several months or that a coal miner "caught by a fall of slate" has sustained compensable injury. The remedy is neither far to seek nor difficult to apply. The employer's notice of accident is, or can readily be made, *prima facie* evidence of a compensable accident.'

"Among other suggestions for extension work which would be possible under an adequate appropriation Messrs. Downey and Dawson recommend the careful compilation for future reference of statistics accumulated under the Workmen's Compensation Act, and reinforcement of the accident prevention work undertaken by the Commission in an effort to reduce the number and seriousness of industrial accidents."

Cafeterias and Rest Rooms *are* Common Sense Health Insurance

The physical and mental well-being of employees are important factors in the efficiency of every industry.

Faulty nutrition is recognized as a detrimental condition for the satisfactory progress of school children as well as preventing 100 per cent service from the employee.

Properly conducted cafeterias have proved their worth in bringing the individual up to par in both industries and schools.

Rest and club rooms, considered essential by many employers, add that element of good will necessary for the complete co-operation of the employee.

The experts of Albert Pick & Company have made an exhaustive study of these and similar conditions and the results of this survey will be gladly forwarded to anyone interested.

Write for our special literature as follows:

Book G10—Lunch Room Book—containing complete data on industrial lunch room installations.

Book G40—Rest Room Book—The whole story of the rest room.

Book G60—Employment Betterment—The story of what industrial welfare work means in actual results.

ALBERT PICK & COMPANY

208-224 W. Randolph St.

Chicago, Illinois

Basic Principles Embodied in the Construction and Design of the New York Study Chair

First—A movable seat and desk in one unit.

Second—A seat modeled to the normal shape of the thighs and buttocks, allowing thereby the pelvis to rest on the normal weight-bearing surface of the tubera ischii, and thus avoiding forward slipping of the pelvis with its forward rim tilting upward and consequent distortion of the spine.

Third—A seat adjustable to height.

Fourth—A back so formed as to allow the occupant to maintain the torso in the normal erect position.

Fifth—A movable back support, convex forward, that will maintain the normal forward lumbar curve and compel an erect position of the entire spine.

Sixth—A back of proper height with a top cross bar to prevent round shoulders.

Seventh—A desk that can be easily adjusted to any desired position, height or angle for drawing, reading or writing.

Eighth—A back, seat and desk, so correlated as to give a correct and yet comfortable "set-up" to the occupant when at work.

180 MEN OF THE A. E. F. BLINDED

Latest reports give the number of American soldiers of the A. E. F. blinded in the war to be 180. Re-education means much for this class of men, and about one-third of these blinded soldiers are now availing themselves of the opportunities for training under the direction of the Federal Board for Vocational Education.

Poultry raising has been tested and proved to be a lucrative vocation for blinded men. With the assistance of members of their families these blinded soldiers are making good at it. Osteopathy and massage are attracting others as occupations desirable for the blind.

The policy of the Board in building upon the past experiences of disabled soldiers in fitting them for future employment is adhered to in its dealings with the blinded. In following this policy, an insurance man and a druggist are training in their old lines of work, learning to "carry on" in the old way in spite of their handicaps.

BOOKS RECEIVED

[Comment on current medical and health literature will be found on page 548, in the department, "Books of the Month."]

THE HOUSING OF THE UNSKILLED WAGE EARNER. America's Next Problem. By Edith Elmer Wood. Cloth, 12mo, pp. 321, \$2.25. The Macmillan Co., New York, 1919.

EMPLOYMENT PSYCHOLOGY. The Application of Scientific Methods to the Selection, Training, and Grading of Employees. By Henry C. Link, Ph.D., Cloth, 12mo, pp. 440, \$2.50. The Macmillan Co., New York, 1919.

NERVE CONTROL AND HOW TO GAIN IT. By H. Addington Bruce. Author of "The Riddle of Personality," "Handicaps of Childhood," etc. Cloth, 12mo, pp. 307, 4th Ed. Funk & Wagnalls Co., New York, 1919, \$1.00.

MILK. By Paul G. Heinsman, Ph.D., director of the laboratories of the United States Standard Serum Co., Woodworth, Kenosha County, Wis. Cloth, 8vo, pp. 684, 237 illustrations, \$6.00. W. B. Saunders Co., Phila., 1919.

ANIMAL PARASITES AND HUMAN DISEASE. By Asa C. Chandler, M.S., Ph.D., instructor in zoology, Oregon Agricultural College, Corvallis, Ore. Cloth, 8vo, pp. 570, illustrated, \$4.50. John Wiley & Sons, Inc., New York, 1918.

THE HEALTH OFFICER. By Frank Overton, A.M., M.D., D.P.H., sanitary supervisor, New York State Department of Health, and Willard J. Denno, A.B., M.D., D.P.H., medical director of the Standard Oil Co.; formerly secretary of the New York State Department of Health. Cloth, 8vo, pp. 512, 51 illustrations, \$4.50. W. B. Saunders Co., Phila., 1919.

AIR, WATER, AND FOOD FROM A SANITARY STANDPOINT. By Alpheus G. Woodman, associate professor of food analysis, and John F. Norton, associate professor of chemistry and sanitation, Massachusetts Institute of Technology. Cloth, 8vo, fourth edition revised and rewritten, pp. 248, illustrated, \$2.00. John Wiley & Sons, Inc., New York, 1919.

DISEASE OF THE HEART. Their Diagnosis, Prognosis, and Treatment by Modern Methods. With a Chapter on the Electrocardiograph. By Frederick W. Price, M.D., F.R.S. (Edin.), physician to the Great Northern Central Hospital; assistant physician to the National Hospital for Diseases of the Heart, London. Cloth, 8vo, pp. 472, illustrated. Oxford University Press, New York, 1918.

INDUSTRIAL NURSING. For Industrial, Public Health, and Pupil Nurses, and for Employers of Labor. By Florence Swift Wright, R.N., Bureau of Child Hygiene, New Jersey State Department of Health; formerly secretary of the benefit association of the employees of John Wanamaker, New York; and formerly in charge of industrial nursing for both the Cheney Brothers' Silk Mills and the Clark Thread Company. Cloth, 12mo, pp. 179. The Macmillan Co., New York, 1919.

NOTES AND COMMENT

THE FALL CONVENTIONS

THE months of September and October have been especially productive this year in medical literature in the form of papers read at annual conventions. Beginning with the American Hospital Association and Allied Associations, there were several conventions held in quick succession. The International Association of Accident Boards and Commissions directed a large part of its program to industrial medicine. The National Safety Council directed one general meeting and two sectional meetings to industrial health. The Clinical Congress of Surgeons and the American College of Surgeons gave the usual strong program, and the American Public Health Association finished up the month of October with a broad program of public, industrial, and social health. There were also large numbers of state and sectional meetings of industrial, public health, and industrial bodies.

These conventions following close upon each other with the discussions of similar problems in each suggest the need for a better correlation of effort and a coordination, at least in time and place, so that the energy now expended in travel might be conserved for the purposes of the conventions. Industrial and public health officials could not afford to miss any one of the conventions held in September and October, and yet on account of distances very few could afford to go.

With the conventions ended, forward-looking men and women are turning their attention now to the furtherance of the plans and work which have been under discussion. The conventions of next year should disclose the practical good that is to spring from this season's meetings.

DRY ENFORCEMENT AND PATENT MEDICINES

THE report of the legislative committee of the American Hospital Association calls attention sharply to the evident influence of patent medicine forces in framing the dry enforcement laws of states and the nation. Their statement follows:

"What have patent medicines to do with dry enforcement bills and hospitals?

"In the May number of MODERN MEDICINE, Dr. S. S. Goldwater has an article on 'The Care of the Sick in the United States in 1919.' He outlines the need of a medical program, and points out that the United States is a great nation suffering, among other things, from patent medicines. There are \$900,000,000 invested in patent medicines in the United States. With the adoption of the national prohibition enforcement laws, it looked for a time as if the patent medicine industry, which hospital people in general contend has been a great menace to public health, might be driven out of existence, and some of the sufferings of the nation eliminated thereby.

"This much desired result may not come to pass. In one state at least which has adopted state prohibition, the dry enforcement bill was written in the special interests of the patent medicine manufacturers to the detriment of public health. A repetition is possible in Congress; at least, it is possible that the national dry enforcement act may be so modified as to permit the patent medicine industry to continue, when, as all hospital people know, it should be killed, not injured. Are the seven thousand hospitals in the United States going to sit back and do nothing about it, or will

those represented at this convention give some instructions to their legislative committee? A communication direct from the convention to the Senate committee on this subject is suggested.

"When the next state legislatures meet, however, to write new dry enforcement laws, let the hospital and health workers beware. Many times will your help be needed in deciding legislative contests—patent medicines *vs.* public health."

The friends of prohibition might well be on their guard to prevent the results feared by the Association. They cannot afford to have the prohibition movement burdened with the patent medicine octopus, or to have the slightest suggestion of a willingness on their part to compromise with the patent medicine evil.

VITAL STATISTICS AND THE PHYSICIAN

CONDEMNATION of statistics is often heard and complaint is often made by physicians against the burdens imposed upon them in reporting facts of births, deaths, and diseases. These come from a misunderstanding of the value of statistics, both to the state and to the physician.

There is a stale joke constantly repeated that "Statistics lie and statisticians are liars." Many take this as the final condemnation of all statisticians and all statistics. The results are unfortunate.

The facts are that some statisticians may be liars, just as some members of other professions; but, it is the man who lies and not the statistician. Statistics may be made to lie, but so may words be made to lie. We do not condemn the English language because untruthful people combine words so as to tell an untruth. Statistics, in the hands of incompetent or immature statisticians, may be wrongly interpreted, but so may the facts in diagnosis of physical or social ills be misinterpreted. Given a statistician who knows his business and statistics which are carefully collected facts, the result will be an unerring interpretation. So unerring are such interpretations that the great business of insurance is built securely on the foundation of statistics, while practically all great business is grounded in one way or another on the interpretation of these basic facts.

The primary interest which the physician has in vital statistics is pointed out in this issue by Prof. George Chandler Whipple, of Harvard University. Vital statistics is regarded by the author as so important to the physician that he recommends that the subject be placed in the curriculum of the public health and pre-medical

schools. Elsewhere the same author has pointed out the national value of vital statistics.

"It is of the greatest importance to a nation that accurate records be kept of its vital capital, of its gains by births and immigration and of its losses by death and emigration; for a nation's true wealth lies, not in its lands and waters, not in its forests and mines, not in its flocks and herds, not in its dollars, but in its healthy and happy men, women, and children. A well man is worth more to a nation than a sick man; a man in the prime of life is of more immediate worth than an old man or a child; a married man is potentially a greater asset than a single man. Hence, in a nation's vital bookkeeping the number of people, their age and sex and conjugal condition, their parentage, their health, the rate of births and deaths, are matters of great moment. Their environment is also important; their concentration in cities and villages and congested areas, their mode of housing, their occupation, their state of intelligence, their economic condition, their knowledge of sanitation—all contribute to the sum total of their usefulness to themselves and to society.

"Vital statistics are useful for many purposes. To the historian they show the nation's growth and mark the flood and ebb of physical life; to the economist they indicate the number and distribution of the producers and consumers of wealth; to the sanitarian they measure the people's health and reflect the hygienic conditions of the environment; to the sociologist they show many things relating to human beings in their relation one with another."

The public health officer who senses deeply the responsibility that is entrusted to him knows that he must study diligently the statistics of morbidity from his own and other districts at all times if he is to perform his public function wisely and well.

CORRECTING SOME ERRONEOUS IDEAS ON TEMPERATURE AND HUMIDITY

IN this issue of Modern Medicine there appears the third of a series of articles by Ellsworth Huntington, of Yale University, on temperature and humidity in their relation to health. These articles, together with the author's work as published in "Climate and Civilization," form a distinct contribution to the scientific discussion of the subject and offset some of the pre-conceived notions regarding the bearings upon health of temperature and humidity.

Applying these principles to everyday life and the care of the sick, we present herewith a summary of the conclusions presented by Doctor

Huntington as they relate to hospitals and to the control of air conditions in sick rooms.

In determining the kind of air best adapted to sick-rooms there has been confusion along several far-reaching lines. The first is confusion between temperature and humidity. People feel cold on a zero day even with the thermometer at 70° F. indoors, whereas on an autumn day with a temperature of 65° they often sit beside the open window and feel perfectly comfortable. The reason is that the winter air, when heated, has a relative humidity of perhaps 15 per cent, and evaporation from the skin is so rapid that it is almost impossible to keep warm. The autumn day, on the contrary, has a relative humidity of perhaps 75 per cent. Hence there is little evaporation, and the skin feels warm and comfortable.

A second line of confusion relates to humidity alone without reference to temperature. At all seasons people are apt to confuse the effect of humidity in the air and of moisture condensed on the clothing or skin. The water vapor in the air, which is imperceptible to sight or touch except that it makes the air feel "soft," is usually beneficial except at high temperatures. Condensed water vapor, on the other hand, whether the water be in the form of droplets of fog, or of a perceptible wetness or clamminess of the clothing, bedding, walls, or skin, is usually harmful because it gives a chilly feeling.

A third line of confusion is between variability of temperature which commonly accompanies direct ventilation, and drafts. Many people recognize that the outside air possesses a most valuable tonic quality, but say that they can not stand even a slight draft blowing in from an open window. The enthusiast for ventilation insists on open windows; the delicate sufferer from colds or from age insists that he, or more often she will catch her death of cold, and so has her way. Both are right, for although outside air is good, most of us have lived so long under artificial conditions that drafts are likely to lead to chills.

In view of these facts the modern hospital physician is confronted by three great necessities. First, he must keep the temperature comparatively low, averaging not far from 65° F., but he must not let it feel cold. Second, for this reason and still more because moist air is good for the human system, he must install a humifying system which will keep the relative humidity up to 50, 60 or even 70 per cent when the temperature is 65°, but which will not be so erratic that condensation will take place. Third, he must regulate the ventilation system so that the temperature of the air will vary frequently and there will be abundant movement, but yet so that there will

be no perceptible drafts. In a previous number we have discussed the first two points, but they may well be urged once more on our readers. The third point needs further discussion.

Recent experiments indicate that our old ideas of ventilation are quite wrong. We do not need ventilation because of the exhaustion of the oxygen in the air, or the accumulation of carbon dioxide, for even in the Black Hole at Calcutta it is doubtful whether those two processes had gone far enough to kill the British soldiers. Probably one of the chief reasons for ventilation is that certain toxic substances are given off in the breath, and these may act as poisons, thus leading to discomfort, sickness, and finally death, although this is not yet certain. Constant, though slow movement of the air is probably essential in order to carry away such toxins. There is also another and, under normal conditions, equally important element involved, namely, variability.

Turn for a moment to the outside air. No one doubts its efficacy. In our best hospitals we go to no end of trouble to get our patients out of doors. Why is the outer air so efficacious? And why do we get such poor results when we take the same air and after freeing it from dust carefully pour it into our wards in a full and steady stream? The experiment has been tried time and again, and the result is invariably less satisfactory than ordinary outside air, even when that has to be let in through the windows. When the New York Ventilation Commission tested such an ideal system of ventilation in comparison with window ventilation where the element of drafts was removed, it found that among several thousand children those in the rooms with the "ideal" ventilation had 136 per cent more colds and other minor respiratory diseases than had the others, and 30 per cent more absences due to respiratory diseases. Certainly the freeing of the air from dust cannot cause more colds. Nor can the quantity and movement of air in the two cases make any appreciable difference. Why then so great a difference between outside air and "ideal" inside air?

The answer seems to be variability. Suppose one is living out of doors. On a clear day the temperature changes constantly in its rise from morning to noon or later, and in its fall the rest of the day. Each cloud that sweeps across the sun brings a temporary change of several degrees; each little breeze makes the air feel cooler; you move into the shade or the sun gets around the corner, and again there is a change. Even on a still summer day the number of changes experienced out of doors runs into dozens. If you doubt the stimulus of such changes, which no

sane man does, put your head out of the window some day when your windows all have been shut, and see how much more eagerly you attack your work after a few minutes of outside air.

On the other hand, take a series of days when the temperature remains the same day and night, as it sometimes does in damp weather. The dampness itself may be beneficial, but the total effect is bad.

The measured work on factory operatives shows that they unconsciously work slowly during periods when the temperature remains the same day after day.

Our modern system has been based on the false assumption that uniformity is desirable. We must go back to Nature's ways, for man's evolution during untold millions of years was always outdoors, and so continued for hundreds of thousands of years after he became man instead of beast.

How foolish of us to suppose that we can suddenly change an adaptation which is the fruit of millions of years of evolution. Hence our aim should be to make the air in our hospitals and houses exactly like the best outside air—like that of the pleasant days when we bubble over with joy because spring has come, or of the glorious autumn

SURGEON GENERAL IRELAND HONORED BY FOREIGN SURGEONS

Maj. Gen. MERRITTE W. IRELAND, Surgeon General, M.C., U.S.A.

An honorary fellowship has been conferred upon Major General Merritte W. Ireland, Surgeon General of the United States Army, by the Royal College of Surgeons of Edinburgh, Scotland. This honor, which is paid to but one representative of each group of medical forces of the British Empire and its Allies, is the last of many which have come to this noted American surgeon.

Merritte W. Ireland was born at Columbia City, Ind., May 31, 1867, and is now in his 53rd year. He was graduated from the Detroit College of Medicine in 1890, his graduation being followed by an internship in St. Mary's Hospital, Detroit. He is also a graduate of Jefferson Medical College, Philadelphia. In 1891 he entered the service as first lieutenant and assistant surgeon. During the Spanish-American War, he served with the Fifth Army Corps in Cuba. In 1899, he was promoted to surgeon with the rank of major. Shortly afterward, he went to the Philippine Islands. In 1900 he was honorably discharged from volunteer service. Two years later he entered the office of the Surgeon General and in 1903 was promoted to major and surgeon. He became lieutenant colonel in 1911. He accompanied General Pershing to Mexico as surgeon of the expeditionary forces.

When General Pershing went to France he accompanied him as chief surgeon of the American Expeditionary Forces. The rank of brigadier general was conferred upon him in May, 1918. In October of the same year he was promoted to Surgeon General in the Expeditionary Forces with the rank of Major General.

days when we say the air is like wine.

Of course it is not easy to accomplish all this, but an important step can be taken at slight expense in every hospital at once. That step is to provide the base of every window with a ventilator in the shape of a board or glass so fitted that the window can be opened a few inches without creating a draft. In addition large numbers of screens should be provided so that every patient can be well screened from drafts. Then insist that the nurses open the windows at regular intervals no matter whether the rooms are getting too warm or not.

It is equally necessary besides to insist that the nurses watch the patients with great care to see that none are subject to drafts and that none are chilled. Also the heating apparatus must be so regulated that it responds to the extra call when the rooms are cooled, for the danger of keeping the rooms too cool must of course be avoided. What the patients need is the stimulus of a brief cool spell, like a mild, cold bath, or like a cloud passing over the sun on an autumn day. If such an autumn day is taken as a model, and if the nurses are taught that air is just as important as food, the winter harvest of deaths can be greatly reduced.

VITAL STATISTICS AND THE PRACTISING PHYSICIAN

BY GEORGE C. WHIPPLE, PROFESSOR OF SANITARY ENGINEERING, HARVARD UNIVERSITY, CAMBRIDGE, MASS.; MEMBER OF THE PUBLIC HEALTH COUNCIL, MASSACHUSETTS STATE BOARD OF HEALTH.

OF all the people in the world no class is brought so closely into contact with the vital facts of human existence as physicians,—these vital facts being birth, growth, sickness, and death. In order that physicians may be of greatest service, and practise their calling in the safest and best way, they must be properly educated in medical theory and acquire skill by experience in the hospital and the home. But they must do more than this; they must keep abreast of the times by contact with the work of other physicians, specialists, and scientists in order that they may be ready always to use the best means to a given end. They must also have some way of checking up the results of the methods which they and their associates are using. How can this be done?

Cumulative Experience in Statistics

Experience is the best teacher; and personal experiences make the strongest impressions; but the accumulated experience of many, reinforced by personal experience, is the best of all. A group of doctors meet. One says, "I had a case like this and it progressed thus and ended thus." Another says, "I also had a case like this, etc." And so say several others. Finally, as the facts multiply, some one sums it up and says, "Let us see; how many cases recovered and how many died?" Sooner or later an accumulation of facts has to be expressed by figures; and facts expressed by figures are statistics.

The Powerful Tool of Figures

The world is large today; the medical profession is large. The very largeness of it is making it necessary for physicians to accumulate ideas by studying statistics. No intelligent physician can escape using them. He may think them dry,—and so they are if one does not visualize the facts for which the figures stand,—but he must use them, nevertheless. And now comes the difficulty

THINKING IN LARGER TERMS

If a physician's records are incomplete, or if he draws conclusions not justified by his data, faulty methods and faulty logic, and not statistics, as such, must be incriminated.

If a physician wishes to have his day's work contribute to the sum total of scientific achievement, he must know what statistics are, and what they are not, and must learn to express vital facts in figures.

The process of deduction, the mental habit of analysis, comparison, and appraisal are the logical outgrowth of statistical methods.

need to be made clear and some statistical methods which need to be well understood.

Mature Habits of Critical Study

In teaching vital statistics to classes which included a number of physicians who had been several years out of the medical school and many years away from their study of arithmetic and algebra, it has been interesting to see how at first these older men lagged behind the younger; but how after they had gotten over their first fright and prejudice, they have come to understand the statistical processes as well as, if not better than, the younger men. Perhaps this is because they have a better appreciation of the facts for which the figures stood. I am therefore convinced that physicians would derive not only a benefit but a real pleasure from a cultivation of the habit of studying critically the many statistical investigations found in medical journals and public health reports.

Do Figures Always Lie?

But someone says, "You can't trust statistics; they are so apt to lie." This statement needs explanation. Statistics are facts expressed in figures, and facts are facts. It is possible to misuse facts, so that they will lie; and it is easier to misuse figures when they are divorced from the facts for which they stand. The fault is not with the statistics, but with the logical processes used. An appreciation of the few simple laws of logic will enable one to keep his statistics from playing

—many physicians do not know how to use statistics. They say they never did like mathematics. Perhaps that is why they became physicians instead of engineers. Not liking figures, they tend to ignore them and thus gradually lose one of the powerful tools of their own profession. As a matter of fact, the mathematics used in every-day statistical work is very simple, but there are some statistical terms which

tricks. Logic is none too common in this world. Logic requires the exercise of grey matter, and the easy way out is to say that "statistics lie." When a man says that statistics lie, you may know that he is too lazy to think straight. "Statistics may be used by the unscrupulous to fool the unwary, and by the innocent to fool themselves," but a person who has been taught statistical processes and the elementary laws of logic need not fear the largest array of figures.

The Physician's Responsibility

The first reason, therefore, why physicians should study statistics is for their own self-improvement. The second reason is because many of the most important facts of vital statistics originate with physicians. The laws of our states require that births and deaths be reported to some proper authority, and there are penalties for failure to report. Certain communicable diseases must also be reported as soon as recognized. Physicians as a class are negligent in performing this public duty, and the laws imposing fines for failure to make reports have been imperfectly enforced.

A city clerk gave as a reason for not imposing a just fine on a persistent violator of the law, "Oh, we are too good natured in this office." As a result, the city's birth-records were grossly incomplete,—so obviously incomplete that on the first of each year a house to house canvas had to be made in order to find out how many births really took place in the city during the previous year. There are refreshing signs of a change on the part of the medical profession; and the American Medical Association now has before it the suggestion that failure to comply with the law in regard to reporting shall be deemed to be unprofessional conduct. The real way to secure complete reports, however, is for the physicians themselves to become interested in statistics and realize the part which they themselves play in building up a structure of vital statistics in this country which will be useful to all citizens, but especially to the medical profession.

The third reason is that in the new order of society the practising physicians are likely more and more to assume public functions. Co-operating with the Federal, state, and local health authorities on one side, they come into personal contact with the people on the other. This latter relation has long existed. It is the relation to the health departments which is to be strengthened. The diagnosis of disease and the preparation of various vaccines and antitoxins have already established this relation; the epidemiological investigation of outbreaks of communicable

disease gives another point of contact and the results of these studies are reported in statistical terms. Physicians must know how to contribute the necessary facts for such studies, and how to use the results when presented in statistical form.

An Index of Health Conditions

For many years the general death rate has been used as an index of the health conditions in a community. We now know that this crude death rate, standing alone, means little. The make-up of the population has to be considered, the ages, sex, and nationality of the people, their occupation, their mode of life. We need to study specific rates, and physicians ought to know how to compute them and use them. The process is not difficult. We are more and more talking about life tables. What are they and what do they mean? Life insurance agents must not be allowed to monopolize this field. Biological studies have emphasized the importance of variation. The "average" is not the only, it is often not the best, quantity for generalizing an array of statistics. A knowledge of the ordinary laws of chance or probability is essential to a true understanding of statistics. Indeed, it may be said that an understanding of specific rates and of the theory of probability lies at the foundation of the interpretation of vital statistics.

The ability to take a general death rate and analyze it, to appreciate the statistics necessary to the understanding of the prevention of some particular disease in a community, to use statistics in unraveling the mystery of some epidemic, is a power worth while for a physician to have.

It may be interesting to physicians to know that greater attention is being given to the subject of vital statistics in the schools than formerly. It is one of the required courses in the schools of public health, such as those at Harvard University and the Massachusetts Institute of Technology, Yale University, and Johns Hopkins University. This year for the first time it is offered in Harvard College as one of the pre-medical courses. This is probably a better place for it than in the medical school, for several reasons. The college students are not as far removed from their mathematics as medical students; the course is a broad one which involves principles useful in professions other than medicine and public health; it gives students a bird's eye view of disease classification before studying diseases in detail; it leaves the time in the medical school free for the strictly medical courses.

Looking at the subject in its various aspects, it may be safely asserted that there is a rapidly growing interest in vital statistics in America.

AIR CONTROL AND THE REDUCTION OF THE DEATH RATE AFTER OPERATIONS

ELLSWORTH HUNTINGTON, PH.D., RESEARCH ASSOCIATE IN GEOGRAPHY, YALE UNIVERSITY, NEW HAVEN, CONN.*

Part II. Variability

THE preceding part of this article contains repeated reference to variability as one of the most important elements in the control of the air. We are now ready to discuss the matter in detail. In the first number of MODERN MEDICINE figures were given showing the relation of about 400,000 deaths in New York City during a period of eight years to the weather on the day of death. The figures showed conclusively that when all sorts of ailments are averaged together the general death rate at all seasons varies in close harmony with changes in temperature. In summer and winter alike a drop in temperature is at once followed by a drop in the death rate, while a rise is followed by a rise in the death rate. In the same way, if the temperature from one day to the next remains constant, the death rate on an average also remains constant.

Why the Death Rate Drops with Temperature

That this should be the case in summer is quite to be expected, for everyone knows that hot weather is depressing and that a cool wave is stimulating. But why should it be true in winter? Cold weather is certainly harmful in the long run, as is proved not only by common experience, but by a detailed study of million of deaths. Moreover, sick people who are on the point of death are guarded from the outside air more carefully than any other group. How then can they be at once benefitted by even a slight drop in the outdoor temperature? Elsewhere I have suggested that the case is analogous to a cold bath. The shock of the cold air, like the shock of cold water, is presumably stimulating and has a good effect on health provided it does not last long enough to cause a chill. That explanation may apply to persons who are in good health and who

The idea that uniformity of temperature and of weather is beneficial appears to be wrong. Constant, but not excessive variability appears to be beneficial in almost all diseases, as well as for persons in good health.

In surgical operations this is particularly important. Except in the most extreme weather operations performed when there is much variation from day to day have a far greater chance of success than have those performed when the weather remains the same day after day.

In every hospital and sick room, as much attention should be paid to ventilation as to meals.

came in contact with the outside air often enough to receive its effect, a contact which requires only a few minutes. It does not seem satisfactory, however, for patients who are carefully kept from such contact.

Accordingly, let us inquire by what possible means a drop in the outside temperature can affect the health of patients who are secluded as carefully as possible from every outside in-

fluence. Only two possibilities seem to present themselves. In the first place, changes in temperature are always accompanied by changes in humidity. This fact, as we have already seen, goes far toward explaining why cold weather has so bad an effect on health even when people are kept warm, but it does not help in explaining the stimulus of a cold wave. In fact, it would lead us to expect cold waves to be harmful. Not only is the capacity of cold air for moisture less than that of warm, but, as a rule, the air of cold waves in the eastern United States, with which we are now dealing, contains an unusually small percentage of moisture in proportion to its capacity, for it comes from the dry interior. Since dry air, except at high temperature, is harmful, the conditions of humidity in cold waves would tend to increase, not diminish the death rate.

The second possible means by which cold waves may stimulate sick people is through their effect on the variability of the air. Every one who has cared for a furnace knows that, when the temperature begins to drop out of doors, there is at once difficulty in keeping the house at the uniform temperature which is mistakenly supposed to be ideal. Not only the actual drop in temperature, but the wind which almost always accompanies it causes the temperature indoors

*The second of a series of two articles. Part I was published in the September issue of MODERN MEDICINE.

to fall. Then the furnace draft is opened and, more often than not, the house soon becomes too warm. Next the windows are opened a little, and the temperature falls. So it goes, first this way and then that.

In many houses it is much easier to preserve a uniform temperature on a perfectly quiet day when the temperature stays steadily near zero, or only rises in response to the sun, than on a windy, blustering day when the thermometer falls from 30° one morning to 20° the next morning at the same hour. As a matter of fact, even the houses with the best heating system and the most solid, wind-proof walls are practically certain to be much more variable when the wind is blowing and the outside temperature falling than when the air is quiet and the temperature is either stationary or else gradually rising under the influence of one sunny day after another.

Variability Stimulating and Helpful

In spite of the common prejudice to the contrary, such variability is stimulating and healthful. This does not mean that drafts which cause a chill are desirable. They are merely an incidental feature which is a drawback in so far as people have lived under bad surroundings to such an extent that they have lost their power of resistance. The temperature can vary, however, without causing drafts. The effect of such variations is well illustrated in theaters and other large auditoriums where a change of a few degrees by reason of slowly descending cool air may wake up a dull audience and make it enthusiastic. In temperature, as in many other things, a uniform optimum is not nearly so good as frequent variations in one direction and the other. No one advocates a uniform diet even though it be ideal. If an absolutely ideal meal could be set before people three times a day for a year, does anyone believe that the persons thus fed would be as well as if they had been served with a great variety of good meals no one of which was quite so perfect as the ideal?

It is just the same with the air. We try to have uniformly ideal air in our houses in winter, and thereby we make two grave mistakes. In the first place, as has been pointed out in connection with humidity, we do not actually achieve the ideal, because as yet we scarcely know what conditions of moisture are really right; and in the second place, we try to attain uniformity, which is a mistake. Fortunately, while a cold wave is in progress we rarely succeed in obtaining a uniform temperature, and thus

although the dryness of the wave may do harm this effect is often overcome and reversed by the good effect of the attendant variability.

Now let us turn to operations. Only those which were followed by death after one to ten days are used in Table VII which sums up the whole matter for the Boston City Hospital. For the Massachusetts General Hospital the data are similar, but since our tables for that hospital include deaths more than ten days after the operations they are not included. Table VII shows the deaths per day after operations which were performed when the change of temperature indicated at the top of the table took place between 8 a. m. of the day of operation and 8 a. m. of the succeeding day. The response to changes of temperature is somewhat different in winter and in the remainder of the year, as appears in the two upper portions of the table. For example, from December to February there were 101 days when the temperature fell 9° or more from 8 a. m. to 8 a. m., and the operations performed on these days were followed by 38 deaths, or an average of 0.376 per day. The 52 days with a drop of 4° to 8° account for 19 deaths, or 0.365 per day, and so on until the 99 days with a rise of 9° or more account for 30 deaths or 0.303 per day.

Clearly the death rate after operations in winter is high when the operations were performed at the time of a marked drop of temperature and diminishes systematically as the drop decreases or as its place is taken by a greater and greater rise of temperature. This does not agree with what we have said as to the 400,000 deaths in New York, but this involves no real discrepancy. Patients who are undergoing operations, as we have seen, are peculiarly sensitive to humidity. Cold waves diminish the humidity; moreover, they are usually followed by periods of low temperature and dryness. Thus, although the variability arising from the drop in temperature may be beneficial, the dryness more than counteracts this.

In the next section of Table VII we see that during the rest of the year, from March to November, the death rate is lowest, 0.198, when the temperature drops most rapidly; it increases to

TABLE VII
DEATHS PER DAY AT AN INTERVAL OF 1 TO 10 DAYS AFTER OPERATIONS AT THE BOSTON CITY HOSPITAL PERFORMED ON DAYS WITH VARIOUS CHANGES OF TEMPERATURE FROM 8 A. M. OF THE DAY OF THE OPERATION TO 8 A. M. OF THE NEXT DAY.

	Drop of 9° or more	Drop of 4°-8°	Change of 3° or less	Rise of 4°-8°	Rise of 9° or more
Dec.-Feb.	0.375 (38-101)	0.365 (19-52)	0.326 (31-95)	0.315 (23-73)	0.303 (30-99)
Mar.-Nov.	0.198 (25-126)	0.232 (47-203)	0.343 (201-586)	0.331 (88-266)	0.292 (36-123)
Mar.-May	0.233 (10-43)	0.226 (14-62)	0.495 (105-212)	0.438 (42-96)	0.403 (21-52)
June-Aug.	0.229 (8-35)	0.187 (14-75)	0.293 (65-222)	0.279 (26-93)	0.281 (9-32)
Sept.-Nov.	0.146 (7-48)	0.288 (19-66)	0.204 (31-152)	0.260 (20-77)	0.154 (6-39)

a maximum 0.343, when the change from day to day is at a minimum; and falls again to 0.292 when there is a rise of more than 9°. This same relationship is evident in the shorter seasons into which the rest of the table is divided, although the figures are not quite so regular because of the comparatively limited body of data.

TABLE VIII

DEATHS PER DAY AT BOSTON CITY HOSPITAL AFTER OPERATIONS
PERFORMED UNDER VARIOUS CONDITIONS OF VARIABILITY OF
TEMPERATURE.

	Change of 9° or more in either direction.	Change of 8° in either direction.	Change of less than 3° in either direction.
Dec.-Feb.	0.340 (68-200)	0.336 (42-125)	0.326 (31-95)
Mar.-Nov.	0.245 (61-249)	0.288 (135-469)	0.343 (201-586)

From March to May the contrast between the favorable conditions of falling temperature and the unfavorable conditions of uniform temperature is particularly noticeable. From June to August it is not so striking, although clearly evident. In this section days with a rise of temperature are nearly as bad as those with little change, and would appear worse did not the days of rising temperature include many cases where unusually cool weather is followed by a rise to conditions which are almost ideal as to both temperature and humidity.

In the fall the figures are very systematic, but show a peculiar drop in the death rate at times when there is little change of temperature. This may be due to the fact that in the fall the days that are most nearly ideal as to both temperature and humidity are likely to occur during spells of fairly steady weather. Yet even so, the days with a marked change of more than 9° in either direction average only 0.150 deaths per day against 0.204 when the weather remains uniform.

The Margin of Safety Estimated

Table VII makes the advantage of variability so evident that it scarcely needs further comment. Yet it may be well to add together the days having a given degree of change without reference to whether the weather grows warmer or cooler. This is done in Table VIII. Here it appears that in winter the advantages due to a pronounced drop in temperature do not balance the accompanying dessication of the air. The difference between weather with great changes and that with few changes is slight, however, only 0.014.

During the rest of the year, however, the advantage of variability is great, for the days with a change of 9° or more have

0.098 less deaths than those having a change of less than 3°. To put the matter in another way, the average number of deaths per day from March to November is 0.305. If the conditions all the time could be like those which prevail when the temperature either rises or falls 9° or more, this death rate would be lowered by 19.7 per cent. Here, then, we have still another way in which a change in the air of our hospitals at the time of operations would theoretically produce an improvement of nearly 20 per cent.

In this connection there naturally arises the question whether variability of temperature near the time of death is as important as at the time of the operation. This is answered in Table IX which shows the number of deaths per day when the indicated changes of temperature occurred during the 24 hours preceding and following 8 a. m. of the day of death. In certain respects, the tendencies shown in this table are the opposite of those in Tables VII and VIII. Thus during the winter, especially in section B which shows the actual day of death, rising temperature seems to be harmful, a condition which harmonizes with what has been learned as to deaths from diseases in general.

During the rest of the year, on the other hand, an extreme drop seems generally to be bad. The other figures are indeterminate in Section A of Table IX, but are like those of Table VII in Section B; that is, uniformity is worse than a change. Apparently Section B of Table IX shows a much more genuine relationship than Section A, which is not surprising since B gives the conditions on the very day of death.

On that basis we may say that in winter changes of temperature several days after an operation have a directly opposite effect from changes at the time of operation,—which simply means that at the time of the operation humidity is the most vital factor, while at a later period variability assumes the more important rôle. From March to November, on the other

TABLE IX
DEATHS PER DAY SUCCEEDING OPERATIONS AT BOSTON CITY HOSPITAL, AND
OCCURRING AT TIMES WHEN THE INDICATED CHANGES OF TEMPERATURE TAKE
PLACE FROM 8 A. M. TO 8 A. M.

	Drop of 9° or more	Drop of 8°	Change of less than 3°	Rise of 4° to 8°	Rise of 9° or more
<i>A. Twenty-four hours preceding 8 a. m. of day of death.</i>					
Dec.-Feb.	0.396 (40-101)	0.231 (12-52)	0.327 (31-95)	0.397 (29-73)	0.333 (33-99)
Mar.-Nov.	0.349 (44-126)	0.261 (53-203)	0.319 (187-586)	0.368 (98-266)	0.358 (44-123)
<i>B. Twenty-four hours succeeding 8 a. m. of day of death.</i>					
Dec.-Feb.	0.277 (28-101)	0.307 (16-52)	0.347 (33-95)	0.383 (28-73)	0.404 (40-99)
Mar.-Nov.	0.428 (54-126)	0.266 (54-203)	0.331 (194-586)	0.309 (83-266)	0.301 (37-123)

hand, when extreme dryness like that of winter almost never prevails, variability is desirable at both times although a great drop of temperature may prove harmful. Such variability, however, has less effect at the time of death than at the time of the operation.

It is easy to secure such variability either by open window ventilation with glass reflectors at the bases of the windows to prevent drafts, or else by admitting cool air through ventilators whenever it is needed. This is as important and vital to the patient as the preparation of his diet. The greatest difficulty is likely to be to make nurses and hospital attendants feel the need of being as conscientious in this matter as in the matter of diet.

Another necessity is the avoidance of drafts by the use of screens or other devices, and the careful watching of patients to make sure that they run no risk of getting chilled. If all this were done, and if the suggestions of the first part of this paper were carried out, it seems fair to hope that an extremely powerful and effective agent would be added to the equipment of every hospital and every physician.

In the study of variability even more than of humidity wide cooperation is needed, and the author again asks for as many suggestions as possible.

Summary

With this we must leave the matter. The significant points are:

(1) Variability of temperature is as important as humidity, but its effects are obscured in winter when the extreme aridity of our winter houses is the dominating factor.

(2) Variations of temperature are more important at the time of an operation than at the time of death, although at both times they have a large significance.

(3) Constant attention to variability during the entire time from an operation to the day of discharge from the hospital or sick room would apparently diminish the death rate by at least 20 per cent, in addition to the gain to be derived from proper humidity.

THE LOOKING-GLASS SELF

The physical examinations conducted by way of demonstration before the International Conference of Women Physicians were made before a big triplane mirror. Mirrors have a reputation of being aids to vanity but, properly used, they may have an opposite effect. "Oh, those mirrors are very chastening," says Dr. Eleanor Bertine, Director of the Bureau of Education of the Association. The mirror is also an adjunct in the Health Center gymnasium. After being shown the proper corrective exer-

cises, a girl can see for herself whether she does them correctly. A series of exercises instituted at the Health Center for the correction of minor disturbances of physical health, which really menace both health and efficiency, will be described and illustrated in an early issue of MODERN MEDICINE.

As in other problems of social adjustment, correction is largely a change of attitude. The object of the Bureau of Social Health is to establish certain health standards to show how they may be attained and so to present them as to make them the object of sincere and persistent effort.

RECONSTRUCTION IN FOREIGN COUNTRIES

One method of aiding in reconstruction in Australia is the reservation annually of ten places in two educational institutions for the children of fallen and disabled soldiers, according to *Readjustment and Reconstruction Information*, of the Reconstruction Research Division of the United States Council of National Defense.

The dismissal of disabled employees from factories has been forbidden by the German war office unless other positions have been provided for them. In the United Kingdom any increased charge incurred for compensation for disabled men is to be borne by the State, on the theory that disabled men are more liable to meet with accident in the course of employment, or the results of an accident to be more serious than they would be normally. Under this scheme, the Government enters into an arrangement with the insurance companies whereby the usual rates for a particular occupation are charged which are not increased as the result of the employment of disabled men. The Government, under certain conditions, is to reimburse the loss which the companies may incur.

Contributions to the Ludendorff fund are being solicited in Germany, the money to be used to relieve cases in which the law, on account of its rigidity, could not make sufficient provision. Many sick and internally injured soldiers were discharged without pensions, and are dependents.

The Japanese Government will devote more than \$20,000,000 for higher education within the next six years. More than \$2,000,000 of this will be appropriated to dispatching and maintaining students abroad.

A research board has been appointed by the Department of Scientific and Industrial Research of the United Kingdom and the Medical Research Committee jointly to investigate the hours of labor and other conditions of employment the survey to include methods of work and the production of fatigue, both to be considered as related to industrial efficiency and the preservation of health.

The City of Toronto has appointed a permanent housing commission which will see to the incorporation of a company, the latter to build about 300 houses in various parts of the city which will be for sale at a cost of about \$3,000. This is being done on the theory that the man who buys is more valuable than the man who rents.

The chief of the health service has put before the French Chamber of Deputies a proposed law for the treatment and care of tuberculosis. In support of the measure he stated that France has cared for 55,000 tuberculous soldiers during the war and that there are now at least 500,000 cases in France. These figures are serious in a country which, even before the war, was beset by the problem of depopulation.

The proposed law provides for dispensaries and hospital care whenever necessary, and for pensions to families when the wage worker is in a hospital. The estimated cost is 84,000,000 francs as an initial expenditure, with an additional 100,000,000 francs annually.

THE NATIONAL SAFETY COUNCIL

Through the courtesy of the National Safety Council MODERN MEDICINE is enabled to present in this issue a group of selected papers on medical subjects which were read before the Eighth Annual Congress of the Council, held October 1 to 4, at Cleveland, Ohio.

Below is a statement of what the Council is and what it does.

What the National Safety Council Is

The National Safety Council with headquarters at 168 North Michigan Avenue, Chicago, is now the leading organization in the United States for the prevention of accidents in the industries, the streets, and the homes. Organized in 1913 with forty members, it now has a membership of over 3,700 factories, railroads, insurance companies, technical schools, governmental agencies, etc., employing an aggregate of more than 6,000,000 workers. Its income is derived solely from membership dues. It does its work without asking for profits. It is cooperative, non-political, non-commercial. Practically all the industrial concerns, railroads, and other public utilities, both large and small, which have obtained the best results in accident prevention are members of the National Safety Council.

What the National Safety Council Does

(1) Maintains a bulletin service. Three posters suitable for posting on bulletin boards where the messages of care and caution may come directly under the notice of the workmen are issued each week. One bulletin is issued each week for the executives, bringing to their attention the latest and best plans, methods, and ideas for getting the best results from safety work and from other industrial relations activities.

(2) Maintains an information bureau for answering inquiries on all phases of safety work, sanitation, industrial hygiene, and other branches of industrial relations. The Council also maintains a complete and comprehensive library on safety which is available to its members.

(3) Publishes "Safe Practices Pamphlets" monthly. These engineering studies of industrial hazards are written in plain, everyday English so that they can be understood by every foreman.

(4) Lends safety motion picture films and stereopticon slides for use at workmen's safety meetings and other occasions.

(5) Provides phonographic safety talks, prepared by well known safety men, for use in lunch rooms and at meetings of foremen, safety committees, workmen, and others.

(6) Maintains an employment and registration bureau for safety engineers.

(7) Conducts a speakers' bureau and gives training courses for safety supervisors. Also cooperates with technical colleges and universities in presenting safety as part of a course in engineering.

(8) Aids in the organization of state and local councils in various parts of the country. At the present time there are thirty-five such state or local councils.

(9) Prints a weekly news letter to keep members informed on current events and important matters affecting the safety movement.

(10) Conducts the Annual Safety Congress in some large industrial center where papers and discussions on all branches of accident prevention work are given by experts of national and international reputation and where comprehensive exhibits on safety and other questions relating to industrial relations are shown. The Congress at St. Louis in 1918 was attended by over seventeen hundred persons. The proceedings of the Congress are printed and sent to members. They contain twelve hundred pages of information which is invaluable to the person who wants to study safety.

The Safety Council's Executives

Ralph C. Richards was unanimously elected president of the National Safety Council at the Eighth Annual Safety Congress, Cleveland, O., which was held October 1 to 4. He was one of the organizers of the Council and was a pioneer in the field of railroad safety.

Mr. Richards is chairman of the Central Safety Committee, of the Chicago & Northwestern Railroad, and for more than thirty years has been at the head of its claim department.

During the first five years of the Council's existence, he was a member of the executive committee, vice-president, and, later, an honorary member of that body.

C. W. Price, general manager of the Council, is a man who has had a wide experience in all lines of safety work. In 1911 he was put in charge of the promotion of safety work of the Industrial Commission of Wisconsin, and the

code of safety laws drafted during his tenure has become the standard for many other states.

He helped organize the National Safety Council, and has since been a member of the executive committee, vice-president, and field secretary. In 1917 he was assigned the task of making a survey for the government of all the navy yards and arsenals in the country with a view to placing them on a safe basis.

Sidney J. Williams is secretary and chief engineer of the Safety Council. He is a man with practical engineering experience, a broad knowledge of the mechanical and human problems of industrial relations, and what may be termed a safety soul.

Prior to 1918, when he came to the Safety Council, Mr. Williams, who is a graduate of the University of Wisconsin, was, in turn, superintendent and general engineer of a contracting company, and engineer to the Industrial Commission of Wisconsin. In the latter capacity he was of great assistance to the Government in the development of a plan for the elimination of duplicate inspection in public buildings. He also helped organize and, later, became secretary of the Building Officials' Conference, a national organization. In addition he organized an Industrial Service Conference for Wisconsin employers which still operates under the Wisconsin Commission.

The crotchety surgeon entered the ward at meal time and found only a probationer on duty. In a great hurry to adjust a dressing but unable to find any instruments, he yelled at the only one present that looked like a nurse, "Where's the probe? Fetch me a probe!" The poor little probationer, anxious to please, answered, "Won't I do sir?"

HYDRAULIC PRESSED STEEL COMPANY ORGANIZES BENEFIT ASSOCIATION

The accompanying photograph shows a group of representatives of the four plants of the Hydraulic Pressed Steel Company at Cleveland, who met recently with officers of the company to form a constitution for the new Mutual Benefit Association of the company. Ten representatives came from each plant and, after a day of deliberation, adopted a constitution involving several distinctive features.

While providing liberally for cash awards in case of sickness, the Association is authorized to do many things for the health and well-being of the members. In fact, unlimited scope is given to develop medical and health service cooperative enterprises, such as stores and home building. One of the unique features of the plan is the coordination of four separate plants into one unit—a sort of federal government of four separate units. Each unit looks after its own affairs, but the money is paid into a central fund and is handled by one general secretary. A central re-insurance fund made up of assessments upon the four units forms the protection against abnormal drains upon the funds of any one unit. The central fund is intended to cover epidemics and long-time cases.

The Hydraulic Pressed Steel Company, which has become famous as "more than a place to work," was largely instrumental in initiating the Benefit Association, and contributes one-half the entire cost besides maintaining first aid and nursing service in plant dispensaries. It is the expectation of the company and of the Association that more extensive medical and health service will be immediately developed.

Gathering of delegates from four plants of the Hydraulic Pressed Steel Company at which a new employees' mutual benefit association was formed. The Association expects to develop a thorough and more effective medical service and health program.

MEDICINE AND INDUSTRY

Hygiene, Sanitation, Medical and Hospital Service in Relation to Industry

OTTO P. GEIER, M. D., *Editor*

WHAT THE NATIONAL INDUSTRIAL CONFERENCE OVERLOOKED

No responsible citizen of the republic can escape an interest in the deliberations of the National Industrial Conference, appointed by President Wilson, which began its session on October 6 and expired on Friday, October 24. The Conference refused to take any action toward mediation in the steel strike. The representatives of labor and capital were equally unsuccessful in agreeing upon a platform regarding the application of the principle of collective bargaining. It is unfortunate that the Conference adjourned without having set forward at least some principles which would reduce the destructive warfare that is constantly going on between labor and capital.

In evaluating the results of the Conference, it is interesting to consider the personnel of the Committee. Organized labor was given thirteen representatives, with four additional representatives from the Railroad Brotherhood, making seventeen in all; the United States Chamber of Commerce, and the National Industrial Conference Board were each given five representatives; while the farmers' organization and the bankers' association were allowed three and two members, respectively. One would gather from the above that the organized portions of society had their interests fairly well protected in this Conference. Can we say as much for the interests of the public, which all too frequently finds itself squeezed by the pressure which any two contending forces wish to exert on each other?

It is interesting, therefore, to note who of the fifty-seven varieties of statesmen, appointed to the National Industrial Conference, are represented in the twenty-five individuals chosen to appear in behalf of the public. The official record, "Who's Who in America," reveals the fact that the public was here represented by one broker; two bankers; two socialists, one a writer and the other once an aspirant for public

office in New York; one president of a farm bureau federation; a cotton manufacturer; a clothing manufacturer; three directors of large corporations; one attorney for railroads; one paper bag manufacturer; one wagon manufacturer; one editor of a farm paper; one designated as a lawyer and politician; another known as "potato king"; one Titus, indicated as oil operator and lobbyist; one woman publicist; two women social workers; along with John D. Rockefeller, Elbert H. Gary, of the Steel Corporation, and Dr. Charles W. Eliot, president of Harvard College.

To the readers of MODERN MEDICINE it will probably occur as a bit curious that the one hundred fifty odd thousands of physicians of the country, who have the entire obligation of caring for the health of the people of this nation, should not have been represented in the Conference. Such representation on the Committee, it would appear, might have been of some value, for surely no one knows the intimate living and thinking of the people any more closely than does the physician; strange, therefore, that the physician should not be called into council in the disposition of their individual or group lives.

The one issue that was not controversial in this conference is that of decent living and working conditions. Herein are bound up problems of shop sanitation, the question of working conditions, prevention of occupational disease and accidents, medical supervision with physical examination, to say nothing of the living conditions, housing, and community health programs. These are factors to which the physician of scientific training and social viewpoint might have given invaluable suggestion; and yet his was, of all the professions, distinctly counted out. Who better than he has knowledge of the sanitary standards of plants, the effect of monotony, the subject of fatigue? Who better than he can prescribe adequate ventilation, pure drinking water, adequate toilet and locker facilities? Who should be better informed as to the vitiating effect of dust, fumes, gases, poisons, over-crowding, with

their resultant low output? Who can better diagnose the case of "soreness" on the part of the laborer, whether it is induced by fatigue or whether the "soreness" or dissatisfied state of mind is a forerunner of the fatigue?

These are definite problems which must be weighed in carefully in the final determination by the public as to whether organized industry or organized labor is to have its way in any particular case at issue. Take for example, the coal strike which was precipitated November 1. Here the ultimatum of organized labor is for a six hour day, a five day week, and a 60 per cent increase of pay. They have broken their contract which does not expire until next April. This is but another example of the vicious, ever widening circle of higher costs. The proposed thirty-hour week means a tremendously lowered production, and all this in the face of a shortage of coal even under present working conditions.

It would seem that the public should have something to say as to the cost of coal. It might demand definite information as to whether there is any physical condition surrounding the miner's job which demands only thirty hours of work per week. Here again it is quite possible that the physician, representing the public, might determine what conditions are fair working conditions for the man who is mining our coal.

Similarly the public is concerned and should see to it that the housing, recreational, and educational facilities afforded the miners and their families meet the requirements of modern life and which make for the best type of citizenship.

It is not without reason that the medical profession might properly give testimony as to hours and working conditions in many other labor disputes, where frequently the appeal of the public is entirely based upon bad working conditions, fatigue, and long hours.

EDITOR.

MERCURIAL POISONING

By R. P. ALBAUGH, M.D., CLEVELAND, OHIO, FORMERLY DIRECTOR, DIVISION OF INDUSTRIAL HYGIENE, OHIO STATE DEPARTMENT OF HEALTH

MERCURIAL poisoning occurs frequently in certain trades, particularly in the preparation of mercurial salts and in the felt hat industry. The disease usually assumes a chronic form and is caused by the frequent inhalation of small quantities of vapor. It is said, also, that inhalation of dust containing mercury will produce the disease.

Although mercury boils at 360° C., it volatilizes at room temperature. It is for this reason that it is important as a source of industrial poisoning. Many compounds of mercury, particularly the oxids, are used industrially and cause mercurial poisoning.

Symptoms.—The symptoms of industrial mercurial poisoning are not unlike the symptoms of mercurialism from therapeutically administered mercury. There is usually a marked increase in the flow of saliva, with foul breath and a metallic taste in the mouth. There may be a simple inflammatory condition of the gums, or it may go on to ulceration with loosening of the teeth. The more important symptoms, however, are the psychoses and nervous afflictions, which are usually accompanied by digestive derangements and loss of strength. Patients frequently exhibit a marked tremor before other symptoms manifest themselves. It is not unusual after long continued exposure or repeated attacks of poisoning

for the patient to become emaciated with anemia, loss of strength, muscular atrophy, and disturbed digestion. Such cases may result fatally. Slight cases of mercurialism usually recover, however, if the patient is removed from the influence of the poison.

Prevention and Treatment.—Prevention of mercurial poisoning depends upon the confinement or removal of mercurial vapor and mercury dust as well as strict personal hygiene, particularly proper care of the mouth. In the hatters and furriers trades the danger arises chiefly in cutting, dressing, drying, sorting, and in the subsequent stages of felt hat manufacture. The prohibition of entry into drying rooms while drying is going on, and the removal of vapors and dust at the points of origin are important. The treatment of mercurial poisoning is symptomatic. Patients should be removed from exposure with the first symptoms. Potassium chlorate mouth wash may be used for the inflammatory condition of the mucous membrane. Effort should be made to promote the general condition by strengthening food. Baths and electricity should be resorted to for the nervous symptoms.

"Industry has been in danger of losing sight of the person. Now we get back to people—to men and women whose passions energize the structure of industry."—Ordway Tead in "Instincts in Industry."

WHAT THE WAR HAS TAUGHT US IN SURGERY

BY GEORGE W. CRILE, M.D., CLEVELAND, O.*

THE great contribution of the war to surgery was not the production of hitherto unrecognized methods of treatment, but rather the accumulation of masses of evidence regarding the comparative value of various methods. There is no fundamental distinction between the war patient and the civilian patient. The soldier coming for treatment is in a greater or less degree of exhaustion from the conditions of his environment; the civilian patient is in a greater or less degree of exhaustion from the condition from which he seeks relief. Further exhaustion from the trauma of the operation, hemorrhage, and infection are the prime dangers in each case.

In the army the outstanding requirement is to return every possible man to active service in the shortest possible period of time consistent with a permanent cure. Efficiency in civilian surgery should demand the same. It is to this end that the lessons learned in the field are being studied anew in their relation to the civilian patient.

Immediate Comparison of Data

In the service in the field many lessons were learned. Every theory was tested in the crucible of practical application on a vast scale. We were dealing with hundreds of thousands of patients as we deal with hundreds here. Surgery lived years in days. The combined experience of thousands of surgeons was immediately available for comparison and for study by the individual surgeon; by the surgical staffs of hospitals; by the consultants; by the Red Cross Research Society; by the Interallied Conference; all of whom were seeking to discard the false, to find and to hold fast to the true. All questions pertaining to the care of the sick or wounded soldier were thus studied in detail and in the mass by the nations at war; and, finally, in Paris at a conference of those chosen by their respective governments to make up a consensus of opinion, con-

THE METHOD IS THE MAN

The factors that make for safe surgery are the same in civilian practice as for the man wounded in war.

Theories and counter theories found a practical application on a vast scale during the war. The combined experience of thousands of persons became immediately available for comparison and study, and the results passed upon for standards of practice by those most competent to judge, and the conclusion is:

Good surgery advocates no one method, but depends for its success first, last, and always upon the trained judgment of a competent man.

he will recover if these three menaces can be obviated or successfully treated.

The Menace of Infection

The mere fact that man is surrounded, covered, and penetrated by an infinite number of bacteria, and lives, is a proof that the human body has within itself adequate defense against bacteria. This defense we may be sure has been attained through struggle and survival, that is, through biologic adaptation, and is the bulwark of the treatment of infection. An interesting proof of this biologic adaptation is the fact that the various parts of the body have varying powers of defense against infection, the most efficient defense in general being possessed by those parts most exposed to infection from injury, such as the external soft parts of those which lies in infected areas, such as the intestines.

On the other hand, the inner protected parts, such as bone, especially deeply placed bone, the deep muscles and encased organs and tissues, such as the heart, the brain, the spinal cord, and the retroperitoneal tissue, have had less opportunity to make a selective struggle; hence in these parts weaker defenses against infection have been evolved. What does the tissue of the foot possess that is not possessed by the mediastinum, or by the femur? What does the peritoneum possess that is not possessed by the dura? What endows the skin and the peritoneum with a better de-

clusions from this great mass of evidence were scrupulously drawn.

One fact stands pre-eminent among the many elicited by this vast experience; that is, the prime problems of war surgery as of civilian surgery are shock, anemia resulting from hemorrhage, and infection. Whatever the lesion of the patient, whether it result from war missiles or from disease, provided the lesions are anatomically operable,

fense against infection? The part whose defense is weakest usually possesses a limited blood supply, as compared with parts whose defense is stronger.

The Natural Defenses

There is apparently no other difference as striking, nor as marked as the difference in blood supply. We may then infer that a rich blood supply is the key to the defense against infection. The face and scalp, the external parts of the body, the abdomen, have a rich blood supply as compared with the deep lumbar muscles, the bones, the spinal cord, and the retroperitoneal tissue. Not only is the normal blood supply less in these poorly defended regions, but the local vasomotor mechanism is less developed; hence there is less reaction to the invading bacteria. For the most efficient defense there must be not only abundant blood, but normal blood. As Sir Almroth Wright has shown, the blood must not be acidosed, as when blood pressure is low, for saprophytes flourish in such a medium. The bones, the deep tissue planes, the mediastinum, the spinal cord, the brain, and the retroperitoneal space, are all hazardous regions for infection.

In the mind of the surgeon the body should be charted like the sea, and he should direct his course according to this chart. One region requires one plan of action; another, such as the scalp or the face, no special plan. Face wounds heal almost equally well with good surgery, with poor surgery, or with no surgery. The infected mediastinum heals almost equally badly with no surgery, with poor surgery, or with good surgery. A pulseless patient becomes a universal mediastinum. A limb, anemic, as from a neglected tourniquet or from the severing of the arterial supply, becomes as helpless as the meninges. The war patient in exhaustion from cold and wet and exposure, from loss of sleep and from fighting, and the starved civilian with cancer of the stomach or with perforating ulcers, alike have a universally weak defense. Patients prostrated by shock or by hemorrhage have low resistance. As a rule, defeated, dejected troops have less resistance than victorious troops. The defense, then, in the normal soldier varies with the several parts of the body, the frontiers of the organism being best defended. The defense, even at the frontiers of the organism, is lowered by interference with the local blood supply, whether of an entire limb, or of the devitalized bloodless tissue along the injured track of the missile; it is weakened by low blood pressure from shock, with its secondary anidrosis; or by hemorrhage. It is weakened when the entire individual is in exhaustion. The de-

fense, in turn, is augmented by rest, by sleep, by fluids, by the revision of wounds, by restoration of the local and general blood supply.

Aids to Local Resistance

In addition to these measures which augment the resistance of the organism as a whole, it is essential to increase the local resistance as well. Whether we are dealing with a war or a surgical wound, this may be secured by vitalization of the part attacked; by physiologic rest; by destruction of contaminating bacteria; by the application of heat.

The vitalization of war wounds is accomplished by the excision of every particle of devitalized soft tissue and bone; by removing every particle of foreign material,—clothing, mud, missiles,—in such a manner that there is no added *surgical* devitalization from goading retractors or rough handling of fractures. Vitalization is promoted also by making sure there is no interference with the blood supply and by employing a minimum of foreign material for treatment, such as tubes, etc.

The wound may be further vitalized by moist or by radiant heat. The vitality may be maintained by overcoming infection; by preventing pooling of wound secretions. Therefore, in recessed wounds the Carrel-Dakin treatment does best. The deeper and the more recessed the wound, the greater the indication for Carrel-Dakin. It is always to be borne in mind that the operation must be done lightly and sharply; for if there be rough handling, needless moving of compound fractures; if piercing hooked retractors tear the flesh; and if intermittent muscular contractions grind tissues between the ends of ragged bone fragments, then the net result of the operation is the substitution of surgically devitalized tissue for the devitalized tissues of battle casualty.

Essentials of Physiologic Rest

Physiologic rest includes more than mere muscular and psychic rest; it implies equally *cellular rest*. Living cells are disturbed by air, by desiccation, by physical contact of dressings, by many chemical antiseptics, and by bacterial toxins. These points have been strongly emphasized by Sir Almroth Wright whose teaching has placed a renewed emphasis on the importance of the *cellular* protection of wounds to ensure cellular physiologic rest.

To secure physiologic rest in the case of a fracture an even, adequate, continuous extension must be made, an extension sufficient to prevent the goading of soft tissues by sharp bones and to prevent body fragments from grinding one another. Physiologic rest of the soft parts indicates

mass quiet by means of supports, such as splints, slings, swings, and extension suspension. It means for compound fractures and for injuries of the soft parts no tight bandages, no tight stitches, no accumulation of wound secretions,—blood, serum, etc. For open wounds it means that antiseptics must not be damaging; that dressings must be painless; it means elevation of extremities for comfort, and the prevention of swelling. For visceral injuries it means absolute rest, low diet, freedom from excitation, associated environment.

Destruction of Contaminating Bacteria

The first and most dependable agency for the destruction of contaminating bacteria is the bactericidal power of tissues. This normal defense of tissue against bacteria is present only in living tissues, and the ability of living tissue to overcome infection depends on its vitality. Normal living tissue has strong bactericidal power. As vitality is impaired down to the death point, so is the bactericidal power impaired to the zero point. Moreover, when infection begins, the infecting agent itself has the power of diminishing the vitality in advance of the infection through chemical injury, tension, and swelling.

Thus, as Kenneth Taylor, Cuthbert Wallace, Bashford, and others have shown, many anaerobes cannot live at all in normal tissue, but only in damaged tissue. The anaerobic invasion is made possible only by injury through chemical action, through shell injury, through swelling or anemia, or shock and exhaustion, whereby the resistance of the tissue is lowered. Therefore in a compound fracture that is settling down, one goading by a sharp fragment of bone will devitalize a small area and, in consequence, an area of infection with the advancing tissue damage will be established. Therefore, we may say that the whole wound is defensively only as strong as its weakest point; if the defense line is broken at one point, the entire line of defense may give way.

Methods of Antisepsis

As for the relative value of the various methods of antisepsis it is difficult to choose among them. Perhaps the method which has proved most universally useful, excepting under battle conditions, is the Carrel-Dakin. This is of value in wounds with necrotic tissue, in empyema, in recessed wounds with a tendency to pooling of the wound discharge, and as a general method. Carrel and Dakin have made an outstanding contribution to surgery. Dichloramin-T, flavine, bip, or Wright's hypertonic solution, each has its

value under certain conditions. Perhaps most useful of all in civilian surgery after Carrel-Dakin is flavine, which is non-toxic and can be used for days without ill effect. It is of special value in multiple stage operations in which it is necessary to keep the wound *in statu quo* for a limited period, as in certain cases of exophthalmic goiter. It should be noted that it is not used in contact with silk sutures as it dissolves them.

The therapeutic value of heat has been sanctioned by the experience of physicians and of the laity since the dawn of medical history. The therapeutic place of no other agency is as secure. Moist heat, dry heat, radiant heat, electric light, sunlight—all favorably influence the infections.

In what way may heat exert its beneficent influence? Granting the premise that the natural defense of the organism against infection is made through the agency of phagocytosis and the chemical antagonism of the blood plasma, it becomes evident that in either case the defense is chemical. The fact that the defense is chemical gives at once a clue to the mechanism by which heat assists the defense against bacteria. It is probably because with the rise of each degree in temperature in any system, inorganic or biologic, the chemical activity is increased 10 per cent and the electric conductance 21 $\frac{1}{2}$ per cent. The increased chemical activity increases the chemical defense; the increased electric conductance increases the metabolism. Therefore, we may suppose that heat accelerates the chemical defense as far as it involves the metabolism of the phagocyte, and as far as it involves chemical defense of the blood plasma, and that heat aids also by increasing the total amount of blood in the inflamed part, thereby increasing the number of phagocytes. Moreover heat assuages pain.

An Interesting Analogy

In this discussion of infection an interesting analogy between appendicitis and the war wound suggests itself. In a case of acute appendicitis, if the dead appendix is removed before the infection has invaded normal tissue, then the wound is closed immediately, primary union follows and the vast possibilities of the inflammation of the great abdominal cavity will be averted. Likewise, if the dead tissue in the track of a war wound is excised, before living tissues are invaded, the inflammation of a great mass of soft tissue will be averted. In appendicitis, even after the infection has penetrated the wall of the appendix and invaded the peritoneum, excision of the dead appendix will facilitate recovery. In war wounds, even after the infection has passed

beyond the devitalized tissue, excision of the devitalized tissue will facilitate recovery.

When an appendicitis has developed into a localized abscess with an organized wall of granulations, the surgeon deals with the abscess as such. When the infection in a war wound has developed into an abscess with new tissue organization, no débridement is done, but the abscess is treated as such.

In the war wound the stage of contamination of dead tissue, the period before infection develops, corresponds to the period before infection from a dead appendix penetrates the wall. In this period if the dead appendix is excised cleanly, the patient recovers; if the dead tissue of the war wound is excised cleanly the patient recovers. Appendicitis and war wound infection develop through identical phases: localized infection, spreading infection, abscess. If an appendix abscess is roughly handled, spreading peritonitis, pyelephlebitis, bacteremia, etc., may result. Comparable results follow when an infected war wound is roughly handled.

Appendicitis was not mastered until the surgeon had learned accurately to forecast its future, in other words, until he took the initiative away from the disease and attacked instead of defended. In like manner in the case of the war wound the military surgeon discovered that as long as he left the initiative to the infection, he could not achieve mastery. To wait in the case of a devitalized war wound until the infection had spread widely until there were pain, swelling, redness, and tenderness, was to court defeat. Like the to-morrow of the appendix, the to-morrow of the war wound must be read today, and action taken today.

An antiseptic does not cure appendicitis—it does not cure the war wound. There is no difference in principle or in practice between the treatment of appendicitis and the treatment of war wounds. The time factor is equally vital; the treatment is comparable; the natural defense is identical.

Shock and Hemorrhage

The consensus of opinion of the Interallied Surgical Congress and the British and American surgeons in military service generally may be summed up in the following brief dictum: *The best treatment of hemorrhage and shock is rest, warmth, morphin for pain, fluids, and blood transfusion.* Civilian surgery and war surgery in their relation to shock present one important difference. The depleted civilian patient may be in a "pure-shock" state when he comes under the surgeon's care; the wounded soldier is often in

shock. Nevertheless, identical methods will prevent the development of shock in the first case and will successfully combat the present shock in the latter.

Physiologic Rest.—Physiologic rest includes psychic, as well as physical rest. It means reassurance; it presupposes an atmosphere of quiet and confidence; it requires optimism as well as skill. Physiologic rest can be achieved only by the cooperation of surgeon and intern, nurse and orderly.

Warmth.—The loss of power to create body heat is one of the damaging effects of shock, for the organism is much injured by a subnormal temperature. The application of heat, therefore, is one of the essentials of the treatment and of the prevention of shock. The most readily applied form of heat is hot air under blankets. Under war conditions hot water bottles and other forms of direct heat are not useful because of the time required for application and because of the danger of producing burns.

Morphin.—If the patient has pain, if he is restless and, if the pain and restlessness cannot be otherwise relieved, morphin in one-sixth grain doses may be given until the pain and restlessness is overcome. There is evidence that morphin in still larger doses is specifically useful.

Oxygen.—If there is a wound of the chest which interferes with the supply of oxygen, oxygen is to be given. If available, all cyanosed, all gray-blue patients, all shallow breathing patients should have oxygen. A nitrous oxid machine for giving anesthetics is an excellent means of administering oxygen under pressure.

Administration of Fluids.—Water in some form should be given, preferably by the mucous membranes. Sodium bicarbonate in a 5 per cent solution and combined with 5 per cent glucose is most effective; but in acute, grave cases from 2,000 to 4,000 cc. of fluid should be given each twenty-four hours. Water intravenously is rapidly eliminated from the body. Water absorbed through membranes or tissues is retained in much larger amounts. Water, to be most useful, should have a biologic pass.

The Dangers of Low Blood Pressure

The damaging effect of low blood pressure is prevented or overcome (1) by elevating the foot of the bed; and (2) by early transfusion. The Bayliss solution of gum acacia may be used. It has the advantage of being more readily available than blood. Under war conditions donors for blood transfusion are usually numerous among the lightly wounded patients.

One of the greatest errors is to allow a patient

to remain in a state of low blood pressure in the hope that he will improve through his own resources, reserving a blood transfusion to be used as a last resort after it has become obvious that the patient is going to die. This is the same faulty logic that was once used in dealing with appendicitis. When the indication for operation in appendicitis was supposed to be a clammy, pulseless state, when the patient was dying, surgical treatment became almost discredited. It is equally illogical to wait for impending dissolution in shock before improving the circulation. Treatment should not be deferred until the inaugural state of death is established.

There is another method of treating shock which is not generally applicable to war conditions, that is narcotization with morphin, giving morphin on the same scale as in the Alonzo Clark treatment of peritonitis, *i. e.*, keeping the patient under morphin so completely that the respirations are cut down to about twelve to fifteen per minute and the patient is deeply asleep. During this time between 2,000 to 3,000 cc. of normal saline infusion should be given subcutaneously. When properly carried out, excellent results may be obtained by this method; however, it should never be employed if there is cyanosis, and never routinely, and never except under expert supervision.

Modus Operandi

The interallied Surgical Conference adopted as one of its conclusions that in the treatment of wounded soldiers *the anesthetic of choice is nitrous oxid-oxygen combined with local anesthesia*. Among the evidence offered in support of this tenet Surgeon General Sir Anthony Bowby presented the work of one of the most brilliant British military surgeons, Capt. Douglas C. Taylor, and the work of the Chief of the Anesthetic Service of the British Army, Capt. Gregory Marshall. The experience of Capt. Taylor I am privileged to quote as follows:

Until the summer of 1917 my colleague, Capt. G. Marshall, invariably gave ether for my laparotomies for gunshot wounds of the abdomen. No series of 100 consecutive cases showed a recovery rate of much over 50 per cent.

During the summer and autumn of 1917 I did 101 laparotomies for abdominal wounds, and nearly half of them were given nitrous oxid and oxygen, combined with infiltration of the abdominal wall with eucain and novocain. The more serious cases, *i. e.*, those with rapid pulse and low blood pressure, were nearly all done by this method.

Of this series, 27 died at the Casualty Clearing Station, and 74 were evacuated to the Base; of the latter there have been only two deaths, both from secondary hemorrhage, one from the kidney and the other from the rectum and buttock.

By the employment of anociation, the mortality rate in Captain Taylor's series was reduced from approximately 50 per cent to 29 per cent.

Captain Marshall has demonstrated that patients may apparently do well during ether anesthesia but do badly afterward, while they do well both during and after nitrous oxid-oxygen anesthesia.

The experience on a large scale of the resuscitation teams from the Lakeside Unit which served continuously throughout Field Marshall Haig's great offensive in Flanders in 1917, during which there were over 800,000 casualties, showed that in abdominal operations somewhat better results were obtained if before the beginning of the operation sufficient blood were transfused to permit a safe performance of the operation; and again at the completion of the operation an ample amount of blood up to 750 cc. were given. Furthermore, if a let-down appeared later, the transfusion might be repeated. Meanwhile, the advantages of comfort, rest, warmth, morphin, and fluids were added.

The advantages of nerve-blocking are further emphasized by Colonel Cabot's series of 180 amputations of the thigh, one-half under ether, one-half under spinal anesthesia with a reduction of mortality by the use of spinal anesthesia of 50 per cent; while Captain Taylor by the use of nitrous oxid-oxygen and local anesthesia reduced his mortality rate from thigh amputations more than 200 per cent.

It would seem from these conclusions of the Interallied Surgical Conference regarding that the technic which would deal most successfully with infection, shock, and hemorrhage in exhausted soldiers in whom bullets or shell fragments had ploughed their way through septic material into the hollow viscera should provide even greater protection to the civilian patient in whom avenues into the viscera are opened under the utmost aseptic precautions. It is for this reason that perhaps among the most vital lessons brought back to civilian practice have been those learned from the treatment of abdominal wounds.

Treatment of Abdominal Lesions

In civilian surgery the principal sources of infection are the appendix, the gall-bladder, the tubes, perforating ulcers, or an infection incident to the operation itself. In military surgery the source of infection may be clothing, missiles, or the contents of the hollow viscera, especially the last.

In our military experience near the front line and at a base hospital we found that the defense against infection in the soldier in many instances

was greater than that in the average patient. The general resistance, the vitality of the soldier had been increased by his training, the open air life, wholesome diet, regular hours, and physical exercise; and the muscles of the intestinal walls, like the muscles of the legs, had become larger and stronger. If the perforated hollow viscera had been closed, fresh soldiers, whose splendid general condition had not been greatly impaired at the time they were injured, rarely died of peritonitis. In the heavy winter campaigns death was due to bronchopneumonia, shock, exhaustion, etc., rather more commonly than to peritonitis. On the other hand, soldiers wounded after a protracted and exhausting season at the front, especially if cold and wet as was almost universally the case during the winter months, with their general resistance lowered by bodily fatigue and mental stress, such cases bore operations for penetrating abdominal wounds badly. The acute reduction of vitality in these fatigued soldiers is comparable to the lowered vitality of civilian patients reduced by chronic disease such, for example, as cancer of the stomach.

The prime problem of abdominal surgery, then, is the problem of the patient with lowered vitality, reduced resistance, be that patient a wounded soldier or a diseased civilian. It follows logically that the first measure is to increase the general resistance. If immediate operation is not imperative, the vitality of the patient may be increased by the obvious measures of diet, fresh air, and, above all, rest and sleep, until a favorable condition for operation is attained.

In the soldier with perforated intestines, however, and in the starved civilian patient with partial obstruction, or with acute infection, operative measures cannot be postponed. In these cases the administration *per rectum* of a 5 per cent solution of soda bicarbonate with 5 per cent glucose and an immediate transfusion of blood may effect a sufficient restoration for the operation or at least for the first séance of a two-stage operation under strict asepsis, nitrous oxid-oxygen analgesia, local anesthesia, and the minimum amount of manipulation required to complete the operation; or, in grave situations, to make a sufficient anatomic adjustment to save the patient until an interim of rest and restoration has sufficiently increased his vitality to permit the performance of the second and major stage of the operation.

Points in Operative Technic

As for the technic of the operation, whether it be performed in one or two stages, whether it be the removal of an appendix or gall-bladder, re-

section of the stomach or colon, removal or tumors of the ovaries or uterus, or—in the wounded soldier—the repair of intestinal rents or perforations, every step should be under complete asepsis with nitrous oxid-oxygen anesthesia or analgesia, supplemented by ether only when it is necessary to secure increased relaxation during the exploration, novocain infiltration, gentle manipulations, and sharp dissection.

The essential points in the associated treatment of abdominal infection, therefore, are the following: (1) nitrous oxid-oxygen; (2) anesthetized incision; (3) accurate, clean cut operation to diminish both infection and shock; (4) adequate drainage; (5) Fowler's position; (6) vast hot packs over the entire abdomen, spreading well down over the sides; (7) 5 per cent sodium bicarbonate with 5 per cent glucose by rectal tap, continued as long as it is tolerated; (8) primary lavage of the stomach, repeated only if indicated; (it will rarely be indicated if asepsis is complete); (9) from 2,500 to 3,000 cc. of normal saline subcutaneously every twenty-four hours until the period of danger is past; (10) morphine hypodermically until the respiratory rate is reduced to from 10 to 14 per minute and held to this rate until danger is past.

Under this combination of the asepsis of peritonitis with the associated operation my associate, Dr. W. E. Lower, and I have performed 409 consecutive operations for acute appendicitis, with or without generalized peritonitis, without a death.

The Good Surgeon

The surgeons and the pathologists who for four years have intensively studied war wounds, have formulated many theories of treatment, many apparently contradictory theories. Thus there have been presented the claims of the value of various chemical agents against those of no chemical agent; of moist dressings against dry; of heat against cold; of frequent dressings against infrequent, and of no dressings against both; of sunlight and of electric light against occlusion; of immersion against hot air; of bacteriological control against clinical judgment; of vaccines, toxins, and foreign proteins against normal reaction; of wound inoculation with harmless organisms against wound sterilization; of isotonic against hypertonic solutions; paste has competed with paste; bip with bip; sap with both; and chronic pastes with all.

Does not this intensive study of infection in war wounds for this comparatively short period equal and recapitulate the more leisurely study of infection during the thirty years since Lister

first proposed the carbolic spray? And is there not slowly emerging from the present conflict of opinions the same fact as that which emerged from the post-Listerian period—that the one agent of successful surgery, whether war surgery or civil surgery, is *the good surgeon?*

In civil surgery here in America, by what agency was mastery achieved over appendicitis, over cholecystitis, over tubal infection, over adenitis? What agent has contributed the most to the success of resection of the intestines and of the stomach; of gastroenterostomy; of treatment of suppurating stone in the kidney; of the treatment of infection of subcutaneous tissue? What agencies have achieved survival? One and but one—*the sound surgeon*, who always creates opportunity. Is it possible that in these four intense years of war surgery in which more experience in traumatic surgery has been accumulated than during the past thirty years we have traveled around the same circle as in civil surgery and have again found *the same surgeon?*

Exponent of No Single Method

By sound surgery we mean the assumption of complete inclusive responsibility for every item that enters into the result; the consideration of the wound as well as the patient; the development of an ability to read the wound as well as the man, aright. Sound surgery means quick, innocuous, timely intervention; it means seeing clearly the to-morrow of the wound; it means no intervention unless there is to be a net gain; it means a sharp knife, a good anesthetic, a painless innocuous dressing; it means as much respect for the tissues of the anesthetized man as those of the unanesthetized man; it means a training in judgment that unerringly tells when to cut, how far to cut, when to quit cutting; it plays all the defenses and reparative forces of the patient.

Good surgery is the exponent of no single method. It recognizes the anatomical and environmental situations in which chemical and physical agencies are useful. Good surgery exploits physiologic rest, and fluids, and sleep; it gives little pain. Good surgery evokes confidence, and confidence begets restoration. Good surgery, then, makes use of antiseptics and physical forces, just as it uses incisions, counter-drainage, revisions, skin grafting, blood transfusion. Good surgery does not substitute an easy formula for its principles; above all, it always is dissatisfied with its work and always is open to suggestion.

What could the good surgeon accomplish with the wounds of war with good opportunity but no antiseptics? Without antiseptics he could close by primary union a higher percentage of con-

taminated wounds than with antiseptics; he was able to remove damaged tissue with such accuracy that the natural defenses of the revised wound became its best antiseptic; he closed penetrated knee joints more securely without than with antiseptics; he closed penetrated skulls without, better than with, antiseptics; he cleared up foul and infected superficial wounds as well without as with antiseptics; he met gas gangrene with the timely use of the knife as well without as with chemical agents. He closed healthy superficial wounds with early suture tied lightly; healthy wounds that could not be closed by suture he closed by skin-grafting, both as a healing and as a bacteriocidal policy; he closed fecal and urinary fistulae without antiseptics.

On the other hand, he realized equally that in compound fractures with or without bone infection, in deep, recessed wounds in pyogenic infection in many other types of wound that antiseptics might have great advantages, and he used them and used them well. In certain phases of a wound he would use Carrel-Dakin; in another, acetic acid; in another, hot pack; in another, incision—a physiologic incision today to avoid the tissue-tension of tomorrow; in another transfusion; in another, sunlight or electric light; in another, continuous alcohol to make a scar covering. In the rush of a great battle, he incised for drainage and, in addition, he made physiologic incisions to avoid the tension that is sure to follow the next day from the inevitable infection.

But in quiet times, he dissected out every atom of devitalized tissue. He read accurately not only the wound, but the patient; not only the patient, but the military situation; not only the military situation, but the condition of the infecting soil, the state of transport, his surgical assistance, and the type of nursing care; that is, he weighed accurately his chances for success. Therefore, the army medical service and the wounded man pinned their hope and their faith first, last, and always to the one agency of wound treatment that in civilian surgery emerged clearly from the confusion of the Listerian period, emerged clearly from the confusion of the four years of military surgery—*the sane, sound surgeon.*

Asks Military Rank for Nurses

Among resolutions adopted at the meeting of the American Hospital Association was one which called upon Congress to bestow military rank upon nurses of the military and naval forces. The resolution urges that military rank be given nurses relative to the rank of officers having corresponding responsibilities and authority in order that they may properly and efficiently discharge their duties and, also, in order that hospitals and training institutions may be able to induce capable women to enter the service and to undergo training.

HEALTH EDUCATION IN INDUSTRY

BY W. A. EVANS, M.D., CHICAGO*

IN THE fight against premature death and disablement due to accident, injury, and illness progress is being made in certain directions but not in others. The bacterial diseases, with the exception of pneumonia, bronchitis, and influenza, have been very greatly decreased. The death rate of infants and older children from all causes has been greatly decreased. These two decreases have been considerable enough to lower greatly the death rate. Heart disease, Bright's disease, apoplexy, and diabetes have very materially increased.

Individual Habit and Community Custom

We attempt to make a distinction between diseases due to habits and those due to customs. For instance, the bacterial diseases in the main are spread by community customs. The habits of the individual are of lesser importance than the mass habits called customs. On the other hand, in the case of diabetes the larger factor is the habit of the individual. While many flaws can be picked with this classification, in the main it serves to make a useful distinction with a reasonable degree of accuracy.

Applying the rule, we find that in the main the diseases which are on the increase are those due to faulty habit. Another line of division would be on the basis of organized effort at prevention. Applying this rule broadly, we find that the improvements have been in that group where preventive effort has been made and the lack of improvement has been in those where there has been neglect.

When we come to study accident rates we find that there has been a tendency upward for fifty years. The fatal death rates from all external causes by decades in Chicago since 1867 have been:

1867-76	93.2
1877-86	90.6
1887-96	122.6
1897-1906	106.3
1907-16	120.8

The most effective method of health education is by personal, individual work.

Personal hygiene and safety work when viewed from the standpoint of the general pronouncements on public health are cut from the same cloth. So also is accident prevention.

In the main, diseases which are on the increase are those due to faulty habits. To bring about the desired end, the habits of the people must be changed. Each person, while his muscles are doing their customary work, must be taught to carry in the back of his head a subconscious realization of hazards and an instantaneous response to stimuli of danger.

The rates for 1917 and 1918 were 118.1 and 99.8 respectively.

In an effort to analyze these figures I have come to this conclusion: in the rearrangement of the classification of the causes of death it would be wise to divide external causes into those where there is intent to injure and those without intent. The former are not related to carelessness. In this group there should go suicides, homicides, and legal

executions—numbers 155, 155a, 155b, 155c, 155d, 156, 157, 158, 159, 160, 161, 162, 163, 177, 182, 183, 184, and 186a—eighteen causes in the Bertillon classification responsible for more than one-fourth of the deaths due to external causes.

I suggest that when the next revision of the Bertillon classification is being considered you be represented and that you endeavor to bring about such revisions in the nomenclature and classifications as will make it easier to marshall the facts relative to accidents. Also that you have proper governmental agencies collect and tabulate non-fatal accidents.

Rising Death Rate in Some Groups

Returning after the digression, we find that the tendency of rates for deaths from all causes to rise is due to a rise in the rates for homicides, suicides, and what have been termed public accidents, and that this rise has been enough or more than enough to compensate for the decrease in industrial accidents.

Between 1913 and 1917 the number of fatal accidents in industry fell from 25,000 to 22,000, an improvement of 12 per cent; the number of serious accidents from 700,000 to 500,000; and the number of accidents serious enough to keep a man from work six weeks or more from 300,000 to 26,000, a fall of 26 per cent. This improvement was due to education of both employer and employee, and the use of safer types of machinery.

*Read before the Eighth Annual Safety Congress of the National Safety Council, Cleveland, Ohio, October 1-4, 1919.

During the last seven years the employer class has become greatly interested in accident prevention, the employee class moderately so, but the interest of the general public has lagged far behind. In 1917, of the 77,000 fatal accidents in the United States registration area 55,000 were outside of industrial plants. Of the 510 fatal accidents in St. Louis in 1917, 400 were outside of industry. Of the total death rate from all causes in the registration area of about 14 a little more than 1, or one-fourteenth of the whole, is due to violence. In 1901-5 the violence rate was 101.7; in 1906-10 it was 1.07. Since 1910 it has been: 1911, 1.04; 1912, 1.04; 1913, 1.08; 1914, 1.02; 1915, 0.99; 1916, 1.05.

Accident Prevention Policy Needed

As a side light showing the importance of fatal accidents in determining the total death rate, I call your attention to the appended table.

This table shows the death rates per 1,000 from disease and from accidents in the Canal Zone among employees between 1906 and 1907 and compares them with the fatal accident rate in the registration area in the United States. At one time the fatal accident rate in Panama was four and one-half times that in the United States. It is even yet one-third higher. The death rate from disease fell from a maximum of 40.5, thanks to intelligent, well supported effort. The very high fatal accident rate fell only from 4.52 to 1.35 minimum. I hope when we come to build another canal we will have an accident prevention policy

TABLE SHOWING NUMBER OF EMPLOYEES' DEATH RATES FROM ALL CAUSES, DEATH RATES FROM DISEASE AND DEATH RATES FROM EXTERNAL CAUSES AMONG THE EMPLOYEES OF THE PANAMA CANAL ZONE, 1916-1917, INCLUSIVE

Year	No. employees	Death rate	Disease death rate	External causes rate
1906	26,547	41.73	39.66	2.07
1907	39,238	28.74	25.44	4.30
1908	43,891	13.01	8.65	4.33
1909	47,167	10.64	7.55	3.09
1910	50,892	10.98	7.5	3.48
1911	48,876	11.02	7.65	3.38
1912	51,852	9.26	6.36	2.81
1913	56,654	8.35	5.24	3.11
1914	44,329	7.04	4.40	2.64
1915	34,755	5.77	4.05	1.72
1916	33,176	6.03	4.58	1.45
1917	32,589	7.09	5.74	1.35

NOTE THE FOLLOWING POINTS:

- (1) The personnel referred to were almost all adult males.
- (2) Negroes predominated.
- (3) The work was done largely out of doors with heavy machinery. The climate was unhealthy but the efforts to control disease were exceptional. In none of the reports is there any stress put on accident prevention.
- (4) The fatal accident rates of 1908 (4.33) and 1907 (4.30) were higher than the disease death rate of 1915 (4.05) and only 1.44 per 1,000 less than the death rate from all causes in 1916.
- (5) The death rate from disease after 1911 was exceedingly low.
- (6) The death rate from accidents was very high every year.
- (7) The improvement in the death rate from disease is far greater than the improvement in the fatal accident rate.
- (8) Doctor Gorgas explains that the very high death rate from disease in 1906 was due in greater part to an epidemic of pneumonia.
- (9) The rapid rise in the death rate due to external causes in 1907 he explains is due to more blasting and railroad work.
- (10) In 1906 he says there were 35 deaths among the white employees of which 19 were from disease and 16 from violence.

comparable to the disease prevention policy employed when the Panama Canal was being dug.

After showing the steady decline of accidents in industry between 1913 and 1919 Payne says: "There is another story for public accidents or accidents occurring in the home, on the street, and generally outside of industrial establishments. There has been a marked growth in the number of this type of accidents in the past few years. The reason for this rapid increase in the number of public accidents while the industrial accidents have as rapidly declined, is that industrial managers are thoroughly aroused to the necessity of accident prevention in their plants, but the public in general is still unconscious of the significance of safety."

A Change of Habits Involved

To bring about the desired ends it is not enough to inform and instruct. That does not go far enough. The habits of the people must be changed. Each person must not only know what practices are safe and what hazardous, but he must apply it to himself. In the back of his head he must carry the thought constantly. While his mind runs in its proper grooves and his muscles are doing their customary work, there must be a subconscious realization of hazards and an instantaneous response to stimuli of danger. It may be that a tendency to go about in an absent-minded trance must be corrected or that a natural incoordination and clumsiness must be overcome.

This is the problem. How can it be solved? The solution, when found, is to be applied to the employer group including general managers, superintendents, and all bosses, the employee group including all who feel no responsibility for others, and the general public. The employer group are very well informed, but for one reason or another many are indifferent; at least, many do not act at all and others act somewhat thoughtlessly. The employee group are less well informed and less interested. The general public are most in need of information and of interest.

Mass Habits by Decree

Recently a great professor in a great university wrote as follows of personal hygiene: "Personal hygiene is not a subject that can be advanced by public meetings. It has to be worked out by, or with, each person individually." A good answer to this opinion appeared in the headlines of a daily paper issued about the time this letter was received. It read: "Dress designers call for larger hips this season. Checks and stripes and lots of yellows appear to be favorites."

When fashion decrees that hips are to be

larger, hips will be larger; or that checks, stripes, and lots of yellow are to be worn, you can bet they will be worn. It will scarcely be denied that fashion determines wearing apparel, clothes, shoes, the shape of the feet, in great measure the food and the methods of its preparation, and in some measure hours of sleep. Now no one will contend that fashion is worked out by or with each person individually. An impulse, or not infrequently a convention of the interested, issues a decree and forthwith the civilized world obeys it. There is no other field where there is so little individuality, so little work by or with the individual.

All of the items specified in the above paragraph—clothes, shoes, food, sleeping hours—are matters of personal hygiene. Now, personal hygiene is a matter of good habits on the one hand or bad ones on the other; and so is safety work; when viewed from the standpoint of the general public work pronouncements, feats, discussions, are cut from the same cloth. What I have said about personal hygiene applies to accident prevention; if there is no field for any but individual effort in personal hygiene, the same holds true of accident prevention. On the other hand, if public work pronouncements, feats, discussions, newspaper articles, publicity, can affect changes in matters of personal hygiene they can be effective in accident prevention.

Limitations of Individual Effort

I agree that the most effective method of education is by personal individual work. I am for it as strong as any one; but it has limitations which make it impossible as a solution of our difficulties. It is tedious, expensive, and requires too much machinery to be practicable as a means of meeting the whole situation. There are great possibilities for the group method even in educating adults. I propose to discuss some phases of some of the group methods.

Education by means of moving pictures is so well understood that I need not say much about it, but let me offer you this suggestion. Try one short run of lessons in a program of lighter stuff. When health commissioner of Chicago twelve years ago, I found that evenings devoted to health talks and health pictures lost their pulling power; whereupon I sent around to the moving picture places single reel health films to be run unannounced between two numbers of the regular program, the audience being assembled with no thought of a health reel and in the main indifferent to such a subject.

Cards, bulletins, and booklets are always useful. I recently read a criticism of the propaganda

cards of the Chicago health department; for example, such a card as this: *Swat the Fly*, or this: *Dirty Air Means Death*. The particular card objected to was one saying that any sore throat was liable to be due to diphtheria bacilli and calling for throat culture in every such case. The card was one displayed in street cars. The criticism was that the statements should have been qualified; that more information should have been conveyed; that brief, dogmatic, pragmatic statements are always inaccurate. Of course the criticism was justified. The Chicago Health Department recognizes this. They would not offer this card as a treatise on diphtheria; on the other hand, a treatise on diphtheria has no place in the advertising space of a street car.

Putting Over the Message

Once a pedagogue criticised a statement of mine to the effect that I was educating people stating that I was instructing them. As I understand it the word *sharks* say that a man instructs when he imparts information but that he does not become an educator unless the instruction imparted "changes the ways of those who receive it." Now an essay on diphtheria is instructive, but the chance that a street-car card will cause somebody to change his ways is much greater if it uses a few words and perhaps a picture to put over a message.

There is a place for the longer treatise, the essay. The whole question is one of salesmanship. Here are some men with information—the goods. Here are a lot of men in need of the goods, but not especially anxious to buy. How can the goods be sold? That is the question. As I see it the place of the complete treatise is for distribution among the leaders. The others will not read it nor understand it. The purpose is to instruct the leaders with a view to having them translate the information, precept, or point of view into the psychology of the followers. The purpose of the short statement is to arrest the attention and secure the adoption of the man who is not greatly interested, who will not give attention for long, who will not make fine distinctions and who will not try to remember.

Psychology of Selling

The men who advertise goods know the selling power of a slogan. Slogans to be effective must be short, catchy, and easily remembered. They must be positive. Negative slogans are not so effective. They must imply action. "*Swat the Fly*," fills all the indications well, "*Do Not Spit*," does not. In making cartoons, size of type, color

schemes, pictures, are matters to be carefully thought out. The use of slogans comes under a well recognized principle of advertising. In the words of Lord Fisher, "Reiteration is the secret of conviction." It is well to change cards, frequently as to location, type, color schemes. We become inattentive—blind, to anything that is steadily before us. So much for the cards.

In between the cards and the booklets there comes a place for the leaflet. As to leaflets I have certain suggestions to make. The fundamental suggestion is that you bear in mind the psychology of the men to be approached, giving it preference over the subject matter to be presented. Based upon this are the following suggestions:

Use should be made of the universal love of gossip.

Wherever it is good judgment, bulletins should say something about individuals, using names, addresses, and incidents, news of the plant.

Incidents and occurrences should be made the basis of stories.

Records of accidents should be published making use of the spirit of competition.

Advantage should be taken of symptoms, disorders, diseases, and accidents to distribute leaflets.

There should be a series, with one for each group of subjects.

I get between fifty and one hundred letters a day. An analysis of these letters shows that for every one interested in prevention, there are ten interested in the cure of a developed disorder, the actual figures being 66 and 660. This shows that the overwhelming interest is in developed conditions. "The devil was sick—the devil a monk would be." Although I write most about hay-fever in the spring, nine-tenths of the people who write me about hay-fever write well after the onset of the hay-fever season.

Habits and Degenerative Diseases

Most diseases of the degenerative group are the result of bad habits. The most effective way to write about a given bad habit is to tie it up with some disease which grows out of it. For one illustration—tell the news about some person with diabetes, then touch on diabetes in general and, finally, expiate on the habits of excessive sugar and bread eating; or give the news of some accident, tell of accidents of this type, and then dilate upon carelessness. These make ideal presentations. In these longer presentations I can see no objection at all to exciting controversy.

Recently, on successive nights I went to a forum where the room was crowded, as it always

is, and to a meeting of the board of directors of another forum called to discuss the advisability of discontinuing because of lack of interest and non-attendance. The reason for the success of the first was knowledge of salesmanship, and of the failure of the latter lack of such knowledge. I inquired of the platform manager as to the reason of his success. Among other things he told me was this: Always start a row. Always make somebody mad. Meetings thrive on controversy. Occasional bulletins containing controversial matter is in line with good salesmanship.

A Special Angle for Foreigners

The approach to foreign-language-speaking people is at once easy and difficult. They do not read English and most of them read very little in any language; but this very fact means that their minds are not dulled by a multitude of impressions. Anything that you can get across goes big. Slogans are usually slangy. Slang does not translate well. Prizes for slogans in tongues other than English will bring forth some that are catchy for foreigners.

I suggest that concerns employing foreign-speaking people use the newspapers of those people for accident-prevention education. They read their newspapers through, even to the advertisements. I suggest that in matter written for these newspapers there be some stories written with the thought of the harmfulness of carelessness, the inferred benefit of caution constituting the accepted key thought, yet nowhere stated. In these articles suggestions of control and compulsion should be minimized.

Since so many foreign-speaking people do not read, it might be well to employ some pensioners and disabled men as conversers, talkers—the functionary corresponding somewhat to the Jewish schnorrer, to go among the men and subtly talk the harmfulness of accidents.

But the larger field for personal and oral presentation will be lectures and demonstrations. Very efficient use has been made of lectures, illustrated and non-illustrated. Let me suggest that the method be varied occasionally by introducing a brief lecture unexpectedly into a program arranged on a basis of entertainment solely. Thus you will secure a little of the time and thought of the indifferent. Such a lecturer, remembering the lack of interest of most of his audience, will do well to speak briefly, epigrammatically, making use of catchy, easily remembered phrases.

On the market there are now several automatic projection machines which makes it possible to use still life pictures to advantage if their pictures and texts are frequently freshened and if

the location of the machines are changed occasionally.

Occasionally advantageous use can be made of talking machines; for instance, short talks by Judge Gary, Mr. Rockefeller, Lloyd George, President Wilson, and the presidents of great corporations would prove effective.

Expositions, museums, and kindred methods are of service in educating employers, as well as museums of safety and other permanent exhibits, such as the display in the rooms of the Illinois Labor Bureau. Hazardous machines with dangerous parts advantageously may be set in rest rooms.

So much for the education of adults which is always a difficult thing to do, and expensive, and wasteful.

Education of Children

The education of children is a far more satisfactory field. I have read with interest "Education in Accident Prevention" prepared by Dr. E. G. Payne upon request of the National Safety Council. It is a guide book for teachers. In other words, it may be considered an excellent work for the education of teachers in the teaching of accident prevention. The United States Public Health Service and various state boards of health have prepared text-books on health subjects to take the place of ordinary readers. As I understand it, none of these has ever come into very wide use. Teachers have explained to me that they must use the adopted text-books, and no book agents ever attend the meeting of the adoption boards to secure the adoption of these free health readers.

If you go into the text-book field there is but one way to do and that is to play the game as it is played. It might be advisable for you to consider cooperation with the health people in the production of readers, spellers, and other texts making use of such stories as you could furnish as material for the books.

There is a general agreement among teachers that teaching should deal more with the experiences of the day. Even first and second readers would be more interesting if they carried some experiences from the workshop and the home rather than many of the stilted, far away stories now carried. When you get into this field, if you do, play the game as it is played.

Accidents on Economic Basis

Payne says that while industrial accidents are limited very largely to adults, the same is not true of public accidents. In 1916, 10,534 children under ten years of age in the registration area

were killed by accidents, with perhaps 250,000 others severely injured.

This is a good place to say that discipline is a most potent factor in the prevention of accidents. Childhood is the time to teach discipline.

Far and away the most potent educational influence of accident prevention was the passage of the workmen's compensation laws. The placing of accidents on an economic basis was directly responsible for much of the result. A great part of its effect came through creating a background for the National Safety Council and its superb educational work. Thus indirectly and directly workmen's compensation was responsible for the "Safety First" movement. Personally, I would like to see the application of the same principle to prevention of accidents in fields other than in industry, and in the general prevention of disease.

Eight-Hour Working-Day for Sweden

The Upper Chamber of the Riksdag of Sweden on September 29 passed a bill providing for an eight-hour working day, the Lower Chamber having recently passed the same bill.

CANADIAN COLLEGE HAS EMPLOYMENT MANAGEMENT COURSE

The experiment of the University of Toronto in establishing a short course on employment management attempts to solve some of the difficulties of labor management.

The college will provide courses in personal management, industrial, psychology, and economic principles and methods. Two of the lecturers are Lieut. Col. John J. Coss, of Columbia University, and a member of the War Industries Board of the United States, and Dr. E. K. Strong, of the Carnegie Institute of Technology, Pittsburgh, and a member of the committee on the classification of personnel in the United States Army.

FATIGUE LOWERS MORAL RESISTANCE SAYS JANE ADDAMS

While emphasizing the importance of furnishing, especially to women workers, a stimulus to sustain them, Jane Addams, in a recent address before the International Conference of Women Physicians, discussed the psychologic as well as the physiologic side of fatigue. She says there is an appalling connection between excessive fatigue and delinquency.

The personal equation was brought out and a discussion of fatigue by Dr. Frederick S. Lee, of the College of Medicine, Columbia University, who declared that the eight-hour day will not solve the problem; that eight hours is too long for one job and too short for another; that working hours and suitable rest periods must be worked out for each job, and workers must be adapted to the labor required of them. The examination of 2,500 women factory war workers in England has shown 42 per cent to be suffering from excessive fatigue, which seems to emphasize that especially is it essential for women in industrial work to be physically fitted to what they undertake to do.

INDUSTRIAL CLINICS IN GENERAL HOSPITALS

BY D. L. EDSALL, M.D., DEAN, HARVARD MEDICAL SCHOOL, CAMBRIDGE, MASS.*

C LINICS in industrial plants for the immediate care of injuries and medical ailments have become of undisputed value and laws are being passed to require them. They need no argument now with those of open and educated mind and I have no need to discuss them as they are outside my personal field. The character and extent of the service that they will render may ultimately go far beyond what is now done in most plants, though this is of course a very debatable question since it is by no means certainly desirable, and because it conflicts with the established interests of medical practitioners. But, however far this may progress, for an indefinite time to come, if not always, general hospitals will be the centers for groups of experts in the various clinical and laboratory lines that are now essential in the diagnosis and treatment of patients and in the study of problems of health.

Individual industrial establishments can scarcely be conceived of as having each within their own employ a group of leading men in all the various lines of clinical and scientific medicine. Hospitals, particularly those connected with medical schools and with the staffs that the latter have, will always, therefore, need to be centers for the study and treatment of difficult cases and for the investigation of problems, however far health establishments in industrial plants may progress.

Industrial Clinic a Necessary Adjunct

At the present time, however, the general hospitals receive and they will long continue to receive not only complex cases but the every day routine sort of case for ordinary diagnosis and treatment, and they have in their clientele, all told, a greater number of industrial workers than any other organized establishment for the care of the sick. In performing their simple daily round of duty, as well as in acting as consultation centers, the hospitals cannot give proper service

The industrial clinic furnishes sources of new knowledge and opens the way to studies in new directions through an accumulation and analysis of records based on diseases and injuries of industry.

A second noteworthy feature of the industrial clinic is the relation possible between the clinic and medical schools and the opportunity to train students into an appreciation of the place of medicine in industry.

Although not a separate science, but a work based upon various sciences, the study and recognition of the hazards of industry and their effects are a clear cut and well defined type of work.

unless they have on their staffs persons familiar with industrial hazards and their results, who will be alert to recognize these and capable of determining their importance or insignificance in individual cases. Let us contrast this matter with others that are comparable.

No hospital is capable of giving what is now recognized as good diagnostic or therapeutic service to patients with

infectious diseases, for example, unless it has available the men and the equipment for expert bacteriological work any more than it could give good surgical care without surgical equipment and expert surgeons.

Although not a separate science like bacteriology, but work based upon various sciences, the study and recognition of the hazards of industry and their effects are a clear cut and well defined type of work. Its problems are quite as definite as those of bacteriology and, while they are even more varied and complex, the nature of many of them and the method of attack upon them are clearer and in expert hands more likely to be successful.

Industrial Origins of Disease

The possibility of an industrial origin of health disturbances and the need of determining this point comes up, too, in the great bulk of the hospital clientele; in fact, its possible importance needs to be considered in a far larger percentage of cases than does any other health factor. In the first year that our industrial clinic at the Massachusetts General Hospital was so organized that it received the greater part at least of those patients who might be suffering from effects of industry, and in whom this needed to be determined with care and through trained and intelligent inquiry, more than 5,100 persons were sent to this clinic for investigation; of this number

*Read before the Eighth Annual Congress of the National Safety Council, Cleveland, O., October 1-4, 1919.

approximately one-tenth showed actual results of their work that were at least of noteworthy, and often of dominating importance in explaining their ill health. In most of these instances, the question could not have been settled and, in those in which there was a relation, the connection would have been overlooked had the investigation been done in the customary way by persons who had not accumulated interest in and extensive knowledge of the possible relations of the patient's job to his illness.

This is clearly shown in our experience in that time in lead poisoning. A special search was made for lead poisoning in all persons in whom careful inquiry showed any exposure to lead. Ordinarily the poisoning is looked for only when either the hazard is obvious and commonly known or the symptoms clearly suggest it. The difference in method had the result that the same number of lead cases were found in one year by special search as were diagnosed in five years by the ordinary methods and this in the same clientele coming from the same general line of industries.

Specific Trial Convincing

A considerable trial of a special industrial clinic in a general hospital and of other less well defined methods of attacking the problem of the relation of industry to general medicine has convinced me that no other method than a special clinic goes so far to insure good service to the patients and no other method so stimulates and enlightens the interest of the hospital staff in general in this important health factor. Likewise, by no other means is it possible to group the cases together in such manner that the results of study can be analyzed and made available, and in no other way does there occur such an accumulation and repetition of experience as to make evident and important problems that had been unrecognized or had seemed of little significance.

To be really useful and successful, several things appear to be necessary. The clinic should be in charge of a physician whose greatest interest is in the work, and he should be on sufficient salary to enable him to spend most or all of his time at the work. This is necessary in order that he may properly develop his clinic and may be free to make visits to factories in order to accumulate constantly increasing knowledge of industrial processes, and in order to determine day by day whether in doubtful cases seen in the clinic the work really explains a part or the whole of the effect upon health. Much of his time will be needed also in making studies in the clinic,

in factories, and in the laboratory of the problems that are frequently suggested; and in this he will have many opportunities to keep occupied voluntary or paid assistants.

The Social Worker an Aid

Another essential element in the clinic's success will be a trained social worker who is familiar with factory conditions and industrial processes as well as with general social conditions. Through her will be best handled many of the social details of the records and she will be able to investigate both home and factory conditions in order to provide the essential knowledge of the relative bearing of the home and the factory upon the health of the patient. Such a small paid staff is necessary for success. From this it may easily be enlarged with voluntary or paid workers as occasion demands. Furthermore, a method must be adopted which will make sure that all cases with interesting or suggestive industrial relations get to the clinic. It will not suffice to depend upon those in the medical, surgical or other clinics for sufficient interest to refer cases either spontaneously or upon request. They usually do not recognize the hazard or its relation to the patient, and in the pressure of their work they frequently forget to send any that they do recognize.

We have with some success adopted the plan of having a social worker, who is sufficiently instructed in industrial hazards to serve in this way, stamp the cards of all new patients as they enter if their occupations come within a list furnished her or if they otherwise seem interesting. Whatever other clinics they go to, they must when so designated go also to the industrial clinic before leaving. The other social workers in the various clinics are also instructed to send to the industrial clinic any cases showing points of interest in relation to industry. Cases that are primarily of industrial interest, especially certain groups that are being particularly studied in the industrial clinic, are transferred to that clinic for regular care; others are simply referred for diagnostic, therapeutic, or preventive advice while their management is continued in the other clinics.

Carried out consistently in this way, the clinic will, in any large out-patient department, have abundance of material both to provide wide experience in industrial effects upon health and, also, for study of the problems that local industrial activities furnish. Some of these problems will be already known; some will become apparent from time to time as a large number of people pass through the clinic and the possible relation

of a job to a disorder becomes emphasized by repeatedly meeting the possibility.

The Value of Such a Clinic

The primary value of such a clinic has been, in my mind, the better care of the patients. Equally obvious are the opportunities for furnishing new knowledge and thus improving conditions through carefully planned studies and through accumulation and analysis of records.

Likewise important to a hospital that has relations with a medical school is the opportunity to train all students into an appreciation of the relations between varied industries and medicine, and to give special and detailed training to undergraduates or graduates who wish to become especially qualified in the medical service of industry. The latter students can be given thorough knowledge of a limited number of hazards through serving temporarily in one or more plants. In no other way, however, than in such a clinic can they so well be given a comprehension of the extremely numerous and varied things they should be prepared for and then have opportunity to observe in factories a considerable number of these types and the methods of controlling them. By serving with the staff in the industrial clinic, and in the factory visits the clinical work leads to, they obtain a wide general training in elementary knowledge of these things that otherwise would be obtained only slowly, laboriously and unsystematically.

The Wide Range of Benefits

Beyond those mentioned, however, we have found other not unexpected sources of interest and helpfulness arising through the clinic. Diagnoses made in individual cases or advice given to the patient have often been transmitted to the employer with the result that he has thereby first recognized the existence of that hazard in his plant or first seen how it may be controlled. Employers have frequently extended the advice to cover all those exposed, have investigated conditions not previously studied, or have sought further advice from us or from others on the problems involved. This has been especially true of the small employer who has but slight or no health service in his establishment, but it has repeatedly occurred with large plants.

Labor unions have also at times come to us for health advice through some of their members having been in the clinic. Fairly and tactfully carried out, the relations with labor unions may be made very useful in furthering industrial health, among other reasons because a clinic in a general hospital is obviously not subject to the

suspicion with which the unions unhappily often have regarded the health service in their own industry.

The Impetus to Research

The largest possibilities of useful development lie, however, in the research that can be carried out if the clinic acts as a center for coordinating the problems that are unearthed in it with the health and technical departments of the industries, on the one hand, and on the other, the men and facilities that are found in medical schools and hospitals. There are among these two groups and their equipment the possibilities of attacking all sorts of problems and, not infrequently, of solving them. Research developments that will control or do away with hazards are, of course, in the long run far more important than the diagnosis and treatment of a group of cases, important as the latter is.

In the past several years cooperative studies of blood problems, problems in pure physiology, problems in metabolism or in biochemical matters, toxicological problems, problems of general hygiene and sanitation, and others have appeared desirable as a consequence of observations in the hospital clinic. Some of these have been carried out with our colleagues in the medical school and hospital in spite of the heavy pressure of war conditions.

Industrial Surgeons Aid Studies

Studies have also been made in cooperation with physicians in charge of large plants and several corporations, some of them very large, have offered the cooperation of any portion of their research departments in working out the technical industrial end or the engineering aspect of some hazard, the existence of which observations in the clinic had suggested. In this way as in most others our clinic, as well as our whole method of attack upon industrial medicine from the hospital or the academic standpoint, is really in its infancy; but progress thus far seems to open a vista of real public service if the varied departments of hospitals and medical schools can develop cordial cooperative relations with the health departments and technical departments of industries. Unlimited possibilities of good results with satisfaction and credit to both sides seem open and the problems and the opportunities for interesting and serviceable work grow constantly as one studies the matter.

"Training Courses in Safety and Hygiene in the Building Trades," is the title of Bulletin No. 31, issued by the Federal Board for Vocational Education, Washington, D. C. The booklet contains 126 pages.

THE SCOPE OF THE PHYSICAL EXAMINATION IN INDUSTRY

BY C. D. SELBY, M.D., TOLEDO, OHIO, FORMERLY CONSULTING HYGIENIST, UNITED STATES PUBLIC HEALTH SERVICE*

INDUSTRY exists solely for the purpose of converting raw materials into finished products of marketable value. Labor is employed in industry for the assistance it is in the accomplishment of that purpose, and its value is fixed by the skill and facility of its effort in that direction as manifested by the quality and quantity of its output.

Formerly, when labor was plentiful and the margin between the cost of production and a moderate selling price was sufficient to bring a reasonable profit, industry gave but little concern to labor. Workingmen came and went as they saw fit, were hired and fired as suited the fancy of their bosses, or were let out in dull seasons and taken on again when business improved. No well-thought-out attempt was made to offset destabilizing influences, and practically none to improve skill.

More recently, when labor has become relatively scarce and the cost of production higher, industry has been forced to realize that it has a problem in its labor relations; in fact, industry concedes this to be among the serious, if not the most serious, of its problems. Though old in existence, having been ignored, it is relatively new.

Employers do not yet know how to solve this problem. They are groping. They have created welfare departments, employment, service, and sociological departments, have sought to amuse, edify, and pacify the working people, have divided profits with them and have appointed them to act on joint committees in the determination of policies—with little effect as indicated by the present unrest, the greatest the world has ever known.

Employers are still groping, and they are progressing. Labor turnover has been studied, absenteeism investigated, and the cause of spoilage and breakage sought. Information of value has been gained. It has been learned that the most

The physical examination has become an important element in the science of modern industrial management. It is fundamental to the successful practice of industrial management.

The physical examination is the means whereby physicians acquire the information they deem essential to the procurement and maintenance of healthy, physically competent, workers. It is the basis of medical knowledge in industry.

The procurement of health and physical competency among working people requires that they be assigned to such jobs as they are or can be adapted to, with rejection as a last resort.

such workmen; if unable to procure them in the usual way, to develop them; and, having them, to retain them by offering favorable working conditions and opportunities for further development and advancement.

Physical Adaptation to Job

The procurement of healthy, physically competent workmen may imply the rejection of those who are not so. However, it does not necessarily follow that such should be rejected outright and deprived of the privilege of gainful occupation. There are positions in industry, in fact, in virtually every plant of reasonable size, that people of varying sub-standard conditions of health and body can fill with efficiency, to the profit of their employers and themselves. For example, defective eyesight may justly disqualify a man from operating a machine that requires acuity of vision, yet permits him to supervise a gang of laborers with competency. Again, a chronic bronchitis may render employment in a foundry hazardous and unprofitable, while in the open it may have no detrimental effect. Even the blind and the legless, the tuberculous and the nephritic, are capable of productive labor under proper conditions of employment. Only the manifestly unfit and the victims of communicable disease should be rejected, is a growing opinion among employment managers. The procurement of

*Read before the Eighth Annual Congress of the National Safety Council, Cleveland, October 1-4, 1919

health and physical competency among working people requires that they be selected for and assigned to such jobs as they are or can be adapted to—with rejection a last resort.

The maintenance of a healthy, physically competent force of employees requires that working conditions shall be such as to safeguard health and limb, that workmen shall have knowledge of how best to live and labor in compliance with the laws of health and safety, and that health and limb shall be restored as promptly and effectively as possible after impairments or disease have occurred.

The service of physicians, originally sought for the treatment of injured workers, has been found to be of use in the procurement and maintenance of healthy, physically competent working forces. Medical knowledge and skill are, therefore, welcome to industry, for anything that is capable of assistance in the stabilization and improvement of working forces is welcome. Because of this, medicine has come to be an important branch in the science of modern industrial management.

Examination Advantageous to Men

The physical examination is the means whereby physicians acquire the information they deem essential to the procurement and maintenance of healthy, physically competent working forces. It is consequently the basis of medical knowledge in industry and is fundamental to the successful practice of industrial medicine.

The scope of the examination should be broad enough to enable physicians to gather the information that is requisite. This means it should uncover defects and diseases that render employment hazardous to him who seeks it or to his fellow workmen. It should uncover imperfections that contribute to inefficiency. It should uncover diseases and sub-standard conditions of health. In short, the examination should be such as to divulge the true condition; it should be fairly comprehensive.

Although a complete physical examination, with blood pressure readings, urinalysis, and other laboratory tests, is a desirable procedure to follow in industry, it is not always practical. In the first place, industry has not found it necessary except in unusual cases and, in the second place, industrial physicians are usually too pressed for time to investigate deeply. Experience has gradually evolved four grades of examination, depending upon the objective sought, which in turn is frequently fixed by the policy of the company concerned. They are as follows:

(1) *Superficial Inspection*—This consists of a hasty survey for obvious defects and appar-

ent sickness. It considers height, weight, appearance, deformities, distance vision, hearing, hernia, and occasionally the heart and lungs (stethoscope applied outside of shirt). Its objective is *rejection* of the evidently unfit and exclusion of communicable diseases.

- (2) *Inspection*—This consists of a more complete survey. All parts of the body are exposed and their condition noted. Diagnostic instruments are used when in the opinion of the physician they are needed. This is practically an examination—without urinalysis and other laboratory tests. Its objective is *selection and assignment* of workers.
- (3) *Examination*—This consists of a reasonably complete survey of the body according to accepted methods, and includes blood pressure readings and urinalysis. It is virtually the same as the examination required by life insurance companies. Its objective is not only the selection and assignment of workers, but their *health supervision* as well.
- (4) *Special Examination*—This consists of all measures that are necessary to a thorough study of the body, including intra-ocular observations, gastric analysis, rectoscopy, cystoscopy, x-ray interpretations, investigations of the nervous system, blood counts, etc. Very few industrial physicians are prepared to make such elaborate and painstaking examinations. Individuals needing them are usually referred to consultants. The objective of the special examination is the *diagnosis* of obscure diseases and pathological conditions. It belongs rather in the realm of internal medicine than to industrial clinics.

Inasmuch as by far the greatest number of occasions for investigation into the physical state of industrial workers occur when they seek employment, the inspection would appear to be the most useful of the four grades. It has the advantage of gaining enough information to enable physicians to eliminate the manifestly unfit, if desired, to advise intelligently in the assignment of others, and to do so with a minimum expenditure of time. Furthermore, it secures enough information for physicians to determine which individuals must have additional study in the form of the examination or special examination, for the intelligent supervision of their health.

A Plan in Operation

To exemplify the author's conception of the scope of examination or, more properly, the inspection, the routine in use at the Toledo plant of

the National Malleable Castings Company is outlined as follows:

The worker is received fully clothed and remains standing until the feet are inspected. He is greeted in a friendly manner, and attempts are made to put him at ease if he is embarrassed or backward.

1. As he enters, gait, carriage, and appearance are observed.
2. He is weighed and measured for height.
3. Vision, both near and far, is tested.
4. The right ear and right side of head and neck are inspected. While this is being done the hearing on that side is estimated by a question in a low voice.
5. This procedure is repeated on the left side.
6. The face is inspected; the condition of the eyes is noted by lifting and depressing the lids; the nares, the mouth, and teeth, then also the throat and the anterior surface of the neck, are observed. The worker is requested to remove all clothes from the waist up.
7. The chest is inspected, and the condition of the heart and lungs estimated by percussion and auscultation.
8. The abdomen is inspected and the condition of the organs estimated by palpation and percussion.
9. The back is inspected and the posterior aspects of the lungs estimated by percussion and auscultation.
10. The spine is palpated and flexed.

The worker is requested to loosen his trousers and undergarments and let them fall around the ankles.

11. The external genital organs and inguinal regions are inspected and palpated.
12. The sacro-iliae articulations are examined and the anal region inspected.
13. All extremities are inspected, mobility of joints and condition of blood vessels being especially observed.

The worker is now requested to draw up his underclothing and trousers. Next he is directed to sit down and take off his shoes and socks.

14. The ankles and feet are inspected. If there is any doubt about the arches, impressions are taken.

15. Blood pressure readings are taken (optional).
16. A specimen of urine is obtained (optional).

The worker is now dismissed. During the inspection as defects appear, the physician is expected to inform the worker of their presence and to give him such advice as may seem wise, an interpreter being used when needed. Special features are emphasized immediately before departure and further advice given if necessary to enable the worker to do his work without hazard to health.

Benefits to Worker Test of Adequacy

In commenting upon this procedure, it may be said that inspections by this method may be made superficial or thorough, as desired, with minimum expenditure of time and effort. The inspection moves easily, without offense, from the exposed parts of the body to those the blunt exposure of which can prove embarrassing to the worker. It meets the requirements for job placement, and prepares the way for subsequent examinations essential to the supervision of health. When ac-

accompanied by appropriate advice, when the information obtained is properly used in assignments to work, and when those found defective are afterwards helped through medical and social service and continued advice, then the inspection contributes to the health, earning power, and peace of mind of the workers, and its scope may be regarded as being adequate.

In some establishments applicants for work enter the examining room stripped. If this can be done without offense, the physician's time may be thereby economized to the extent consumed in undressing and redressing. This is an advantage where large numbers are hired, but the tendency of physicians, speeding from one to another, is to slur the educational feature, which is of exceeding importance. On the contrary, if the doctor is forced to wait, he has the opportunity to discuss with the workers their conditions and, therefore, has no real excuse for not doing so.

That which has been said applies to the inspection of men. The inspection of women is quite another matter and, although the same general plan may be followed, considerable tact and discretion must be used. The thoroughness of the inspection must frequently be dictated by discretion, and it is wisdom always to have a woman nurse present. Good judgment really indicates that women should be inspected by women physicians.

Points Required in Record Forms

For the further exemplification of the author's conception of the scope of the inspection, a form¹ which has been devised for recording the information is presented, as illustrated. This form has been evolved from experience in the physical inspection of school children, the inspection and examination of applicants for employment and from studies during the war of industrial medical departments and the forms used in sixty-four of them. The form will not be described as, with the exception of the code at the top, it is self-explanatory. The code, it may be said parenthetically, is a part of a plan in use at the Toledo plant of the National Malleable Castings Company for determining the kind of operation for which an applicant for work is physically fitted. A description of this plan and an explanation of the code is not appropriate to this discussion. The principal advantages of the form are as follows: (1) it provides for specific mention of conditions most usually found providing also for the recording of unusual conditions; (2) it records finding practically in the order of inspection and indi-

cates at a glance the side of the body involved; (3) it permits recording with a minimum of clerical effort; (4) it permits tabulations and compilation of reports with a minimum of medical knowledge and clerical effort; (5) it permits diagrammatic representations of abnormalities and amplified description of special features; (6) it permits the recording of three subsequent inspections in direct comparison with the original; and (7) it has a wide range of adaptability in the recording of information secured by means of any of the various grades of examination, except the special examination.

Looking Toward Standardization

In the use of this form, the physician may himself register his observations or, better, he may memorize the numbers and indicate to his clerk the findings by their number. The latter method is of course quicker and easier for the doctor.

It will be said in closing that neither the procedure for physical inspection, as outlined, nor the form is regarded as final or conclusive, or in any sense a finished product. Minor changes and additions are constantly being made in both as experience indicates their need. They have been presented primarily for the purpose of exemplifying the author's conception of the scope of the physical examination in industry. It is hoped, however, that their presentation may stimulate this organization to take further steps toward the standardization of the examination and the form, and a promulgation of a better conception of the relation of the examination to industrial medicine and of that to the needs of industry and labor.

INDUSTRIAL ACCIDENTS AND HYGIENE

In the July issue of the *Monthly Labor Review* appears an article by Alice Hamilton, M.D., discussing occupational diseases in Pennsylvania. She takes up in order industrial poisoning from lead, carbon, monoxid, brass, mercury, arsenic, various industrial gases, and coal tar products. There is also a discussion of diseases caused by physical agents in the textile industry, in coal mining, and the importance of anthrax as an industrial disease.

There is no compensation for occupational diseases in Pennsylvania. While in this respect some other states are more fortunate, the advantage is somewhat lessened by the difficulty of actually proving the occupation to be responsible.

"It is true," says Doctor Hamilton, "that we are learning each year more about the action of various poisons on the human body and also of such indirect factors in the cause of disease as fatigue, heat, and humidity; nevertheless, we can connect occupational disease only in a small number of cases with that degree of positiveness that would be required under the law. . . . No law, no matter how wide its application, would ever cover all cases of occupational diseases."

¹. One side only of this form is reproduced on the opposite page. Diagrams of the human figure with numbered sections are printed on reverse side of original form.

MALINGERING—INVOLVING THE PROBLEM OF GETTING SICK OR INJURED EMPLOYEES BACK TO WORK

JUDSON C. FISHER, M.D., SPECIALIST IN INDUSTRIAL INSURANCE, NEW YORK CITY*

MALINGERING may be defined as the feigning of illness or injury, or as the exaggeration of symptoms. Some comparative zoologists after studying the animal kingdom, say that malingering is a form of self preservation—an offshoot of fear. In the animals it is called instinct. If one stops to analyze the cases of malingering in respect to nationality, physiognomy, and mentality, there are evidences that this "instinct" is a real thing, and a trait which supports Darwin's theory of evolution. History and literature have recognized malingerers since the beginning of the world. The earliest instance known is recorded in Genesis¹ when Rachel, in 1056 B. C., maledgered in order to secrete the stolen idols of Laban. What boy in our day has not maledgered in order to attend the ball game, carry water for the elephants, go fishing, or escape an unprepared lesson? While the problem is old, yet in these fast moving days of industrial activity there are new aspects which must be considered. The various methods of malingering, the tests for its detection, and the training of the doctors for this special branch are material for later papers.

That admirable legislation known as the Workmen's Compensation Act, now operative in the majority of the states, has given us opportunity to study closely the injured employee, and, where occupational diseases are included, has stimulated interest in the sick employee.

Malingeringers in the Minority

In justice to workmen in general, I believe malingeringers to be in the minority. The ideas brought out in this paper are for the purpose of detecting and curing an ulcer which causes the innocent to suffer and by its cure will cause the honestly disabled employee to receive all the honor, sympathy, and consideration due him.

The malingering employees may be roughly

SOCIETY THE MALINGERER'S PREY

Society is conceived by the malingerer to owe him something. His mental quirk exaggerates his wrongs, minimizes the rights of others, and makes him a fit subject for bad suggestion and for vicious leadership.

The real remedy is in the physical examination which eliminates the mentally unfit, and in educating the workman to a sense of his responsibility to industry, and to a proper spirit of loyalty.

The present safeguard is to be found in an administration of medical service that will check the fraudulent claim at the outset, and provide such penalties as will minimize the abuse.

classed as: (1) dishonest employees who say little, and (2) exaggerating employees who are less experienced and therefore vulnerable to make the most of their injuries.

The dishonest employees or "fakirs" are those who have a slight or no accident or illness. They report an injury and become immediately disabled. The doctor finds little or nothing on physical examination, but, willing to be always

fair, gives the employee the benefit of the doubt and sends him home. His disability becomes total; on account of "pain," he says he cannot work. If he has a slight cold he reports sick and says the pain in his chest keeps him from work. Physical examination shows no evidence of illness.

The Urge to Malingering

Where settlements are permitted, as among stevedores under the Admiralty Law, foreign labor is urged and often assisted to malinger by the "runner" or "shysters." Within the last three months I have seen the following malingering cases of this class:

1. B. C., age 38, Italian, married. Was lightly hit by a draft of boxes and was supposed to have injured his left shoulder. He went to a doctor, who treated him every day. Physical examination three weeks from date of accident for the purpose of determining the extent of disability showed marked inability to raise the left arm and, upon palpation, a very tender shoulder joint. After various tests no signs of fracture or changes in or about the joints were discovered. There was a mottled blue area of skin about 4 inches in circumference over the shoulder. The "bruises" were superficial, and not deep. Investigation confirmed the suspicion that these "bruises" were caused by some one sucking the skin of the shoulder, and making what the boys call "fox bite." Had the man sustained a real injury, the settlement would have been in proportion and the "runner" would have had a larger fee. In this case the employee was dishonest and with the hope for greater benefits the "runner" tried to assist him to be more dishonest.

* Read before the Eighth Annual Congress of the National Safety Council, Cleveland, October 1-4, 1919.

¹ Book of Genesis, xxxi, 86.

2. P. Q., age 46, Hebrew, married. Claimed to be walking along a warehouse when he slipped on a banana peel. In trying to catch himself he bent backward and hit his head and the middle of his back upon some crates standing near. No one saw the accident, but a doctor strapped his back. When examined there was a blistered area of skin across the small of the back which proved to have been made by a hot poker in order to fool the examining doctor. While his back was being examined, his clothes were dropped down about his ankles and his hat placed upon the floor. During the examination he claimed inability to bend forward. Upon being left alone he was seen, through a peek slit from another room, to bend over, pull up his clothes, and pick up his hat.

Flagrant Dishonesty Employed

Flagrant malingering, when the claimant is dishonest, unassisted, is seen as in the following cases:

1. M. N., German, age 22, draughtsman. Was injured in Niagara Falls. He claimed that while lifting one end of a drawing board he felt pain in both groins. Physical examination showed a large indirect inguinal hernia on both sides. He claimed never to have had a lump on either side before. He insisted upon operation by his New York family doctor, and not by the insurance company's doctor. His doctor used carbolic acid in mistake for novococain, burned the skin from the boy's navel to his knees and he became sterile by the contraction of the scar tissue over the cords. Investigation showed that the drawing board weighed twelve pounds and his end, therefore, weighed six pounds. The condition could not have been traumatic hernia. This malingering caused loss of services and money to the employer, and much suffering with permanent disability for the malingerer.
2. M. M. Was led in by a young girl. He stated he was 51, married, family in Italy, and that he had been burned in both eyes by live steam. He claimed to be able to distinguish light and dark only. External physical examination seemed to bear this out except for the fact that his eyes quickly followed the dropping of a ring to where it rolled. While he was faced toward the window his coat was put on another chair, his hat hung in a darkened corner of the room, and his glasses changed to another position of the desk and partially hid by a paper. His ability and agility in finding them while talking about compensation led to the rejection of his claim.
3. A young man, formerly an acrobat, age 28, married. Sprained his ankles while carrying a heavy chain. He returned to work in three weeks; compensation was paid and the case evidently closed. He apparently did the same and heavier work for nine months. Then he laid off and asked for a re-hearing. Physical examination was negative, x-ray was negative, yet he held his feet almost rigid. Several doctors, including the chief surgeon of an accident board, could find no cause for his complaint that "the pain in his ankles was so bad he couldn't work." I couldn't elicit the usual evidences of pain, and finally had him kneel in a chair, facing the back. His feet hung rigidly. Tapping the Achilles tendons caused an unexpected free extension of the feet. This movement was not painful. This was one of

the very few cases where I felt justified in testifying "this man has no pain." Despite the negative evidence the board awarded compensation. Leaving the building the employee said to me, "I guess I didn't talk up to them enough. S. told me that he talked up and was given \$3,000 and I got less than \$1,000." After the settlement he had no further need for his cane.

The second class is composed of employees who have been ill or injured so that the evidences are present upon physical examination, and yet who claim to be unable to return to work. In these cases the physical examination shows exaggeration of symptoms. The men decide not to return to work until they are as "fit as the day they quit." This class may be divided into (1) those who are in the age group 25 to 40, and (2) those who are in the age group 55 to 75.

The age group from 25 to 40 contains many malingererers who desire time off because, when idle, they make more money. Such a case is that of J. C., as follows:

J. C. belongs to several lodges or mutual benefit societies, whereby the total weekly benefits, including compensation, exceed the average weekly wage. His wife may also be working and adding her mite. In these days of high wages and comparatively low compensation benefits this class has fallen off in numbers, but in ordinary times these employees we always have with us. The men find it much easier to have free medical attention, to have high weekly benefits, and to be able to sit around and talk or read, than to have to work in order to earn the amount sufficient for their needs. This is especially so when the earning power is less productive than the benefits.

Age Groups of Claimants

The age group from 55 to 75 years—the winter season of life—usually contains men who own a little property purchased with their savings and have rent practically free. They have children who are married, and any at home usually contribute, so that the income from compensation boards, lodges, and members of the family, with an occasional gratuity from the employer, is more than sufficient to feed and clothe the family. These men are satisfied to sit around and talk and do the chores; but when it comes to work they claim inability of all sorts. A good example of this class resides in the city of Buffalo. His history is as follows:

K. K., age 62, married, no children. While working for his brother as a carpenter, fell a distance of ten feet and landed on both heels. He fractured both heel bones. The injuries were promptly and properly treated. The slight swelling of the legs, common to inactive men of his age, appeared occasionally, and there was a slight deformity due to formation of callus in the left heel. He was fitted with proper arch supports and shoes, baked and massaged, and, after a period of total disability for fifty-two weeks, was told to return to work. The brother-employer was approached concerning re-employment of K. K. He said he thought K. K. should rest and thereby prolonged

the disability because K. K. would "work for nobody but his brother." K. K. claimed pain in the muscles of his leg after standing a while, and pain in the bones of his feet at night. He refused to try to do anything. Five years after the accident the examination revealed nothing more than the usual results of this type of fracture. Investigation proved that he owned his home, did the chores, cut the grass, cared for his garden, hoed the potatoes, and yet exaggerated his symptoms so that the insurance carrier has paid him \$15 per week for five years, with the prospect of paying him as long as he lives and the chance of supporting the widow afterwards.

Statistics show that more employees malinger who are injured than those who are ill. This is probably due to the legal liability feature; therefore, we will deal with our problem of returning the employee to work with a tendency toward the accident feature. Necessarily this will involve problems of workingmen's compensation administration.

Returning a Malingerer to Work

The problem of returning the injured or sick malingerer should be attacked as the medical profession attacks diseases. The premise is that the disease is present. To treat it properly there must be a knowledge of the causes, the symptoms and signs of the illness itself, and the cure by (1) preventive measures, so that others will not be afflicted, and (2) the treatment of the diseased one by eradication of the symptoms.

As to the premise there is no argument. No sane person doubts its existence. The causes of malingerer are many, and because of their importance in treatment they should be mentioned in order.

Starting with the malingerer himself, we must consider him as to his age, sex, education, and mentality. Among foreign elements, especially the Latin races, all ages tend to exaggerate and malinger. The American youth, except in rare instances, wants to be back at work as soon as possible. His future is before him. About fifty years of age man begins to consider work as a means of existence and takes pride in his past achievements. He begins to feel that society owes him a rest and a pension, and exaggerates accordingly. Some older men, with the pride of years of service behind them, will drag themselves to work if possible that their record may not be broken. Men with such spirit are the real heroes of labor. Unfortunately, human nature seeks rest as the sun of life sinks.

The influx of women workers during the world war is too recent for reliable statistics. It would seem, however, that their ambition and ability to endure would result in far less malingerer in proportion than among the male sex.

The less educated, the more lazy. Conversely,

as the mind improves its status so does the malingerer become lessened. There seems to arise an ambition which refuses to be downed by ill luck. Therefore, lack of education is recognized as a cause of malingerer.

The mental attitude of the employee is interesting on account of the motives discovered. (1) He may be revengeful and feel that his employer owes him more than the law provides, or that the prolongation of disability will tend to get even with the employer for some real or fancied wrongs. (2) He may be ambitious for attention, sympathy, and alms. All clinics have those who make regular rounds year after year. The hospital charity organization societies, churches, lodges, and various benevolent societies know this type well. (3) He may be defective mentally. That type includes the fanatics, the convulsionists, the hystericals, imitators, and manic-depressive cases.

Employers as Extremists

Employers may be divided into two classes for our purpose. One class is composed of those who are too generous. They pay full wages for time lost irrespective of compensation laws. In some few cases this would be extremely gracious and well deserved, but in the vast majority of cases the temptation of nature to prolong disability is too strong. The other class is just as close and indifferent as possible. While I was trying to induce a president of a large concern to introduce a sanitary lunch room, hospital, and first aid organization, he said: "Why should I try to make it pleasant and safe for those fellows aside from my question of rate? The whole 5,000 would walk out tomorrow and not think about me if an agitator trumped up some fancied wrong."

Had he paid more attention to the comforts of the men, organized safety first units, taken the trouble to learn the names of a few men, dropped a smile or word of commendation here and there, or built up a brotherhood among the employees, there would have been little economic loss through malingerer. Personal interest, properly exercised, breeds loyalty among employees that even instinct can't abuse very much. Keeping the employees informed as to statistics of work in past years for comparison, and accident frequency with loss in terms of sick or injured days, will go far to arouse an indomitable pride in the workmen's heart. A lack of interest on the part of the employer means a lack of proper follow-up methods, and does much to favor malingerer.

Industrial accident boards foster malingerer by: (1) Having no facilities for quick hearings in

malingering cases as soon as detected. In some states it takes from two to six weeks to have a case appear on the calendar after application for hearing has been made. If detected, the malingerer knows he will be given consideration at least to the date of the hearings, giving him added weeks of benefits, which he otherwise would not receive.

(2) Urging legislation, raising the amount of compensation indiscriminately. The man with a sore finger can do work of some kind while the man with a broken leg can not get out to look for it. The helplessness of the latter requires greater expenditures and should have a higher rate. In other words, a scale depending upon the degree of disability should be chosen. The simpler injury, or the undue prolongation of an accident in like proportion calls for less in benefits. The most worthy should be entitled to the maximum benefits. Malingering is fostered by high benefits.

(3) Mixing politics and sentiment with business. Very few who appear before various state boards have failed to see an elaborate staging of a case with relatives for supporting parts in order to sway the Board. The sympathy thus aroused may cause a ruling not upheld by the higher courts. Union cards and political affiliations are worked to the limit, because the Law says that the Board shall be the sole judge of fact. With proper "introductions" the malingerer is confident that the Board may be generous.

(4) Failure to prosecute perjurers or malingerers when so proved. This freedom from prosecution is a source of comfort to the malingerer. What has he to lose?

(5) Failure to have a competent medical member of the Commission, whose duty would be to arbitrate all medical cases. He would weigh the opinion of the chief medical examiner against the testimony of the insurance company's doctor, or the claimant's doctor. Malingeringers could not then trust to the ignorance of a lay mind concerning the importance of the medical problems involved, or the symptoms presented.

Medical Profession and Malingering

The medical profession, sad to relate, contributes much toward malingering.

(1) Family doctors depend upon the families and their friends for their practice. They feel they can't afford to get on the wrong side of any fence, consequently the malingerer preys on them for certificates of extended disability which the doctor can later usually back up with some kind of opinion.

(2) Lodge and society doctors are in the same class and their reappointment the following year depends on the vote of the lodge. These doctors rarely perjure themselves for a few dollars, but they will stretch the truth. Malingeringers get certificates with comparative ease from such men.

(3) The shyster doctor, as well as lawyer, we have with us. To such the truth means nothing and they trust to their personality to convince lay board members of a fearful and wonderful condition in the claimant. This type of doctor has his "price."

(4) Incompetent doctors, treating all manner of eases, prolong and sometimes provoke disability unduly, and discourage the injured or sick. Thus they encourage malingering.

Combination with "Third Party"

The so-called friendly enemy or runner who learns a few symptoms of disability and how to produce them artificially in some cases. This party, plus a natural malingerer, makes a hard combination to beat. The runner is after his percentage and the higher the cost to the employer, the greater his profits.

The detection and methods of detection of the signs and symptoms of malingering will be left to the industrial surgeon or specialist in malingering. Suffice to say that the diseases having been proved present, we next consider the treatment.

Preventive or Prophylactic Treatment

This consists chiefly in correcting or removing the causes.

As for the employee; pension the faithful employees before they are added to the industrial scrap heap; stimulate pride in men to outdo the women in stick-to-it-iveness. Educate them at least to an awakening interest; determine the mental attitude by physical and social examination before employment, and eliminate the mentally unfit. The moral and physical hazard of those employees in daily contact would be greatly increased if defectives were allowed on duty.

The employer should be kind, gentle, courteous, and jolly, but firm and not unwise generous. He should make the employees feel it is their business, also, and each man is a spoke in the wheel which will not run smoothly if a spoke is missing. He should advocate employees' clubs, comforts, and organizations, and encourage them with his occasional personal supervision.

The industrial boards should have one-day emergency calendars presided over by a commissioner who is a competent surgeon and a specialist in malingering; a fair scale of benefits so that the worthy receive their due; a high sense

of honor as custodians of hundreds of thousands of dollars of employers' money; an understanding that politics and sentiment must be minimized in relation to business and the law, and prosecuting or assisting the district attorney to prosecute, all malingeringers and perjurors so proved.

The medical profession will from now on contain trained industrial surgeons. Progressive colleges are beginning the courses. These should supplant the family, lodge, society, shyster, or incompetent doctor. These surgeons should be supported in industry, but should not be subservient to it.

The board and employers should refuse to discuss a case promoted by a runner or shyster lawyer. These vultures prey upon the laborer's ignorance of his rights under the law, and demand a percentage of that to which the law says he is entitled. There is no need for the runner, and he should be eliminated.

Active Treatment of Malingering

The problem resolves itself into the fact that these employees are lingering and loitering on the threshold of industry. How best to encourage their voluntary return? At the beginning of employment, the application blank should have these questions on it:

- (1) Have you had any previous accidents? Explain.
- (2) Have you had any previous illnesses? Explain.
- (3) Are you now in good health?

A malingerer is not necessarily a *good* liar, for a good liar remembers his previous story. There should be a careful physical examination before employment. Defects can be noted so that minor injuries cannot be amplified. Accidents or illnesses should be reported by some one within twelve to twenty-four hours after occurrence if they are to be considered. Employers should be protected by the law in this. A physician should make an immediate examination and control the case. Under such a procedure a smashed finger at home can not be charged to industry; a gonorrhreal joint can not be referred to a strain two weeks old, lumbago can not be called a sprain from work. Of course when particles in the eye give trouble next day, or infection sets in three days after a scratch there are definite signs of presumptive injury while at work.

Prevent by Proper Organization

The organization should provide a trained industrial surgeon who has specialized in malingering. He should have a pleasant and forceful manner, be a business man, and should be well read. He must have a convincing manner on the stand and have tact. He should have assistants, as

many as necessary, to treat all injured men immediately upon report of accident or illness, and to make thorough examinations before employment, and at any time it may be necessary.

Nurses are required who can pleasantly jolly a malingerer and, if possible, shame him into going back to work.

One or more social service nurses, male or female, are needed to check up and investigate any suspicious or questionable testimony. These nurses should have a claim training so as to know a few details which they could attend to when necessary.

System to Lessen Malingering

The following system to lessen malingering could be instituted. As soon as an employee reports ill or injured he has prompt attention by a doctor. The doctor's report, estimate of disability, and history of the case seen the previous day, is filed every morning. The employment card is attached to his history and physical examination card and becomes part of it. These cards or files go to a doctor for comparison. If the case looks legitimate, the treatment continues until disability from that illness or injury ceases. The file then is placed back in the filing system and the case closed. If the case looks questionable the facts are investigated by the social service department for inquiry and recommendation, and action taken accordingly.

If the claimant later tries to re-open his case, claiming all sorts of symptoms, he can be confronted with his previous well kept record.

If disability lasts over four weeks the case automatically goes out of the assistant's hands until the chief surgeon shall have made an examination and report. The chief's word is final—the man goes to work or receives further treatment, general, operative, or reconstructive. This gives also the advantage of the chief surgeon being able to watch the work of his assistants. At any time an employee is thought to be malingering the report should be made confidentially to the chief surgeon.

The scheme may be expanded into the realm of state medicine. It may also grow into a clearing house for information concerning dishonest employees, such as life, accident, and health companies support. When an employee is dishonest to the point of malingering, he should be known in order to prevent the honest employees being made to suffer by his actions. This would reduce the number of so-called "traumatic hernias" alone so that the saving in this one type of claims would pay for the bureau.

This scheme is also applicable to any group of

employers or insurance carriers in any one city where the individual system might be too expensive for any one employer.

Penalties Should Be Provided

A firm hand by the industrial boards in dealing with malingeringers is essential. It matters not whether benefits are cut off on the date the employee should have shown his good will and attempted to resume some work upon the physician's advice, or the knowledge that detection of malingering will certainly be punished by the boards or courts—the employee who is faking will fear the consequences. Fear goes a great way to keep people straight who otherwise might be intentional malingeringers. This fraud is the meanest of all and should be severely dealt with.

The Group of Diagnosticians

This group would include a well paid medical commissioner, skilled in industrial medicine and surgery and in the detection of malingering, and well paid chief medical examiners.

Employees may have their own opinions, but they cannot seem to learn that after certain disabilities working will do more for them than medicines or treatment in hastening a cure.

The difference between the patient visiting his own doctor and being examined by the commission's expert is that in the former case the patient seeks advice, while in the latter case the patient squeezes symptoms to fit the condition. The former doctor is perhaps biased. The expert is unbiased and, while giving the employee the benefit of the doubt, he is an administrator of justice to all, especially that great class of honest employees who say, "I don't want anything for myself. I want a good body and to get back on the job."

The expert should be acquainted with industrial conditions so that his judgment as to a finger injury would be fair to a tailor or watchmaker, while the same injury would be less disabling to a foreman or driver, and the return-to-work order should accordingly be influenced.

The expert should study the individual and know character. He should know when to agree with dishonest complaints and when not to agree.

He should have a fair knowledge of decisions of state boards and courts in various types of cases, as his questions and the answers thereto may prove of great value to the commission in legally interpreting a malingerer's statement.

Finally, he should have a thorough knowledge of pathology. This is essential to account for many of the symptoms alleged by a malingerer. It is of untold value in the hundreds of tests to check malingeringers. That is something of which

the malingerer knows nothing. This will stop the testimony of unscrupulous doctors concerning a wonderful pathological condition, invented in the hope that the lay members of the board will give the patient the benefits.

A Summary of Conclusions

In attempting to recognize the disease, investigate the causes, and treat the condition, there has been one point in view—that of returning the sick or injured employees who tend to malingering to work in the shortest time consistent with good recovery. This saves an economic loss to the employer and protects the honestly disabled employee who, by reason of his honesty, should profit in proportion as the malingerer should suffer. The American spirit requires justice for all.

Stress has been laid on well trained industrial surgeons. This is because, in my opinion, few mistakes could be more serious or do more real harms than to stigmatize an honest man as a malingerer. It is possible by proper methods to prove malingering. At the point of doubt the medical commissioner is essential, and his opinion should prevail on all medical questions. A number of malingeringers get surprisingly well before they will submit to be examined by the chief surgeon or medical commissioner.

The malingeringers cause the medical profession making impartial examinations to view any case with suspicion until proved innocent. If we can minimize the number of malingeringers, we shall have done much for the honest sufferer. We shall also save the toiler from moral degradation which follows misspent time and unearned income. The detection of malingering is a highly specialized branch of medicine, for by it society pays its just debts, fraudulent claims against innocent parties are prevented, and industry receives back the men as useful members instead of their being leeches on society.

THE RELATION OF H. C. L. TO DISEASE

A study of economic conditions in relation to disease and their responsibility for certain diseases has been made by Louis I. Harris, M.D., director of the Bureau of Preventable Diseases, Department of Health, City of New York, for the purpose of determining the nature of medical treatment necessary and to stimulate the development of social, economic, and legislative remedies. The economic, social, and domestic difficulties which may surround a patient should be understood by both the physician and the public health nurse, he says, in order that remedies or treatment which he may be able to secure may be prescribed, or means for procuring them be arranged for. In gathering the data, which has been compiled in an article "Some Medical Aspects of the High Cost of Living," Doctor Harris was assisted by trained workers.

INDUSTRIAL HEALTH HAZARDS

BY CHARLES A. LAUFFER, M.D., MEDICAL DIRECTOR, RELIEF DEPARTMENT, WESTINGHOUSE ELECTRIC AND MANUFACTURING COMPANY, EAST PITTSBURGH, PA.*

THE human dynamo generates a fixed quota of energy. If speeded up, it stands a determinable over-load with immunity; if given rest periods, kept in repair, and properly sustained, the human dynamo will last three score years and ten, probably longer. The over-loaded dynamo develops heat, in consequence of which wear and tear are greatly accelerated; if temperature readings show that the dynamo heats up too much, an early breakdown can be definitely predicted. The same applies to the human dynamo in which physical defects and psychic maladjustments, as well as speeding up, over-loading, and shortened rest periods, develop "heat," known as fatigue.

Modern industrial developments, collecting vast multitudes of men and women in industrial establishments, bring to the forefront the problem of health hazards. The vast exodus from rural to urban life during the past generation, forcing into indoor occupation individuals whose ancestors for generations lived out of doors, has further emphasized the problem of health hazards.

A study of these problems is vital to the employee; health, long life, and happiness are involved. It is fundamental to the employer; involving increased production, diminished labor turnover, contented ranks of healthy, happy, veteran employees,—all tending to bring increased profits.

The employee asks for himself and his sons: Is it a safe industry in which to seek employment? Is there any special liability of incurring a trade disease? Or of suffering early impairment in health? In short, what are the health hazards of this and that industry?

The industrial health hazards of the employees may be grouped as arising from: (1) poisons, dusts, fumes, gases; (2) heat, humidity, ventilation; (3) lighting; (4) crowding; (5) fire peril; (6) association with diseased employees.

ULTIMATE CAUSES OF DISEASE

Physical examination, by whatever agency, is a necessity. Proper placement requires the truth about defects. The truth, concealed, works the greatest hazard to the prospective employee.

The difficulty of separating purely industrial factors from those of outside agencies, or hereditary tendencies, makes it necessary to coordinate all health work, and perhaps makes desirable a health chart, certifying the health condition of all employees.

Compensation for disability, if just to all parties, implies a fair consideration of all causes of disease.

The Harvard chart gives a readily accessible grouping of the industrial poisons; a consideration of all of them would be out of place in this connection.

Lead, arsenic, and mercury cause definite toxic effects, when absorbed by workers in these metals. The most used poison is lead. Not every employee who handles a paint brush, however, gets lead colic. Some paints are innocent of lead; yet em-

ployees, who have never touched lead, will bring in diagnoses of "lead poisoning," merely because an attending physician knows they are painters. Lead storage in the tissues may ensue when lead is carelessly handled, yet lead poisoning is practically unknown in large plants handling hundreds of tons of lead every year. The extent of industrial lead poisoning, we know, is much less than some reports would have us believe. Employees who cannot be taught to wash their hands before eating, and who never clean their finger nails nor care for their teeth, are particularly liable to lead poisoning. Lead cannot be eaten with immunity, within or without the industries, but with individual cooperation, plus careful industrial supervision, the lead hazard can be mitigated. Precautions in handling lead reduce, almost remove, the health hazard from this source. Individuals who have once developed toxic lead symptoms should be given other employment, as the poison is cumulative and is never entirely eliminated; hence relapses readily occur, making permanent transfers to other lines of work necessary.

Industrial Dermatoses

Persons having a tendency to eczema or furunculosis may develop a skin rash from the solvents employed in removing varnish, shellac, and various insulation dope. Cutting oils, recovered by centrifuge methods, provoke skin infections.

*Read before the Eighth Annual Safety Congress, National Safety Council, Cleveland, Ohio, October 1-4, 1919.

Forced filtration through successive layers of filter paper removes minute metallic spicules, and filters out bacterial flora that affect the skin. Cutting compounds are often culture media for pathogenic bacteria, and may require sterilization by heat, chemical, and filtration methods. Minute burns from flying hot chips; abrasions by metallic spicules in dirty cotton waste used in rubbing hands and arms, rough scrub-brushes, or caustic soaps, may provoke such dermatitis.

Every industry has its own problem or succession of problems in this line. Persons manifesting such susceptibility should be transferred to other lines of work. Some individuals can work in chemicals for months without developing trade dermatoses, while others develop such trouble quickly. When 150 employees are subjected to the identical exposure, and only three develop industrial dermatoses, the factor of personal susceptibility is suggested. Attention to the toilet,—thorough, careful cleansing of the skin,—tends to reduce industrial dermatoses.

Dusts, Fumes, and Gases

Dusts and fumes are drawn out at their source, in the well equipped modern factory, so that the factory atmosphere is, or can be made, relatively clean. There are justifiable grounds for pride where a wholesome factory atmosphere is maintained. The competition between factories to make working conditions the best possible has not yet been over-worked, and can be promoted to the mutual advantage of both employee and employer. It is up to the initiative of employers, cooperating with architects, ventilating, heating, and lighting engineers, and employees' committees, to make working conditions safe from the health standpoint.

Pulmonary tuberculosis should be mentioned in its relation to dust and fumes. Dusts in themselves are not infectious. Dusty air is not salubrious but with the dust evil minimized, as in modern industries, there are few occupations that can be condemned as unfit for healthy men.

We are told that guinea pigs kept in cement mills develop no calcicosis, and employees seldom do. While the controversy over cement dust still rages, its dangers are less excessive than some have imagined.

The dust menace in other trades is, in comparison, relatively negligible. Coal miners develop more or less anthracosis; iron workers may develop siderosis. Marble cutters formerly developed calcicosis, which health hazard is now much reduced by suction devices for the removal of dust at its source. The inhalation of foreign particles, such as coal, iron, stone, textile fibers,

animal hairs and furs, grain dust, gives rise to pigmentation of the lungs. This pigmentation in itself is of no consequence and everybody has it to some extent.

Dusts are mostly filtered out in the nose; if the dusts reach the bronchial tubes, they are caught in the bronchial cellular cilia and coughed up, being expectorated with the bronchial secretions. It is contended that none of the dust reaches the alveoli. Particles that reach the peribronchial lymph nodes, and the mediastinal lymph nodes, penetrate through lymph channels from the bronchia.

Pigmentation Plus Infection

Pulmonary pigmentation and lymph node infiltration are not dangerous until tubercle bacilli have been implanted. Where has this or that victim of pulmonary tuberculosis acquired his disease? There is no definite period of incubation for pulmonary tuberculosis. So much time elapses between the exposure to the tuberculosis infection and the frank incidence of the disease that the real source of infection may have passed unobserved. The tuberculous area can be walled off for many years, lying dormant all that time, but finally a dissemination may occur from the old focus of infection. Some observers go as far as to say that the primary tuberculous invasion occurs before the fifteenth year, before tissue immunity is established, and that the tuberculous manifestations of later life are but recurrences of the earlier tuberculosis.

A survey of pulmonary tuberculosis in a textile industry in which dust inhalation was the alleged cause of the disease demonstrated that 85 per cent of the cases investigated showed a tuberculous near relative, or other immediate household source of infection. The remaining 15 per cent had a more remote source of tubercle bacilli infection, not revealed in this casual survey. The modern consensus of opinion has declared organic dust to be harmless; there is consequently no tuberculosis hazard from the textile industries. A study of pulmonary tuberculosis incidence on the basis of occupation, as afforded by the great sanatoriums at Cresson, Mount Alto, and Hamburg, Pennsylvania, conclusively demonstrates that no occupation is exempt. The great white plague can be fastened on no single industry, nor group of industries.

Recruits for Tuberculosis Army

The classes of employees that recruit the tuberculosis army are chiefly those who have relapses of old tuberculosis; those with tuberculous wives; those living in houses infected with tubercle ba-

elli; those who have in other ways been exposed to the insidious, slowly acting infection.

Association at work or anywhere else with persons having active pulmonary tuberculosis is a menace to health. Non-tuberculous employees should be spared the hazard incident to working near employees who are coughing and spitting in the active stages of pulmonary tuberculosis. Health service measures within the industries prevent their employment, and endeavor to isolate employees suffering from active pulmonary tuberculosis and other communicable diseases. As no such supervision is exerted over the home life, street cars, theaters, etc., it follows that the factory environment is relatively free from the peril of tuberculosis and other communicable diseases.

Tuberculous individuals often gravitate to industries where the jobs are light, and the work within their ability. In the quiescent stage of their disease, these men should be employed. Moreover, many employees work indoors who should work outdoors. The high incidence of pulmonary tuberculosis attributed to certain industries requires appreciative consideration as an industry is scarcely responsible for an injudicious choice of occupation on the part of an employee suffering from or predisposed to pulmonary tuberculosis.

Dangers of Indoor Life

Tuberculosis is a house disease; indoor life is largely responsible. It cannot be fairly classed as a trade disease. The purely industrial diseases are but a fraction of a per cent of the sum total of industrial morbidity; they are but a drop in the bucket. The preventable diseases non-industrial in source loom large in comparison. Teeth and tonsils, "coughs and colds" cause a hundred times as much sickness in the general industries as do the industrial poisons.

The segregation and isolation of persons with "colds" is considered good practice, as "colds" are "catching"; "coughs and colds," moreover, are communicated by crowding together in factories, and susceptibility to such infections is heightened by poor ventilation, drafts, overheating, neglect of humidity control. These problems of engineering successfully solved, make the factory atmosphere safe and minister to the health and comfort of all parties concerned.

The Hazard to Employers

These industrial health hazards affect employers as they relate to (1) decreased production; machines lie idle; sick employees are irregular, discouraged, and lack "pep"; (2) excessive labor

turnover, due to ill health, unfitness for jobs assigned, prevalence of epidemic and infectious disease; (3) increased accident compensation expenditures, due to sickness masquerading as injuries. Cases arise daily in which conditions are pathological, but trauma is alleged; or in which a minor trauma has provoked a prolonged period of disability, or an unusual degree of permanent impairment follows injuries, not in consequence of the gravity of the injury, but owing to intercurrent disease, or the previously impaired vitality of the traumatized individual.

The government employs only healthy men for the fighting line, whose ability to recover from wounds is 100 per cent plus. The industries necessarily employ many aged and feeble men, suffering from latent diseases and infirmities, having enfeebled powers of resistance and incurring delayed recoveries when injured. The industries are consequently entitled to sympathetic consideration in the vast economic problem evoked by injury plus sickness.

A term of disability may start as an industrial accident, the trauma being admitted, yet the period of disability is prolonged indefinitely by complicating sickness. Latent disease is activated by the trauma; or the disability is prolonged by sickness arising from other causes, or from pre-existing diseases unrelated to the trauma sustained. Fully "fifty-seven varieties" of sickness are presented as industrial accidents in entering compensation claims. Among these may be mentioned tuberculosis; syphilis—in various disguises; rheumatism,—teeth, tonsils, gonorrhea, each contributing their quota. These latent diseases, and others, are activated by trauma.

Remedial Measures Suggested

Since these health hazards face the industrial manager, what can be done about it? How can they be avoided? Measures to this end are:—

1. *Industrial Health Clinics.*—Group diagnoses; health service measures; repairing defects; reclaiming those disabled by diseases, as well as those crippled, and fitting them into selected positions in the industries; health education.
2. *Legalized releases for defects that cause abnormally long periods of accident disability.*—Hernia, varicocele, varicose veins, healed tuberculous foci in joints, lungs, etc., valvular heart defects, eye defects, amputations, etc., should be charted, and an employer should not be made financially responsible for defects and diseases arising from causes unrelated to the employment, nor for aggravations of the same.

3. *Obligatory Post Mortems.*—When the cause of death is in dispute, the report of the post mortem should terminate the controversy. So many deaths, occurring from pathological causes are reported as arising from accidental injuries received in the course of employment, that post mortems are essential, if justice is to be done all parties.
4. *Federal Health Charts.*—Transient employees lose a day in order to undergo the physical examination that precedes their employment. A Federal health chart, renewed annually, valid everywhere, would be invaluable for the transient as well as for the continuous worker who remains loyally by his employer year after year. The onus of the physical examination should be removed from the industries. Proper placement in industry requires the truth about physical defects. The truth concealed, works the greatest health hazard to the prospective employee.

An annual health inspection by the staff of a diagnostic clinic for every citizen between ages of eighteen and fifty-five could be achieved under Federal supervision. The surgeon general's office could establish in every community a Federal "Good Health" station, emphasizing diagnosis, and could recommend such remediable measures as the health maintenance of every citizen of draft age requires both for industrial service and for war. The early correction of defects is desirable; the early recognition of incipient diseases leads to successful treatment.

Annual re-examinations would constitute a splendid follow-up system to ascertain whether recommendations made as to teeth, tonsils, hernia, varicocele, diet, exercise, etc., had been followed out.

Nation-Wide Federal Health Service

Nation-wide Federal health service, devoting its energies to diagnosis, would not interfere with existing agencies for the treatment of medical and surgical cases, hence would not in any manner antagonize practitioners of medicine, existing sanatoriums and hospitals. A Federal educational propaganda for good health, however, by its recommendations could rapidly reduce the percentage of remediable defectives in the nation and so arouse public opinion as to enforce remediable measures in the incipient stages of defects and disabilities.

Federal health charts, with photographs, finger prints, and complete data of physical findings, would aid employment agents in rapidly placing men in the industries so that they would stay

placed. Health charts would not debar worthy men from the industries, but would facilitate in so placing them that their defects and morbid tendencies would militate least against them.

The proposed health charts could be the means of tabulating the availability of men for military service, hence would serve the exigencies of war preparedness, when men of draft age are again called out. They would likewise serve the industrial purposes of peace.

The day may be near, or remote, when a United States cabinet officer presides over a Department of Health; or when the Surgeon General of the Army is represented by a personnel as numerous and as widely distributed as that of the Postmaster General. Federal health charts, however, and a universal diagnostic clinic service which would make such charts possible are, however, devoutly to be desired; and, until obtained, physical examination must be conducted within the industries, as at present, in a fragmentary and incomplete manner. They should be extended if possible. If conducted with the frantic haste that too often has characterized these examinations in the past, the same indifferent valuation will adhere to this service as heretofore.

Other Health Hazards of Employees

Employees encounter health hazards apart from industrial service, that revert, affecting their industrial life. Such health hazards may be grouped as:

1. *Inherited Tendencies.*—Bad or indifferent physical and mental endowment.
2. *Family Problems.*—Unhappy home life menaces industrial safety and health.
3. *Financial Problems.*—Worry over bad investments, high cost of living, wife's or children's extravagances or other matters may induce more fatigue than the day's work.
4. *Social Life.*—The employee may belong to too many things, and, being too popular, lose too much sleep. An employee's occupation may have less to do with his health and his continued industrial efficiency than the way he spends his evenings.
5. *Housing Problcms.*—Individual houses are desirable to afford every family its own home in sewered towns with paved streets. Crowded tenements and boarding houses contribute to health impairment.
6. *Community Health.*—The acute infectious diseases encountered in the industries of any community are a reflection of the diseases then prevalent in that community. Measles, mumps, typhoid fever,

scarlet fever, influenza, grip, "colds," bronchitis, pneumonia, and smallpox are encountered. Isolated cases of these diseases, sometimes endemic, or epidemic, occurring in industrial plants are traceable to community sources of infection.

7. Neglect of Personal Hygiene.—

(a) *Neglected Teeth.*—The neglect of teeth among industrial workers is appalling. Putrescent stumps, dental abscesses, pyorrhea, and incomplete dentures are common. Money is spent more cheerfully for most everything else than for dental prophylaxis and dental repairs. The teeth constitute the first line of defense in conserving the digestion. Swallowing food swarming with myriads of bacteria from putrescent teeth causes indigestion. No man would buy a horse that has lost its teeth. "Life is digestion"; our strength and energy come from our food, yet some men are so unreasonable as to attribute their ill health and impaired strength to their work while neglecting their teeth, thus denying their bodies the rejuvenation that comes from wholesome food, thoroughly masticated, and thereby properly prepared for assimilation.

(b) *Diseased Tonsils.*—Tonsillar infections, both locally and by referred manifestations, cause much loss of time in the industries. The alleged injuries in which there are no visible nor palpable evidences of trauma, such as alleged sprained back (lumbago), alleged sprains of shoulder, elbow, wrist, ankle, as well as the several types of arthritis, rheumatism, and neuritis, have the tonsils as possible portals of entry for the infection.

(c) *The Venereal Peril.*—All three venereal diseases, in their infectious stages, should bar employees from industry. Stricture and other complications cause lost time years after the gonorrhreal infection has been forgotten. The bone injuries of old syphilites, with case reports; syphilitic leg ulcers, also masquerading as injuries; gummatous and sinuses, presenting long terms of disability, arising from slight injuries; and serious results in mild eye injuries, if recorded in detail would attest the excessive liability to injury and the poor recoveries registered by syphilitic patients in the industries. Wassermann tests, as a routine hospital measure, are in order.

(d) *Physical Defects.*—Hernia, eye

strain, etc., are known to exist, yet repair and corrective measures are postponed.

Constipation is woefully neglected. Neglect of home sanitation, ventilation, etc., the lack of a balanced diet, and deficient sleep are all common causes of disability.

Remote Causes of Deficiencies

Most men before thirty are second raters or third raters. Physical defects exist and morbid processes are implanted from early life, frequently before the industrial age. Physical examinations in the public schools are often farcical. Many remediable defects are overlooked, while those encountered are merely reported to parents who infrequently act upon such suggestions. Consequently, the industries receive multitudes of second raters, who develop into third raters. Had their defects been corrected early and had their mode of life been more hygienic they could give a better account of themselves.

An employee spends only eight or nine hours a day in industrial service. In his home, community, and social life during the other fifteen or sixteen hours of the day he likewise incurs health hazards. The superior lighting, heating, and ventilating systems installed in many modern factories make these industrial plants more hygienic from a public health standpoint than the homes, movie theaters, and churches, many of which are more crowded and worse ventilated. To be consistent, homes, boarding houses, hotels, theaters, and clubs in which employees spend more hours than in the factory should be scrutinized and inspected as industrial plants now are, in probing sources of health impairment and routes of infection from communicable diseases.

The industrial sick rate is augmented by a variety of physical defects most of which are remediable. Those that cannot be cured can be adequately relieved to enable employees to keep at work, if they so elect. A man must be reasonably healthy to be an efficient worker. A small maladjustment, a minor neglect, will sometimes lead to serious complications. An employee with a toothache whose attention is thus distracted will give more thought to his tooth than to his job. An ingrown toe nail is preventable; through neglect or improper treatment, it may cause lost time. Elementary hygiene and the proverbial "stitch in time," must be observed, if a man in industry, or out of it, is to maintain his health and efficiency.

Although there are industrial health hazards, and although the zeal in discovering and elimi-

nating them is commendable, the facts remain that purely industrial diseases are very rare in the general industries and that preventable, non-industrial ailments are the preponderating cause of sickness disability and health impairment.

Sickness and Accident Disability

The daily contact with industrial disability, both sickness and accident, brings one in touch with their intimate interrelation. Septic absorption from such foci as teeth, tonsils, prostate, accessory nasal sinuses, peribronchial lymph nodes, etc., causes much of the disability improperly labeled as injury. Patients like to be told that their occupation does not suit them, that their work disagrees with them; but they may resent it if told that their teeth need repair, that their tonsils should be removed, that correcting lenses should be worn for their failing vision, or that arch supports are required.

This leads to the question of industrial fatigue. If a man works hard enough and long enough he will naturally get tired. Industrial fatigue may not be excessive, but the fatigue from other sources combined with the industrial fatigue may prove detrimental to an employee. For a man to be fair with himself and with his job, he must ascertain to what extent his job is tiring him out, and to what extent his fatigue arises from such emotional causes, as domestic affairs, financial cares, worry, etc.; from septic absorption, as teeth, tonsils, prostate, etc.; from physical defects, as eye strain, impaired hearing, flat feet, hernia, etc.; from latent diseases, as incipient tuberculosis, etc.; from acute infections, as grip, nasal catarrh, bronchitis, etc.; from improper diet; from unhygienic home conditions; from loss of sleep; and from other potent factors that may enter into the equation in the accurate estimation of his total fatigue.

A worker who is constantly fatigued from any cause or any combination of causes will lose time now and then from sheer exhaustion. The fatigued worker is more susceptible to infectious diseases, from which he makes a retarded recovery; he becomes more stupid and, because less alert, he more readily meets with accidental injury, from which he recovers slowly since he has impaired vitality, and we have injury plus sickness to deal with.

The Industrial Clinic

There being this interrelation of sickness and accident disability, constituting the twilight zone of sickness and injury, it naturally reverts to the industrial clinic to find out the sources of fatigue, to evaluate the factors that contribute to the

fatigue total, and to facilitate the recovery of the individual in the manner indicated by the findings of the inquiry.

There arise specialties in industrial practice when an industrial diagnostic clinic is organized. Specialization is needed, employing diversified talent and training, such as required on a hospital staff. Beginnings of the industrial diagnostic clinic are observed at many places. The scope of specialties now covered are: (1) operative surgery, clean; (2) septic surgery. It is ill advised to allow the doctor who treats boils and infected wounds to care for fresh injuries, or re-dress clean cases. (3) physical diagnosis with special reference to heart and lungs; (4) x-ray service, developing into an ever larger field; (5) dental service; (6) pathologist for sputum, urine, blood, Wassermann examinations, tissue staining, vaccines, etc.; (7) oculist for injuries and diseases of the eye and optical service.

In addition to these special lines of medical and surgical service the works dispensary, as occasion demands, consults with orthopedic and general surgeons, internists, alienists, neurologists, dermatologists, oculists, ear, nose, and throat specialists, endeavoring to establish correct diagnoses, and cooperates in every legitimate way with the best available agencies for speedily restoring the disabled to health and to industry. Where the plant employs but few industrial physicians, group diagnoses, the collective findings of a diagnostic clinic, may be accessible elsewhere. The multiplication of such centers, within and without the industries, in the interest of health conservation, is much to be desired.

Community Health

The coordination of industrial and municipal health activities, as in Akron, O., offers a solution of the problem of controlling epidemic diseases. With the community health problems solved the industries will be spared the absenteeism from this cause, and the slackened production incident thereto. The works dispensary can become an out-station of the city department of health, with test tubes for throat cultures so that suspicious throats may be swabbed when the patients are sent home, and in order that no delay be encountered in getting reports on findings to attending physicians.

The control of industrial health hazards is entirely a matter of the initiative of the industrial management. Health engineering experts, consulting physicians, specializing in the reduction of health hazards, are being employed by the industries in conjunction with engineers in associated lines to reduce these hazards.

Educational effort from within the industries strives to stimulate the initiative of employees into foresightedness along health lines. To what extent the industries can enter into community activities without becoming paternalistic is a debated question which we will not discuss. Model house building enterprises, helping employees acquire their own homes, building and loan associations, banking, stores, and restaurants on the no-profit basis; clubs, social centers, playgrounds; hotels for employees; industrial and technical schools; apprentice courses with technical schooling; athletics, bands, and glee clubs are among the forms of community enterprise fostered by many of the larger industries which have the endorsement and approval of employees.

The new spirit abroad recognizes participation in industry as in the nature of a social service.

Constructive good-will—based on mutual confidence and real justice, alone can operate effectively to solve the problems to which industry gives rise. In the trinity of production, Capital, Labor, and the Community must unselfishly co-ordinate their common functions of serving one another.

There are health hazards within the industries that industrial initiative should control; within the communities that the coordination of industrial and community health service can control; and within the scope of the individual there are health hazards which require his personal initiative to combat successfully. With such coordinated efforts, the human dynamo will generate energy uninterruptedly, and the worker, secure in the enjoyment of a fair share of the rewards of toil, can live to a ripe and honored old age.

THE TREATMENT OF BURNS*

BY W. I. CLARK, JR., M.D., NORTON COMPANY, WORCESTER, MASS.

MOORHEAD,¹ writing of burns says: "Practically speaking, they should all be regarded and treated as infected wounds due to heat."

Colcord² in a most careful discussion of burns and their treatment says of a visit to a hospital where there were many burned cases: "Every burned surface was covered with pus, and the smell was disgusting. Many writers speak of the absorption of pus from suppurating burns as a frequent cause of death."

Septic Tendency of Burns

Why is it that burns tend to run a septic course? The heat which is sufficient to kill the cells of the skin layers in a third degree burn should certainly be strong enough to destroy microorganisms upon this skin, and it undoubtedly does. Thus a burn is an injury to one or more layers of the skin resulting in death of the exposed tissues, and is readily infected either direct from without or from neighboring skin.

Therefore if we can keep a burn sterile it should, after the separation of the slough, become a clean granulating wound and follow the same course as other wounds of this type.

While epithelium will grow on an infected surface its growth is slow and unsatisfactory as compared with its growth over a sterile surface.

It is exceedingly difficult to maintain sterility in a burn of any magnitude. Even with the greatest care any wound which is frequently

dressed becomes infected, and this is particularly likely to occur when a mass of dead and partially devitalized tissue is the type being treated.

In considering the treatment of a burn we have to consider two things, the treatment of the burned individual and the treatment of the local condition, the part burned.

The treatment first should be directly for the burned individual. The conditions to be combated are shock and nephritis. Secondary conditions such as fever and pulse-rise, with meningeal symptoms, vomiting, and diarrhea, and sometimes symptoms of gastric or duodenal ulcer, may appear as a result of thrombosis and toxic absorption from the local burned area. These must be met as they arise.

The order of treatment is as follows:

(1) Put the patient to bed in a warm room with hot water bags to feet.

(2) In removing the clothes, cut around burned areas, being careful not to tear the clothes from the skin and cause additional trauma and avenues for infection.

(3) Protect the burned areas thus exposed by covering with sterile towels or sheets.

(4) Give patient one-fourth grain morphin with one one-hundredth grain atropin by hypodermic. Repeat with caution if necessary.

Morphin is a stimulating narcotic and if used carefully can be employed to combat the shock without risk.

*Read before the Eighth Annual Safety Congress, National Safety Council, Cleveland, October 1-4, 1919.

1. Moorhead, John J.: Traumatic Surgery, 1917, p. 616.

2. Colcord, A. W.: International Jour. Surg., May, 1919.

(5) As soon as possible, start a Murphy drip in order to combat shock and supply fluids to the kidneys.

(6) When patient's condition begins to improve start treatment of the local burned area.

The local treatment of a burn is practically the same for first degree, second degree, and third degree burns. One or all types may occur in any case.

The first degree burn involves only the outer layer of the skin; there are no blebs following and no scarring results. The first, last, and only treatment needed in this type of burn is to powder freely with powdered stearate of zinc. When this type merges into second or third degree burns in the neighborhood the whole area would best be treated with a solution dressing. Before this is applied, however, a careful cleansing of the skin with a mild antiseptic is carried out. This must be done thoroughly but gently, especially around the burned areas. For the skin three or four inches from the burn benzene applied with cotton mops and followed by 3½ per cent tincture of iodin is probably the most satisfactory method of sterilization. As we approach the burn, ether should be substituted as it is less irritating. It is applied with cotton mops. The doctor should wear sterile gloves, use sterile instruments, and if he opens blebs should first sterilize the area with 3½ per cent tincture of iodin. Moorhead recommends puncturing the bleb aseptically at the junction between the sound and unsound skin.

After the surrounding skin has been prepared and the blebs attended to, the burned area should be covered with a suitable sterile dressing. There are three types of dressing now in use.

(1) Wet solutions of which the most favored are 1 per cent solution of picric acid and saturated solution of bicarbonate of soda.

(2) Ointments, of which the most used are boric acid and soda bicarbonate, 3 per cent. A number of special burn ointments have been developed, two of which have been so thoroughly tried out that their formulae will be given.

FIRST OINTMENT.—Used by Dr. A. W. Colecord in the treatment of 8,000 burns.

R

Carbolie Acid	'
Thymol	
Menthol	
Camphor of each gr. 5	
Ichthyol	
Balsam of Peru of each gr. 10	
Zinc Oxid	
Starch of each 1½ drachms	
Petrolatum to make one ounce. Mix well.	

Doctor Colecord uses this ointment in one-

sixth strength from the start, applied daily with aseptic precautions.

SECOND OINTMENT.—Used at La Panne,³ Belgium, during the war.

R	Vaselin	20
	Lanolin	20
	Antipyrin	60
	Boric Acid	60
	Salol	20
	Iodol or Iodoform.....	20
	Phenol	20
	Bichlorid of Mercury.....	02

This ointment gave extremely good results and was used with aseptic caution.

(3) *Third type of primary dressing.*—The third type of primary dressing is warm wax. This method started with the proprietary substance ambrine, but it has been found that the action is only mechanical so that there are a number of mixtures of paraffin and resin now on the market which are quite satisfactory. One used at the American Steel and Wire Company, and Norton Company at Worcester consists of:

Paraffin	70
White Wax	20
Resin	10

All of the combinations are dispensed in solid form and must be melted before using.

Technic of Wax Dressing

The method of applying the wax is first to dry the skin thoroughly, using an electric blower such as is used in barber shops for drying the hair. After the area to be treated is thoroughly dried, the wax is either sprayed or painted on. Spraying is wholly painless, painting nearly so. The wax must be just liquid before being applied and can best be melted down in a double boiler. When the wax is painted on, sterile cotton swabs on applicators are the best instruments to use. The warm liquid wax should be dabbed on not "painted." The wax hardens almost at once, forming a smooth coating extending over the sound skin for a short distance on all sides of the burned area. Upon this thin hardening, wax layer sterile sheet wadding which has been dipped in the wax is laid and over this another layer of sheet wadding. The whole dressing is held in place by a bandage. The advantage of using wax is the immediate covering of the burned area with a smooth sterile protecting surface with splinting of the injured part.

The wax is removed daily coming off *en bloc* with the sheet wadding. The secretions underlying it are washed off with normal saline, the area

3. Sand, Dr. René, Belgium: Personal communication.

dried with hot air, and a fresh wax dressing applied.

It seems to make little difference which method is used if the work is done carefully and absolute aseptic technic maintained throughout. Personally, the author prefers a sterile saturated solution of soda bicarbonate for the first few dressings. It is easy to apply, gives considerable relief to the patient, and requires less technic and handling of the injured area than the ointment or wax. It should be applied by saturating a piece of old sterile sheeting in the solution and wrapping this loosely about the burned area. The moisture is maintained by surrounding the wet linen with oiled silk. The dressing can be moistened from time to time by lifting a corner of the silk and carefully adding the solution.

If there is little sloughing the ointment or wax treatment can be instituted; but if much sloughing is present a moist dressing will be needed. The disadvantage of continuing the soda is that if any infection is present it is liable to flourish in the alkaline medium unless the medium is distinctly antiseptic. For this reason it is well to stop the soda dressing after twenty-four hours and use alum acetate solution.

R

Alum	pts. 5
Lead Acetate	pts. 25
Water	pts. 500
Dissolve separately and mix.	
Do not filter.	
Shake before using.	

This solution is mild, non-irritating, and antiseptic. It has a white precipitate which seems to have a very soothing effect upon the skin. The solution has been used largely at the Worcester City Hospital and elsewhere for burns.

After the slough has separated and granulations begun, the burn may be considered a granulating wound.

To Hasten the Healing

Three things must now be considered, encouragement of epithelization, care of the granulations, and prevention of a deforming scar.

Epithelium forms from the germinal layer of the skin and its down pocketings, and it is from this layer that fresh epithelium is formed. Three things seem to assist epithelization greatly: (1) a sterile granulation tissue to grow over, (2) a smooth surface to grow under, and (3) pressure.

The difficulty of preserving sterile granulation tissue has been mentioned. If it can be preserved, wax provides probably the best type of surface to grow under. Its chief advantage is the ease with which it can be removed without injury

to the newly formed epithelial cells. At the Ambreine Hospital in Paris a thin layer of sterile zinc oxid ointment is applied along the epithelial edge further to protect the cells especially when the hot wax is applied. The cleansing of the wound after the removal of the wax is easy as compared with the cleansing of a wound covered with ointment. However, when there is any tendency to infection of the granulating surface, the ointment is probably somewhat preferable because of its antiseptic properties. The importance of pressure in the healing of granulating wounds was first noted by the author when examining a series of burns in the Worcester City Hospital. Burns of the back were in all cases progressing better than burns of the chest or extremity, and it was concluded that pressure was an accelerating factor. It seems to make little difference as to the type of covering which is employed, provided it is smooth. Thus sterile adhesive plaster has been used by many, and the author has obtained good results with gutta percha tissue, if there are no wrinkles or air spaces.

Granulation tissue, once infected, is almost impossible to sterilize, as those who worked in France know only too well; therefore the basic principle in the treatment of burns, as in all surgery, is to keep asepsis of the wound if possible and, if in spite of all care it becomes septic, endeavor in every way to render it again aseptic.

In burns involving a large area the burned area always becomes infected. This has been strikingly brought out by Fauntleroy and Hoaglund⁴ in their recent paper. In cases of this type it is obviously impossible to expect to obtain sterility. The method used in treating the very extensive and difficult burns employed by these authors, and also favored by Moorhead, is the open air treatment without any dressing at all. Massive crusts form over the burned areas and beneath these pus forms plentifully. Cases seem to do a little better if the crusts are not removed, but gently lifted when absolutely necessary to give drainage.

The crust forms a dressing very similar to parafin. Fauntleroy and Hoaglund, in discussing the treatment of these crusts say, "There seemed to be two separate, distinct periods, at which time two distinct results occurred simultaneously in all cases: the first period in which removal was continuously followed by the same heaping up process; the second period in which following a week's period of non-interference, removal at this juncture of the crust with the application of a thin layer of boric ointment on lint was followed

4. Fauntleroy, A. M., and Hoaglund, A. W.: Ann. Surg., June, 1919.

by a quick bridging over of the raw surface with new skin and complete healing with no scar formation in a few days' time."

Summary

While it should be possible to maintain sterility in burns, this is difficult and, when large areas are involved, almost impossible.

In treatment, the individual should be treated first, the burn second.

The treatment of the burned area may be divided into the primary treatment, which consists of cleansing and the application of a moist dressing, and the secondary or more permanent treatment, when open air, special ointments, solutions, or wax may be indicated.

Experience tends to show that absolute standardization of treatment is impossible in the secondary treatment as burns react in different ways; it would be advisable, however, to restrict the drugs and ointments to a minimum number, and to study each one carefully in order that a certain type of standardization may be obtained.

Emphasis should always be laid upon strict aseptic technic without which good results cannot be obtained.

MEDICAL BENEFITS UNDER WORKMEN'S COMPENSATION

Some of the difficulties in the administration of medical benefits under the Workmen's Compensation Laws have been due to basic defects which need to be remedied by further legislation. One of the most far-reaching in effect has been in placing time and money limitations upon such service instead of emphasizing the repair as far as possible of the injury and restoration of function. The relation of the hospital and workmen's compensation has been the subject of serious study by the hospital people, and we quote in full their recommendations to the American Hospital Association which embody the result of their investigations.

"The 1918 legislative committee's report urged hospital workers and associations to assume something more than a policy of indifference toward the subject of hospital benefits under Federal and state workmen's compensation laws. It was urged in that report that the common legislative and administrative limitations on compensation for hospital service result in injustice to both injured workmen and to hospitals. The principles expressed in that report are again commended to the attention of this Association.

"The principle of 'hospital cost for service rendered,' which has had the general approval of this Association, is an absolute essential in workmen's compensation laws for the injured workman and for the hospital which cares for him. If such laws limit rates of payment, as well as the number of days of hospital treatment, the result is loss of opportunity for the complete restoration of the workman seriously injured in industry. It also often places the hospital in the position of a choice between doing 'charity work' for the state and the private insurance company, or of discharging the patient too soon. These are what Dr. Royal Meeker, United States Com-

missioner of Labor, calls 'leaks in the workmen's compensation.' His address on this subject, at the annual meeting of the American Association for Labor Legislation in 1918, should be examined by hospital workers and associations.

"The following facts should stimulate the organized hospitals toward securing legislation for necessary changes in workmen's compensation laws:

"(1) The principle of 'hospital cost for service rendered' does not seem to have been included in other state or Federal workmen's compensation laws.

"(2) Provision for adequate hospital treatment for injured workers is far more important than allowance of money benefits; yet four states make no provision for such services.

"(3) Twelve states limit the cost to one hundred dollars or less; sixteen limit the period to thirty days or less.

"(4) Only four states permit of adequate medical and surgical treatment by placing no limits in their laws upon the time or cost of such service.

"(5) Attempts are now being made to include occupational diseases within the provisions of workmen's compensation laws."

COMMENDS AMERICAN FACTORY HYGIENE TO BELGIAN GOVERNMENT

Dr. René Sand and seven associates who were chosen on a commission sent from Belgium to the United States to study and report on the methods and principles employed in factory management in this country take note of the movement in several cities and states to cause medical examinations to be made of all boys and girls entering the trades or professions as a means of preventing impairment of physical functions be a wrong choice of occupation.

The report of the commission is of special interest to American physicians by reason of Dr. Sand's observations on American medical and social problems in industry.

Harry T. Collins, trade commissioner for the United States stationed at Brussels, Belgium, submits a statement of the views presented by the Belgian commission, which is published in *Commerce Reports*, July 3, 1919. His outline of the report is reprinted in full below:

In April, 1918, the Belgian Department of National Reconstruction sent to the United States a commission instructed to investigate and report on factory management and the organization of labor from the scientific, social, and industrial points of view.

This commission, which remained in the United States from April to July, 1918, was composed of eight members, each of whom devoted his attention to some particular phase of the investigation. The following were members of the commission:

M. O. Stels, professor at the University of Ghent, president of the commission.

M. H. Mavaut, director of the National Belgian Labor Bureau at London. (*Office National Belge du Travail*.)

M. A. Van Hecke, professor at the University of Louvain.

Dr. René Sand, professor at the University of Brussels.

Lieut. Henri de Man, general secretary of the Workmen's Educational Union. (*La Centrale d'Education Ouvrière de Belgique*.)

M. F. Vandersypen, engineer of the Katanga Railroad Co. (*La Compagnie des Chemins de fer du Katanga*.)

M. Ph. Stels, employment manager for the Belgian State Railway. (*Ouvrier-brigadier aux Ateliers des chemins de fer de l'Etat Belge*.)

M. P. Dejace, formerly adjutant of the Ninth Regiment, acting as secretary to the commission.

M. Stels gave particular attention to technical and scientific questions; M. Mavaut to legislation and administration; Dr. Sand to social hygiene and industrial fatigue; M. F. Vandersypen and M. Stels studied the details of organization in certain factory types; Lieut. Henri de Man and M. A. Van Helle, representing labor unions, gave particular attention to social problems in American industry.

General Conclusions of Commission

The report of the commission will later be published by the Department of Industry and Labor. At the last meeting of the committee, February 24, 1919, the following general conclusions, which form the gist of the report, were unanimously adopted. These conclusions are of interest to American industry as a foreign analysis and description of its activity and more particularly because the commission recommends in some of its conclusions changes to be made following American methods and models.

(1) The system known in Europe as "Taylorism" and in America as "Scientific management" has not, as we generally believe, been in universal practice throughout the United States. The spirit of the system and the principles of scientific organization have, however, been successfully applied in a large number of factories and plants of various kinds. An art and a science of organization based upon observation and experience, are in the process of constant elaboration and are permeating all realms of American life, including the Army, public philanthropy, education, hygiene, and commerce, as well as industry.

(2) The members of the commission believe that the public authorities ought to encourage the diffusion of the principles of scientific management. To this end they should attempt to interest the employers and engineers, on the one hand, and employees on the other, in its study and application.

A special bureau attached to the Ministry of Labor or the Department of Economic Affairs would be useful for undertaking the publication of documents relative to this question. It should contribute by all possible means to enlighten public opinion regarding scientific management. It is desirable, on the other hand, that important state departments participate in the movement and thus assure the development of methods as recommended. Special bureaus for this purpose ought to be created in the Railroad Administration, Department of Agriculture, and the Administration of Public Works. Such special bureaus should have direct connection with the general secretary of each of these departments.

(3) The introduction of an entirely new spirit in public education is necessary. Education ought, above all else, prepare the younger generation for activity in the modern world. The formation of character, a knowledge of public hygiene, and of economic and social problems, is of prime importance. The study of labor questions, of social hygiene, of scientific organization, of the rights of unions, of the psychology of labor, is indispensable to engineers, doctors, and lawyers. The principles and practice of scientific management ought to be taught to the future employees.

Cooperation of Employers and Employed

The same idea ought to prevail in the reorganization of professional instruction. In America and England, especially since the war, people have realized the importance of raising the intellectual level of the workers and increasing their technical knowledge.

(4) The members of the commission are able to state that the attitude of American industrial managers in regard to labor problems is very favorable to social progress. The conviction is becoming more and more universal that in order to increase production, it is necessary to place the worker in the best sanitary environment, to promote his general welfare, to encourage pleasant relations between employees and employers, and gradually to introduce the personnel into the problems of management, such as the fixing of conditions of labor and salaries, collective bargaining, and methods of dealing with laborers.

(5) Experience has in general demonstrated to the American industrial managers the advantage of a short working day and the value of the Saturday afternoon holiday. Due in large part to the intervention of the Government in war industries, the eight-hour day is tending to become quite universal in the United States.

Experience has shown the excellent economic and social results of the establishment in the factories of special departments, such as departments for the prevention of accidents, medical service (factory hygiene, periodical examination of workers, care of the sick and injured); employment department (charged with employing workers, and with placing and adapting them professionally). Other conveniences for workers include: Cafeterias, canteens, dressing rooms, drinking fountains, lavatories, shower baths, rest rooms, play grounds, libraries, clubs, workingmen's homes and gardens.

Lighting, ventilation, factory sanitation, and medical prophylaxis appear also to be important factors.

The problem of fatigue and that of the best method of fixing wages appears to the committee to be still unsolved.

(6) It is the general opinion in the United States that there should be equal wages for equal work, without distinction of sex. The employment of the mother of the family as a factory worker is not regarded as conducive to the welfare of the children.

It is the consensus of opinion in America that sixteen should be the minimum working age. A medical certificate of health, medical examination at stated periods, and professional instruction up to at least eighteen, are considered as eminently desirable for the younger workers.

(7) The introduction of a research bureau and a department of instruction, both general and technical, especially for the purpose of the professional adaptation of the workers, is spreading rapidly throughout the American industrial and commercial enterprises. In certain cases, the industrial managers unite for this purpose.

(8) Cooperation between industrial managers has been productive of good results in a number of fields, such as: Organization bureaus, common buying and selling organizations, apportionment of production, advertising, installation of common motor force for production, etc.

(9) Especially because of the tremendous importance of its domestic commerce, American industry has been able to increase national production by the specialization and standardization of tools and products, as well as by the development of mechanical means of labor.

(10) The creation of the National War Labor Board, consisting of representatives of workingmen's and employers' organizations, has been productive of excellent results, from the point of view of production, as well as in the prevention and solution of industrial conflicts.

(11) The members of the commission report that the high salaries common in America, corresponding to the high cost of living there, are accompanied by a much better standard of living than was common in Europe before the war.

THE NATION'S HEALTH

Public Health and Public Welfare, Administrative Medicine, Organized Health Service

THE FRAMINGHAM TUBERCULOSIS DEMONSTRATION

INVESTIGATIONS in regard to the etiology of tuberculosis which have been carried on during the past thirty-five years have revealed the main factors in the problem, and indicated several possible methods of control. We know that the germ of the disease is derived in a large majority of cases from the mouths of affected human beings, and in a small minority of cases from the milk of affected cows; the control of the careless consumptive and the pasteurization of milk suggest themselves as obvious sanitary measures. We know that local injury to the lung tissue, such as results from exposure to metallic or mineral dusts, and lowering of general vital resistance from underfeeding, deficient ventilation, alcoholism, and the like may constitute important factors in converting latent infection into active disease; the elimination of the dust hazard and the building up of the health of the people by hygienic and economic measures form a second possible line of defense. Finally, we know that the early active case of tuberculosis may generally be arrested, and the arrested case may generally be kept in that condition, by the strict observance of definite rules of personal hygiene such as are exemplified in the practice of the sanatorium; the prompt detection of early cases followed by sanatorium treatment or supervised home care constitutes a third possible method of control.

While we have, therefore, three different lines of attack upon the problem of tuberculosis, we unfortunately lack the exact knowledge of the exact quantitative importance of the various factors involved which would make it possible to determine the best weight to place, respectively, upon the control of sources of infection, the upbuilding of the vital resistance of the population as a whole, and the detection and care of early cases of the disease. In the absence of such

knowledge we have taken the line of least resistance. The control of all possible sources of infection and the creation of vital resistance throughout the whole population seemed tasks too vast to be seriously attempted. We have, therefore, controlled the grossest and most extreme examples of the careless consumptive, and have made a few half-hearted attempts at improving the environmental conditions in the tenement and the factory. The main stress, however, has for twenty years been laid on the detection of the early case of tuberculosis and the provision for it of sanatorium treatment or home nursing care.

The development of the anti-tuberculosis campaign along these lines has been accompanied by a marked decrease in the death rate from tuberculosis (from 201 per 100,000 for the Registration Area in 1904 to 142 in 1916). Grave doubt has existed, however, in the minds of many as to the existence of a causal connection between the two phenomena. It has been plausibly suggested that the reduction in the tuberculosis death rate which has taken place was due less to the anti-tuberculosis campaign than to a general improvement in vital resistance resulting from improvements in the standard of living, or perhaps to other still more obscure factors in the biology of the tubercle bacillus or its human host. Competent experts on tuberculosis have not hesitated to express a profound skepticism as to the question whether the anti-tuberculosis campaign as at present organized is actually yielding, or is capable of yielding, definite and tangible results.

In order, if possible, to solve this important question the Metropolitan Life Insurance Company three years ago made a gift of \$100,000 to the National Tuberculosis Association. A small, typical community was to be selected in which the most complete anti-tuberculosis campaign indicated by our present knowledge could be carried out as a demonstration experiment which should

indicate with some definiteness whether such a campaign could be expected to yield results or not. Framingham, Mass., was the town finally chosen for the demonstration, and the work was placed in the capable hands of Dr. D. B. Armstrong.

The time originally allotted for the experiment and the funds originally provided will both expire early in 1920. The National Tuberculosis Association, therefore, requested Surgeon General Blue to appoint a special Committee on Appraisal to report upon the work so far accomplished, and to make recommendations in regard to its possible continuance. The committee was appointed with Dr. A. J. McLaughlin as chairman, and on August 14 made its report, from which extensive extracts are reproduced on page 616 of this issue.

The conclusions of the Committee in regard to the work which has been accomplished by the Demonstration were highly favorable. It was felt that Doctor Armstrong and his associates have been successful in obtaining a fairly complete knowledge and a reasonably adequate control of the tuberculosis, both active and arrested, which is present in the community of 17,000 persons under their charge. The medical consultation service organized by Dr. P. C. Bartlett is given special praise as an invaluable contribution to the technic of public health organization, a service capable of application in many other fields besides that of tuberculosis. An account of the Consultation Service in Tuberculosis Work written by Dr. Donald B. Armstrong appears on page 633 of this issue.

During the progress of the demonstration the death rate from tuberculosis in Framingham has fallen from 93 per 100,000 in 1917, to 79 in 1918, and to 76 for the first five months of 1919. The Committee points out, however, that the period of three years is altogether too short to permit conclusions which shall be of substantial value; and shows by statistical computation that a continuation of the experiment for a period of five more years will probably be necessary in order to yield conclusive results. Such an extension of the demonstration should, however, make possible a clear answer to the question whether our present anti-tuberculosis program as exemplified at Framingham is or is not sound. If the answer is in the affirmative, we can proceed with confidence to modify the machinery devised at Framingham for more economical routine application on a larger scale. If the answer is in the negative, we must attack with renewed energy the theoretical problems underlying the etiology of tuberculosis in order to devise methods which shall be more effective.

It is gratifying to learn that the Executive

Committee of the National Tuberculosis Association has accepted the main recommendations of the Appraisal Committee and that the Metropolitan Life Insurance Co. has agreed to furnish the funds necessary for a continuance of the work. The completion of this most important community experiment in public health administration is therefore assured; and the vital statistics of Framingham will be watched by all public health workers with the keenest interest for the next five years.

EDITOR.

TAKING THEIR OWN MEDICINE

Not many bodies of physicians have measured themselves by the yardstick of accepted physical standards, but that is what took place at the International Conference of Women Physicians when Dr. Augusta Rucker, director of the health division, subjected the delegates of the conference to the Y. W. C. A. physical tests.

The first step in attaining the maximum of health is an examination which begins with the eyes and works down to the feet, taking into account posture, degree of strength, diet, constrictive clothing, and any other factors which influence health. "The human race might well adopt some of the customs of the stone age," says Doctor Rucker, "so detrimental are many of our habits to life." Compulsory physical examination at regular intervals is advocated. The same tests are recommended for children as for adults, the children to be examined yearly. Reasonable precautions may be exercised by adults if physical examination is made once every two or three years.

THE NEW TUBERCULOSIS SURVEY

The results of a survey carried on by the National Tuberculosis Association announced at the Russell Sage Foundation during the session of the Executive Committee in September indicated that the annual death toll of tuberculosis in the United States reaches the total of 150,000. This means more than 1,000,000 active and perhaps 2,000,000 unsuspected cases, according to the ratios developed from the Framingham experiments.

Among the noted experts at the conference were Dr. Victor C. Vaughan, president of the National Association; Dr. E. R. Baldwin of Saranac Lake, N. Y.; Dr. George T. Palmer, Springfield, Ill.; Dr. George M. Kober, Washington, D. C.; Dr. Hoyt E. Dearholt, Milwaukee, Wis.; Dr. Chas. White, Pittsburgh, Pa.; Dr. William H. Baldwin, of Washington, D. C.; and Dr. Charles J. Hatfield, managing director of the National Association.

As a result of the conference a fund of \$6,500,000 is asked to conduct an intensive educational campaign to impress upon all the people that tuberculosis is a preventable disease and to teach them the methods of protection against it. Plans are presented for the treatment of all afflicted persons and institutions are to be established for their care. Special activities will have as their object the detection of unsuspected cases of tuberculosis and the use of such methods as will arrest its development.

Electrotherapeutists Meet

The American Association of Electrotherapeutics and Radiology held its twenty-ninth annual session in Philadelphia, September 16 to 19, with an attendance of about five hundred physicians from this country and Canada.

NERVOUS AND MENTAL DISEASE AS A PROBLEM IN PUBLIC HEALTH

BY FRANKWOOD E. WILLIAMS, M.D., ASSOCIATE MEDICAL DIRECTOR, THE NATIONAL COMMITTEE FOR MENTAL HYGIENE, NEW YORK CITY

THE former division of health problems into major, those diseases which are communicable or infectious, and minor, all other diseases or conditions that affect health, is no longer tenable. Industrial hygiene and school hygiene, for example, have been found to be of much public importance; but in neither of them is infection the most important element. Tuberculosis and the venereal diseases remain health problems of the first importance, but their importance is determined, not by the nature of the diseases themselves, but by another consideration and a consideration that brings a new alignment in determining the relative importance of health problems.

Social Aspects of Nervousness

More important than the saving of any one life or any group of lives must be the saving of the structure by which all life is maintained. Hence it follows that, apart from all other considerations, that condition is of the greatest importance to public health the existence of which does the greatest damage to the social fabric. On this basis certain communicable diseases, as, for example, the venereal diseases, retain a place of the greatest importance, and communicable diseases as such will probably always retain the greatest potential importance. At the same time there are immediately thrown into relief certain non-contagious, non-infectious conditions that are found to have an actual and immediate importance not previously fully recognized. Among the group thus thrown into relief are the nervous and mental diseases.

Again, it is not the diseases in themselves that are of importance, but the destructive, corroding effect that these diseases have upon social life, frequently eating at the heart of family life, in

Herein lies the importance of nervous and mental diseases as a public health problem:

Not alone in numbers slain, though the number is large; not alone in the number of lives crippled, though the number is larger; and not in the burden of the expense entailed, though it is enough to give any community pause; but in the damage done to social structure by the struggle at adjustment and compromise of individuals ordained to failure. Infections may be eradicated and nervous and mental diseases may be reduced by intelligent, persistent health effort. These are problems for both physician and social service worker.

information in regard to their nature probably calls for a new assignment, but that does not concern us here. What does concern us is their social aspect. The study of the social effects of nervous and mental disease is comparatively recent, but it has been carried on over a sufficient length of time and with a sufficiently large number of cases and by a sufficiently large group of trained workers to amass a large body of data that warrant careful consideration. Medicine is not generally familiar with these data.

Statistics on Industrial Cases

Numbers alone cannot determine the importance of a problem of health. Coryza probably affects more individuals in a year than any other single condition, but coryza is not a major health problem, even granted that it may be of more importance than is generally conceived. Hookworm affects comparatively few, but so destructive is it in sapping the energies of a community that it must be reckoned as important in spite of the comparatively small number of its victims. The very large number of individuals affected annually by mental disease in the United States does not alone place its relative importance in the scale of public health problems, but before taking up more important considerations it may be well to review briefly certain figures.

The number of individuals cared for in hos-

pitals for mental disease has increased from 40,942 in 1880 to 239,820 in 1918—from 81.6 per 100,000 of general population in 1880 to 229.6 in 1918¹, as shown in the following table:

Year	Number	Per 100,000 of general population
1880	40,942	81.6
1890	71,028	118.2
1901	150,151	183.6
1910	187,791	204.2
1917	232,873	226.5
1918	239,820	229.6

The percentage of increase from 1910 to 1918 of those in hospitals in certain states as compared with the percentage of increase of the general population in those states during that period is as follows:

State	Insane in institutions	General population
Arkansas	45.1	13.0
Florida	48.8	23.2
Illinois	36.4	11.3
Indiana	26.0	5.3
Kentucky	26.6	4.9
Minnesota	30.8	12.2
Missouri	24.9	4.4
Montana	73.9	27.5
North Dakota	87.1	34.9
Texas	42.8	17.0
Utah	70.5	20.2

It should be borne in mind, of course, that these figures do not necessarily represent an actual increase in the amount of mental disease. What the actual increase has been, if any, it is impossible to determine. The apparent increase can on the whole be accounted for by the increased facilities for care in the way of hospitals that have been built and the gradual raising of the standard of care in the public hospitals so as to make them more acceptable to a larger number in the community. However, the figures are interesting as they stand. It should be borne in mind also that they are far from complete and do not show the amount of mental disease in any given state, since they show only the number of patients cared for in hospitals in the state, and can serve only as an index to the amount of mental disease. Not a state in the Union has provided adequate facilities for the treatment of nervous and mental patients. Everywhere there are over-crowding and delay because of lack of hospital beds. New York and Massachusetts have well regulated state hospital systems, but the state of New York has not built a new hospital in twenty years in spite of an average annual increase of 933 patients per year since 1910, and as a result the hospitals are badly over-crowded. Massachusetts has kept more abreast with her hospital building, but her facilities are inadequate. In other states, in which less attention has been given to the problem, conditions frequently beggar description. Pennsylvania still imprisons many of her patients in county asylums. These things are brought home to us with special keenness at this time, when it becomes necessary to find hospitals in which to

treat the returned soldier suffering from mental disease. The number of patients received annually by the hospitals for mental disease has increased each year since statistics have been kept. The total admissions to state hospitals for 1910 were 45,794; for 1917, 62,898. In Massachusetts and New York, two of the states in which a separate record is made of those who enter the hospitals for the first time, the number of patients newly admitted during the fiscal year ending in 1917 are as follows: Massachusetts, 4,085; New York, 6,877; a total of 10,962.

The significance of these figures is more readily grasped if they are stated in a somewhat different way. The figures for 1918 and 1919 are not yet available, but it may safely be assumed that they are not less than for 1917—as in previous years, they will no doubt show an increase. There are, then, in the state of New York more than 6,800 persons, and in the two states approximately 11,000 persons, none of whom has ever been inside a hospital for mental disease except, possibly, as a visitor, who at the present time are attending to their business, going about their daily duties, planning their recreations; but who, before this time next year, will have been committed as insane to one of the state hospitals.

Dr. Horatio M. Pollock, statistician of the New York State Hospital Commission, states effectively another phase of the same problem. Doctor Pollock points out that of the 35,213 patients resident in the New York state hospitals July 1, 1917, 18,940, or 53.81 per cent, where patients with *dementia praecox*. A census a year later showed that the number of *dementia praecox* patients had increased to 19,544. "If some unknown physical disease should strike down and kill 1,000 young people in this city (Brooklyn) during the current year," says Doctor Pollock, "do you think the medical profession, the newspapers, and the public generally would view the matter with complacency? Yet *dementia praecox* will come into this city as a masked enemy and steal away the minds of 1,000 young men and young women and condemn them to a living death during this year, 1918, and scarcely any public mention of the matter will be made."²

The cost of maintenance of patients in state hospitals during 1917 was \$43,926,888.88. In Massachusetts, New York, and Ohio, the cost of maintenance was as follows:

Massachusetts	\$ 4,438,101.33
New York	7,872,857.93
Ohio	1,954,811.51
Total	\$14,266,070.77

¹ Pollock, Horatio M., and Furbush, Edith: Annual Census of the Insane, Feeble-Minded, Epileptics, and Inebriates in Institutions in the United States, January 1, 1918, Mental Hygiene, 1919, III, 78-107.

² Pollock, Horatio M.: Dementia Praecox as a Social Problem, The State Hospital Quarterly, August, 1919.

These figures do not include expenditures for extraordinary repairs, new construction, or permanent improvements.

In addition to those above mentioned, more than one million dollars annually for the maintenance of patients in hospitals for mental disease is expended by Indiana, Michigan, Minnesota, Missouri, and New Jersey; Ohio expends approximately \$2,000,000, California and Pennsylvania more than \$2,000,000 each, and Illinois more than \$3,000,000.

In a recent study of 1,544 patients suffering from syphilitic mental disease in the New York state hospitals the statistician of the New York State Hospital Commission estimated that the annual loss to the state of this group alone is \$5,398,644.99, as follows:

Cost of maintenance of 1,544 patients in institutions.....	\$ 471,918.72
Loss of earnings of males.....	4,652,912.35
Loss of earnings of females.....	273,783.92
	\$5,398,644.99

The figures thus far given represent only the insane in hospitals. It should be remembered, however, that neither numerically nor socially are the insane the most important group of those suffering from the various nervous and mental diseases. It is probably fair to say that they are the least important. The figures given have not included either those who are feeble-minded or those with neuroses. While accurate figures of the number in these two groups do not exist, unquestionably each group exceeds the number in the insane group.

As Col. Pearce Bailey, formerly chief of the Division of Neurology and Psychiatry, office of the Surgeon General, Washington, has pointed out, "the neuropsychiatric examination in the army disclosed an astonishingly large number of men suffering from nervous and mental disease or defect. As compared with other groups of diseases, the nervous and mental group stands fourth in order of frequency, rejection for these causes being exceeded only by rejections classified under diseases affecting (1) eye, ear, nose, and throat; (2) bones and joints; (3) heart and blood vessels." More than 72,000 American youths were found unfit for military service because of nervous or mental disease or defect.

As has been said before, number is not a safe criterion upon which to judge the importance of a public health problem. However, when it is taken into consideration that they indicate broken homes, children adrift, business ruined, promising careers checked, pain, misery, and loss to many thousands more than are actually involved, these numbers alone are sufficiently significant to warrant more attention to the problem than any state, medical school, or health organization

has yet given to it. But there are considerations of a social nature that transcend in importance mere numbers.

Mentality and Maladjustment

The real significance of mental disease lies in the influence it has upon conduct. In the effort we all must make to adjust ourselves to community and social life there are both physical and mental handicaps. The physical handicaps are readily recognized and in most instances easily allowed for; but the mental and nervous handicaps are neither so readily nor so generally recognized and, therefore, are not so easily taken into account. That a man with a defective heart cannot run a Marathon race is recognized by every one at once; that a healthy looking adult with the mental development of a child of seven cannot successfully maintain himself in the community is not so generally recognized. As a matter of fact, many seem still unaware that there is a large group in the community whose mentality is so defective that they must be considered and dealt with as children. Allowance having been made for the unusually bright and the dull, for the sane and the insane, there somehow exists the feeling that all the rest of us are alike and can be counted upon to take our proper places in the life of the community. If one does not find his place, if one fails to maintain himself, if one "kicks against the pricks," it is because he is "lazy," or "willful," or a "fool," or "mean," or "criminal," according to the degree and nature of the failure. This view would not be serious except that society is more or less organized upon it. "This fellow has a strong back. He'll make a good soldier," was the view of a good many army officers until it was brought home to them by experience that a soldier did not fight alone with his back. As well say, "This motor car has a beautiful body. I'll take it."

When it is realized that in the intellectual field alone there is a great variety of quantitative and qualitative difference between individuals, and that these differences exist also in the other mental fields; that a nervous system is not just a nervous system, but its own particular nervous system and that it differs from other nervous systems in its degree of stability and its ability to adjust to different degrees and accumulations of stimuli, then behavior, whether social or anti-social, becomes more comprehensible. The handicap of a slight degree of defect in this field or that field exists for those who find themselves within the broad limits of those called "normal," and these handicaps spell efficiency or inefficiency, success or failure, in varying degrees; but if these

comparatively slight degrees of variation in personality and character traits and intellectual qualitative and quantitative differences can be recognized as handicaps among those who, as "normal," carry on the work of the world, how much more serious must these handicaps be for those who fall without the broad boundaries of the "normal" and into the group of those diseased? If the "normal" at times fail or are inefficient, is it surprising that the "abnormal," contesting in the same event with their tremendously greater handicap, come a cropper and become hazards for the more fortunate?

It is not necessary to theorize upon these matters. The big boy dullard and the big girl dullard, who absorb an inordinate amount of a teacher's strength and time, and thereby retard the progress of the rest of the school, have been known since there have been schools; but, with little to show for her effort except the loss to the other children, the teacher until recently has been hopelessly tied to them. Now it is found that they are feeble-minded, that they have been so from birth, that their development, under the best circumstances, will be limited, and that they cannot progress in a system created for the intellectually normal child. These children are found in all school systems. Those school authorities who are facing the situation squarely and not burying their faces in the sand are now withdrawing these children from the regular grades and placing them in special ungraded classes, with teachers trained in the teaching of the mentally defective. A recent act of the New York Legislature makes the formation of ungraded classes compulsory in any school in which there are mental defectives. This group of children forms one of the most difficult problems in education.

Social Conduct of Defectives

But the dullard does not remain forever in the school. Montague,³ in her study of the children at the Children's Court of the city of New York, reports that 82 per cent of the 1,082 cases examined were classifiable "in terms of deviation from the normal."

Especially significant are the findings in regard to the recidivists, those chronic offenders, even among children, who appear again and again before the court. Of the 268 recidivists examined, 39 were found to be normal; the others were found to be retarded intellectually, feeble-minded, constitutional psychopathic inferiors, psychotic, psychoneurotic, or epileptic. Of even greater significance, probably, are Healy's studies in the Chicago and Boston juvenile courts of the psychopathic and neurotic children.⁴ One should

understand Healy's "boy Jim."⁵ Children, even mentally defective, psychopathic, and neuropathic children, grow up; their handicaps remain the same; the complexity of their lives becomes greater. We meet them again in the reformatories.

PERCENTAGE OF INMATES IN REFORMATORIES FOUND TO HAVE NERVOUS AND MENTAL ABNORMALITIES.

*Women.

Of the inmates in prisons throughout the country where studies have been made, 27.5 per cent are found to be feeble-minded. When the recidivists, the chronic offenders, alone are studied, the percentage of nervous and mental disease mounts so high that it is fair to say that these conditions form the backbone of recidivism. Glueck,⁶ in his study of the admissions at Sing Sing, not infrequently found feeble-minded or psychopathic individuals who began their delinquent careers as children and with repeated incarceration passed through the institutions provided for delinquents of various ages until, in old age or in middle life, they had spent more time inside than outside correctional institutions.

Fernald⁷ points out that a very large proportion of the neglected and dependent children in

the care of the state of Massachusetts are feeble-minded and are the offspring of the feeble-minded; that many of the immoral and diseased girls found in rescue homes and shelters are defective and absolutely incapable of reform or of self-support; that a large proportion of the mothers of illegitimate children are feeble-minded; that a majority of the parents prosecuted by the Society for the Prevention of Cruelty to Children for abuse of their own children are feeble-minded. Studies of prostitutes have invariably shown a high percentage of mental defect and psychopathic conditions.

Recent surveys in various states have shown areas honeycombed with mental defect, communities from which most of the able in mind and body have long since passed out into the world at large, leaving the defective to breed among themselves; foci worse than foci of infection.

As has frequently been pointed out by students of these problems, hereditary pauperism or pauperism of two or more generations of the same family generally means hereditary feeble-mindedness. Families have been studied that have been paupers for many generations, some of their members having been born and even conceived in the poor-house.

Complexity of Neuropathic Problem

The rôle of the psychopathic and neuropathic individual in community life is more difficult to indicate in a brief space than the rôle of the feeble-minded, but it is no less important. Adler's⁸ study of unemployment and personality at the Boston Psychopathic Hospital is suggestive in this regard. Adler concluded:

(1) There are individuals in the community who for a variety of reasons are not able to regulate their conduct on the basis of experience. One of the difficulties that such individuals get into is unemployment. The results of their unemployment bring hardships on themselves and on their dependents.

(2) While some of these individuals show defects of such a severe nature that they may be regarded as hopeless and, therefore, can be segregated, there are others in whom the deviation from the normal is not sufficient to make them incapable of supporting themselves at all times and it is unwise to segregate them and prohibitively expensive.

(3) From our analysis it appears that there are two types of individuals that experience these difficulties. One type. . . . the inadequate and paranoid . . . and the other the emotionally unstable.

Both industry and labor are showing an increasing interest in the part played by nervous and mental diseases in the industrial world. An engineering foundation has recently financed a

study of the effect of these diseases in industry; an important women's labor union has encouraged the organization of a mental hygiene clinic to advise in unadjusted and difficult cases.

Brought from the community by the army draft were a large number of individuals classified by the neuropsychiatric officers as constitutional psychopathic inferiors. Investigation showed that these individuals had never been able to adjust themselves successfully to community life. Trial showed that they were unable to adjust to life in the army. They were discharged, several thousand of them, and returned to the communities from which they had come, where they are now milling on.

Herein, then, lies the importance of nervous and mental disease as a public health problem: not alone in the number slain, though the number is large; not alone in the number of lives crippled and blasted, though the number is larger; not in the burden of expense entailed, though it is enough to give any community pause; but in the damage done to social structure by the struggles at adjustment and compromise of individuals ordained to failure—more often than not failure with consequences more than individual—unless protected and safeguarded by a community manifesting a degree of understanding greater than has ever yet been shown. Infections may be eradicated; nervous and mental disease may be largely reduced in number, though it may not be so readily done away with. But the consequences of nervous and mental disease may be minimized by an intelligent, persistent public health effort.

MODERN MEDICINE IN PRODUCTIVE STAGE, SAYS EDUCATOR

"Productive medicine has supplanted mere curative science, and physicians of today seek to eradicate disease rather than effect a cure after the disease has appeared," said Dr. William Darrach, new dean of the faculty of medicine at the opening exercises of the College of Physicians and Surgeons of Columbia University.

"We are not merely checking disease," he commented, "but we are gaining ground, and though we may not expect to obtain perfect health for all, we are traveling in that direction."

Summarizing the work of medicine in the war, he stated that instead of a loss of weight which resulted from former wars, there was an average gain of ten pounds among the members of the American Expeditionary Force; the weeding out of the unfit brought to light cases of incipient disease in time for their correction. By preventive inoculation, typhoid fever became a negligible factor; tetanus and respiratory diseases were kept at a minimum by means of preventive measures; and prompt treatment of shell shock cases resulted in few protracted cases of war neuroses among the expeditionary forces. Dr. Darrach spoke of the danger of specialization which must be avoided if the best results are to be obtained, for ultimate success depends on unity of effort.

THE PRESENT STATUS OF COUNTY HEALTH WORK IN TENNESSEE

BY E. L. BISHOP, M.D., DIRECTOR, BUREAU OF RURAL SANITATION, STATE BOARD OF HEALTH, NASHVILLE, TENN.

THIE Bureau of Rural Sanitation of the Tennessee State Board of Health consists of a state director, office assistant, four field directors, and lay assistants with the field units.

Financial Arrangement

The source of funds for this work is three-fold, being derived from the State and International Health Boards and individual counties. The funds derived from the State and International Health Boards are used for the salaries and expenses of the field directors and for administration. County funds, supplemented to a certain extent by State and International Health Board funds, are used for payment of lay assistants.

Plan and Extent of Campaigns

Campaigns range in duration from three to twelve months, the length of time being dependent upon county appropriations. The initial work in a campaign is the sanitary survey of the areas selected for intensive health work. This survey consists of a house to house inspection with the

collection of data on the sanitary surroundings, housing conditions, past and present incidence of disease, and other factors.

The units of work in a campaign are as follows:

1. Educational work, consisting of health talks, distribution of literature and individual contact with the people.
2. Soil pollution work, consisting of construction of sanitary privies and the examination and treatment of hookworm disease.
3. Antityphoid vaccine administration, consisting of the free administration of vaccine to all persons desiring it.
4. Medical inspection of schools, consisting of the inspection of all school children in the areas selected for intensive effort.

In counties where a year's campaign is arranged for, two additional units are added.

5. Life extension work.

6. Child and infant welfare work.

The effort is made to assemble and coordinate all available public health agencies in the areas

An insanitary structure which was replaced by double semi-tanks, that have been installed by the Tennessee State Bureau of Sanitation.

These pictures tell the story of what happened to the insanitary privies in the school yard of a Tennessee rural school.

in which work is being done; if possible, the direction of these cooperating agencies is placed in charge of the field director during his stay in the county.

Results to Be Achieved

The extent of this work has been comparatively limited in the past, due to the difficulty in securing county appropriations; but we are now rapidly placing all of our units on an annual basis of operations. Under this plan effort is extended to as wide an area of the county as it is possible to work efficiently over the period of the campaign. When only three months work is provided for, three demonstration areas of from

Two clinics in Monroe County, Tennessee, where 2,882 people were given anti-typhoid serum in three months. Neither picture gives any adequate idea of the number treated in the respective communities during a health campaign.

75 to 100 families each are selected in the county, and effort is confined to intensive operation within the limit of these areas.

The results for which we are striving are: (1) public health education of the masses; (2) stimulation of local interest in public health matters; (3) lower mortality and morbidity rates from soil-borne disease, through the improvement of home sanitation and the administration of typhoid vaccine; (4) the relief and control of uncinariasis; (5) the future establishment of county health departments, to consist of a full-time health officer, and the necessary personnel for the proper performance of his duties.

The Madison County Program

It will be readily realized that it is not always possible to accomplish effectively the results outlined above, due to the failure of local cooperation. We are striving to do some definite work so that we may demonstrate the necessity of county health departments.

In Madison County a program of one year's

duration has been arranged through the co-operation of the county court, which appropriated \$2,400 for this purpose. This sum is to be supplemented by the sum of \$1,500 from State and International Health Board sources, the total of \$3,900 to be used for health inspectors and construction men. The expenses of the field director, for supplies and equipment will be borne from

The road entering the Knobs to Union Hall, crossroads community in Monroe County, Eastern Tennessee. This beautiful but sparsely settled stretch of country suggests the distances residents have to travel to attend the clinics.

State and International Health Board funds. The local chapter of the American Red Cross has appropriated \$3,000 for the budget of an educational nurse director to be attached to our staff in this county, and to do work entirely under our direction. This nurse will be used exclusively in the rural areas of Madison County. Her duties are to make a house to house contact with families, give educational lectures, teach hygiene in the schools, form health leagues, distribute literature, and assist the field director in the administration of typhoid vaccine and in the medical inspection of schools. She will also collect data on the incidence, both past and present, of preventable disease among the persons of the areas in which work is done.

The local nursing agency, the Jackson Visiting Nurse Association, is cooperating with us to the extent of conducting a sanitary survey of the city of Jackson. Otherwise, work in this county follows the routine method outlined, with the exception that we are especially stressing the campaign in this county for the purpose of making it a demonstration county for west Tennessee.

The work in this county is mentioned because of the fact that a definite constructive piece of work was performed, and also because of the fact that the duration of the campaign extended over a period of three months only. The campaign in this county followed the routine method with the

exceptions that administration of typhoid vaccine and home sanitation were especially stressed for the reason that there was an exceptionally high typhoid incidence and a low percentage of hookworm infection in this county.

Illustration was thus obtained of the control of three phases of the typhoid problem, namely: (1) post-epidemic control during the period of a subsequent typhoid season; (2) control of an epidemic at its height; and (3) control of a potential epidemic.

During 1918 in one community of 665 persons there occurred 22 typhoid deaths according to local report, and 16 deaths according to definite record. On June 2, 1919, a field director from the Bureau of Rural Sanitation began work in this area and administered vaccine to 600 persons. He also put carpenters to work building sanitary privies, ultimately constructing these for

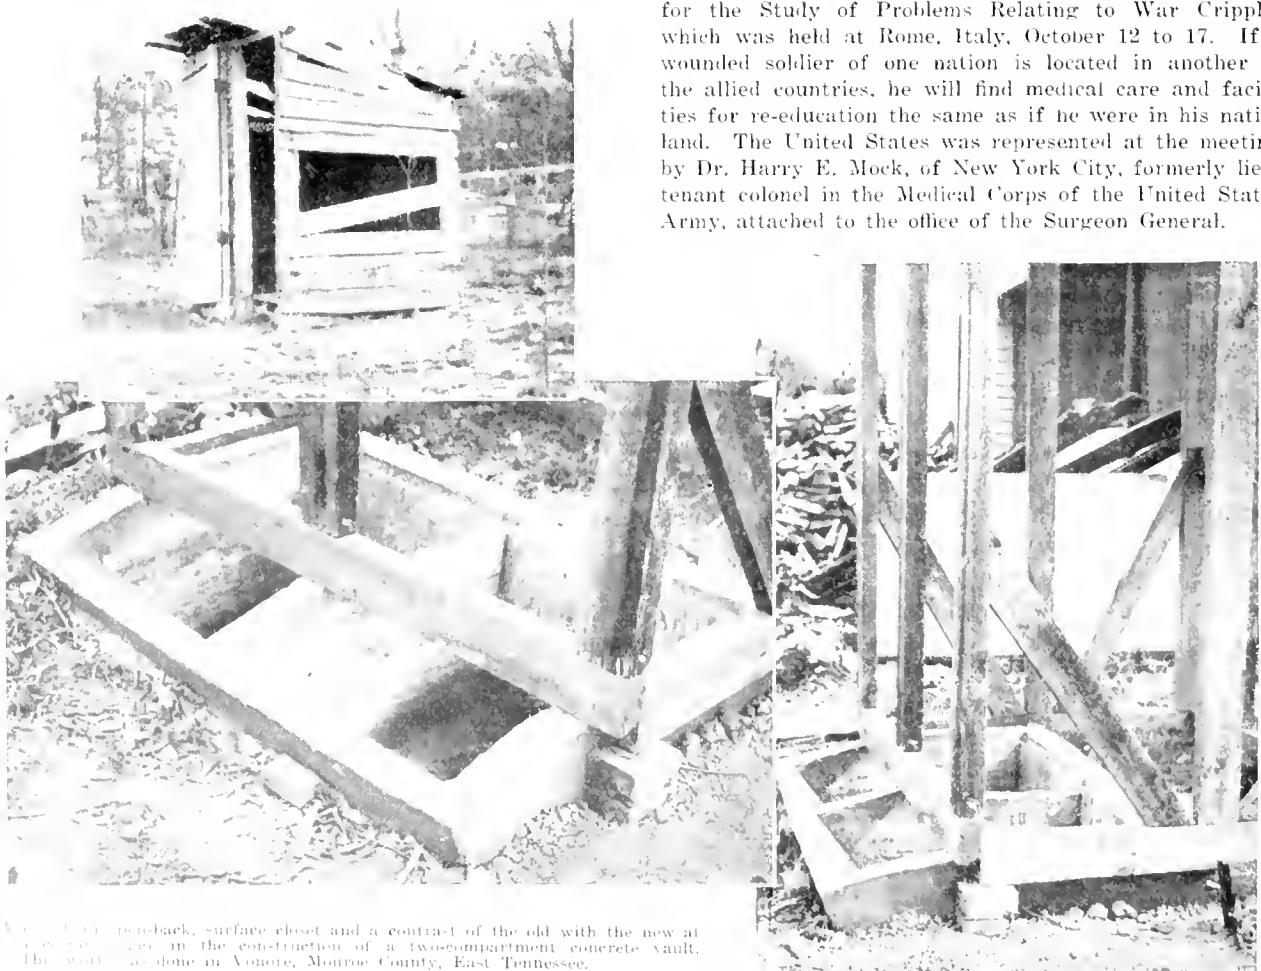

about 40 per cent of the homes, paying special attention to those homes in which typhoid had occurred during the previous year. This season not a single case of typhoid occurred in that community.

In a second community 7 cases of typhoid fever occurred in rapid succession. The administration of vaccine was begun, by the three dose method and, while 5 cases of typhoid developed during the two weeks necessary to administer vaccine, not a single case occurred after the administration of the third dose. Sanitary privies were constructed in this area also, about 30 per cent of the homes being provided therewith. No deaths and no other cases of typhoid have occurred in this community.

In a third community two cases of typhoid fever developed following the visit of a typhoid carrier. Vaccine was administered upon a community-wide basis but no construction work was done, due to the regrettable lack of funds. No other case of typhoid fever has developed in this community.

Interallied Care for Disabled

Arrangements for cooperation in the care of disabled soldiers were made at the Third Interallied Conference for the Study of Problems Relating to War Cripples which was held at Rome, Italy, October 12 to 17. If a wounded soldier of one nation is located in another of the allied countries, he will find medical care and facilities for re-education the same as if he were in his native land. The United States was represented at the meeting by Dr. Harry E. Mock, of New York City, formerly lieutenant colonel in the Medical Corps of the United States Army, attached to the office of the Surgeon General.

THE ANTI-TUBERCULOSIS CAMPAIGN IN OKLAHOMA

JULES SCHEVITZ, GENERAL SECRETARY, OKLAHOMA TUBERCULOSIS ASSOCIATION, OKLAHOMA CITY, OKLA.

THE Oklahoma Tuberculosis Association was organized in 1917. At that time Oklahoma had a population of more than two millions, which represented a tenfold increase over the population of thirty years before. Already this young state was facing the problems of the older states, yet it did not enjoy the protection of a thoroughly organized health administration.

The state tuberculosis association having begun its work on borrowed funds, it was necessary that its first Red Cross seal campaign be conducted in a thorough and aggressive manner. Despite the youth of the Association and the absence of any local organization, the sum of \$40,000 was raised from this source.

Forethought in Expenditures

The first problem of serious import which confronted the Association was the question concerning the expenditure of the proceeds raised from the seal campaign. Should this money be distributed among those communities where seals were sold to be spent by hurriedly organized local committees, or should all the proceeds be retained by the state Association to be distributed to the cities when local health associations were organized, and full time public health nurses employed? The latter course was adopted and the Association adhered to the principle laid down in its Red Cross seal contract, that the most valuable purpose for which the funds could be spent was to build up and maintain a strong and centralized state organization. The wisdom of this move became more apparent as the program of the Association developed.

The promise had been made to a number of communities that they would be furnished with public health nurses. The efforts of the Association to fulfill these promises were almost a complete failure. The enlistment of many public health nurses in war service, accompanied by a nation-wide increase in the demand for such

CAN WE SELL HEALTH TO THE MASSES?

A popular need should create a popular demand, but the whole people never demand a given article without a preliminary educational campaign, followed by consistent efforts to boost the product.

Convince the public that health is desirable, that it is purchasable, that it is largely to be achieved by personal effort, and each man will go after his share.

Shall our physical standards be lowered, or shall we take as our objective that which properly should be the norm of physical prowess?

workers made it practically impossible to secure the type of nurse necessary to commence this pioneer work.

Fearing the patience of these communities was being taxed too severely, the Association set about to relieve the situation by conducting a public health nursing institute for graduate nurses, the course including both field and lecture work, and extending over a period of ten weeks. The course

followed the outline planned by the National Organization for Public Health Nursing. It was understood that the institute was only an emergency substitute for a complete course in public health nursing and was in no case to be confused with the latter. A teacher of long experience was engaged to take charge of the institute; but in spite of all efforts the course was a failure from the standpoint of furnishing the state with trained women who were prepared to carry on effective public health nursing. The nurses enrolled for the course were of mediocre training and lacked the necessary educational background. The facilities for field work were entirely inadequate and the instruction in this branch was unsatisfactory. We learned over again, and in a very forceful manner, that a public health nurse cannot be made in ten weeks.

A Well Balanced Campaign

With this brief review of some of the early experiences of the Association we may proceed to a discussion of its program and policies.

From the beginning those in charge of the direction of the Association felt that whatever the program undertaken, it should be a well co-ordinated, scientifically worked out plan; that the place of each activity should be thoroughly understood, and its relative importance appreciated. This was very important if the Association was to conduct a well rounded anti-tuberculosis campaign and if the proper emphasis was given to the various branches of the work.

Little has been done to work out the relative

values in the anti-tuberculosis campaign. While these experienced in administrative health work appreciate the practical difficulties in conducting a campaign according to any set rules, yet it would be a tremendous advantage to keep a guide of the relative values of the different health measures constantly before us. It would not only pre-

Cover design of the baby pamphlet prepared for the baby welfare conferences. The original is printed in natural colors.

vent undue stress being placed on some comparatively unimportant phase of the program, but, more important, it would enable the workers to plan their campaign with greater precision and definiteness of purpose.

Legislative Campaign

The work in Oklahoma was planned originally to include activities along three general lines: first, the legislative activities including the establishment of sanatoriums, the creation of a Bureau of Tuberculosis in the state health department, and the compulsory reporting of cases of tuberculosis; second, the organization of local health associations, the employment of public health nurses, and the operation of dispensaries; and, third, the prosecution of a health educational campaign to reach all classes of the population.

In the past few years the number of reported deaths from tuberculosis was from 700 to 800 annually, though it was admitted the deaths from this disease were both incompletely and inaccurately reported. Applying the specific death

rate of 150 per 100,000 population to Oklahoma, which is the approximate death rate from tuberculosis in the United States, we should expect at least 3,000 deaths from this disease each year. The Indian population, which in 1910 made up nearly 5 per cent of the population, and the negro element, which is about 10 per cent of the total population, both suffer from exceedingly high death rates from tuberculosis; so the estimate of 3,000 deaths annually from tuberculosis in Oklahoma is probably conservative.

Here was a state with a population of more than two millions, and an annual loss from tuberculosis equivalent to at least three thousand deaths, yet there was not a single public tuberculosis hospital bed available. To make matters worse, the general hospitals were not permitted to admit patients suffering from tuberculosis so that the advanced cases were left to die at home, infecting the children and others about them. The patient having the disease in an incipient stage was likewise able to entertain but little hope for recovery.

No Public Care for the Tuberculous

Three thousand deaths from tuberculosis each year and not a single public bed to care for the many thousand living cases, was the cry raised throughout the state. Finally, as a result of one of the most intensive health advertising campaigns ever waged in the country, the state legislature passed its most progressive piece of health legislation in the sanatorium bill. This bill provides for the construction by the state of two sanatoriums for white people and one for negroes. A bureau of tuberculosis is established in the state health department, the chief of this bureau to be appointed by the state Commissioner of Health. The superintendent of each tuberculosis sanatorium is authorized to have at least one public health nurse on his staff, and is obliged to conduct tuberculosis clinics throughout his section of the state at periodic intervals. The sanatoriums are to be constructed by the state and will be maintained jointly by the state and county. The amount paid by the county is to be fixed by the state Commissioner of Health, within prescribed limits. Each county is authorized to make a special tax levy of not exceeding one mill for the purpose of maintaining patients from its territory in the tuberculosis sanatorium. It will be recognized that this bill contains a complete set of tuberculosis laws in one. The educational campaign which preceded the convening of the legislature included the mailing of 350,000 signed postcards to the members of the legislature and the governor, the sending out of press stories and

boiler plates to all state papers, the use of attractive display advertising prepared by experts in all the large daily papers in the state, the display of lantern slides in all moving picture theaters, the preparation of special literature, blotters, colored poster stamps, and so on. The assistance and co-

state have already been organized in this way and are employing from one to three public health nurses each. There are at least four other counties waiting to be organized when properly trained workers are available. Soon every large center of population in the state will have a local health organization.

It is needless to enter into a discussion of the place of the public health nurse in the anti-tuberculosis and general health campaign. Her actions and accomplishments speak for themselves. The many tributes which have been paid these women are richly deserved. Those who have had the opportunity to observe them work on virgin soil, and to see them bring about a complete transformation in a community from ignorance and indifference to life and interests in the needs of the community, can testify to the value of the public health nurse. From the purely scientific standpoint it is

operation of more than one thousand persons were enlisted in the campaign.

As has already been pointed out, the Association was confronted with a scarcity of public health nurses so that one of the important phases of its activities, the formation of local organizations, was considerably hampered. Here again a vital question of policy had to be decided. Should local organizations be perfected as early as possible, a public health nurse being employed whenever one was available, or should the final organization of local associations be delayed until competent workers could be obtained? In order to avoid the handling of unwieldy and unsatisfactory "paper organizations," it was decided, with the full accord and approval of the communities to be organized, that no permanent organization would be perfected until the employment of a properly qualified worker was assured. After an organization had been perfected the state association was prepared to furnish it with a sum of money, the amount depending upon the proceeds from the local seal campaign.

Eight of the larger cities and counties in the

recognized that the public health nurse occupies the pivotal position in the whole public health campaign.

Through the agency of public health nurses, local health organizations operate tuberculosis and infant welfare dispensaries where patients are cared for according to the best and highest standards. These dispensaries are completely equipped and are in charge of the best trained physician in the community. The excellent work carried on in some of these places has already received the commendation of leading health workers.

In this connection it should be pointed out that even where a health association is not called a public health association,—some are called tuberculosis associations,—all are interested in the general health campaign.

The Oklahoma Tuberculosis Association has always maintained the campaign against tuberculosis is not a campaign against one specific disease, but that it is an effort for the improvement of the public health in general. The educational and special campaigns waged by the city and

county associations are rich in originality and effectiveness but cannot be included here.

Many persons in speaking of the activities of the Association refer particularly to its health educational work. While considerable time and effort have been devoted to this phase of the cam-

A reproduction of the design used on posters and lantern slides for the anti-spit campaign.

paign, there are many other activities which have been receiving the consideration of the Association.

It is interesting to note how much the ultimate success of our public health campaign depends upon the education of the public. Whether our money and efforts are expended in the operation of sanatoriums, the maintenance of dispensaries, or the employment of public health nurses, the main value of these measures rests in the lessons they teach. In order to supplement the educational efforts of these agencies, which must of necessity be limited to certain groups in the community, health organizations resort to numerous methods aimed to bring their message to the attention of the people.

A great deal of time has been given to the careful analysis of educational methods and the relative values of different forms of education. The Oklahoma Tuberculosis Association has repeatedly called in the assistance of experts in this line because public health education, like a great many other things, depends for its success upon the application of certain well defined scientific principles. A disregard of these principles spells inefficient and unsuccessful health education.

In a recent article on "Advertising as a Force in Public Health Education" the author discussed some of the principles to be considered in effective public health education. It was pointed out that the health educational campaign is essentially a selling campaign. The article we offer for sale is health. By the use of sound advertising it is possible to make a health campaign as successful as that of any well advertised commercial enterprise.

A General Publicity Campaign

The educational material prepared by the Association includes nearly every known form of publicity and is in use in one form or another in twenty-five or thirty states in the country. The preparation and display of a series of twelve beautifully illustrated lantern slides, in 150 moving picture theaters in the state was very successful in driving home the principles of correct living, with special reference to methods for the prevention of tuberculosis. Anti-spitting campaigns have been another means of centering the minds of the people on health conservation. These included the use of special literature, posters, four minute speeches, and the publication of feature stories, and display advertising in the newspapers. The recent epidemic of influenza presented another excellent opportunity for imparting invaluable health information, especially advice concerning the after-care of influenza. Display advertising in all the large daily papers was one of the features of this campaign. A reproduction of one of the newspaper advertisements is shown. The sanatorium campaign al-

**After the "flu"
is over---**

The after effects of influenza are oftentimes more serious than the disease itself. It is highly important that those who have had influenza should take every precaution to bring their bodily resistance back to normal as quickly as possible.

After recovery the room that has been occupied during the illness should be thoroughly renovated—not with sulphur candles, formaldehyde and other so-called fumigants, but with lots of soap, water and "elbow grease."

Let in plenty of fresh air and all the sunlight possible.

After you have had influenza, your body is weakened and it is much easier for you to contract respiratory diseases such as pneumonia, bronchitis and tuberculosis.

Tuberculosis is one of the most dangerous after effects of influenza and great care should be taken to prevent the occurrence of this serious disease.

Prevent Tuberculosis

Remain in bed for several days after all fever has subsided.

Do not return to work until all symptoms have disappeared.

Make special effort to rebuild the body's resistance by taking plenty of wholesome nourishment and by keeping in the open air as much as possible.

Be sure that your sleeping room has lots of fresh air. Outdoor sleeping is even better.

Give the body more than the accustomed amount of rest.

If you cough or have purulent sputum for more than two weeks, go to your physician for a careful examination to see whether any signs of tuberculosis are present.

Tuberculosis is both preventable and curable. If detected early enough, before the disease is far advanced, it can be arrested or cured.

Don't use patent medicines.

For further information or advice, consult your physician.

Oklahoma Tuberculosis Association

A reproduction of an advertisement which appeared in nine daily papers during the influenza epidemic of 1918.

ready mentioned was a most effective educational drive and every group of the population was reached in a particular manner. Other forms of health education in common use such as newspaper stories, editorials, feature stories, lectures, moving pictures, and institutes, have all been used as part of the educational program.

educational attempts of the Association. Contrary to similar publications the *Pow Wow* is quite attractive and readable. The attention given to the selection of type and preparation of layouts are noticeable in the finished product. The *Pow Wow* is always well illustrated, contains news of the health campaign in Oklahoma, and

Three panels selected from a thirty-six panel exhibit conducted by the Oklahoma Anti-Tuberculosis Association. Each panel is hand-painted, is beautifully colored, and illustrates one central idea. The slogan, "Prevent Tuberculosis," appears on each panel.

A large exhibit on tuberculosis prepared by the Association is perhaps unique in this country, in attractiveness and in the information it imparts. The exhibit consists of a series of handpainted panels, beautifully colored, each containing one picture designed to illustrate one central idea. The panel contains two or three lines of descriptive matter at the bottom, but the well planned illustration is mainly responsible for the message.

The Children Enlisted

The Modern Health Crusade movement may also be considered a part of the general educational program. Here, too, advertising was made use of, in enrolling the children in this movement and in keeping up interest. As a result of consistent publicity more than 200,000 children in the state were enrolled. This branch of the work has become so heavy that a special worker has been assigned to devote full time to school educational activities. "Rhymes for Health Crusaders," a twenty page pamphlet printed in three colors, illustrating the simple health chores and containing clever jingles for each chore, is one of the contributions of the Association to this movement.

The publication of a monthly house organ, the *Oklahoma Pow Wow*, having a wide distribution throughout the state, represents another of the

deals especially with the problems facing our local workers.

Child Welfare Activities

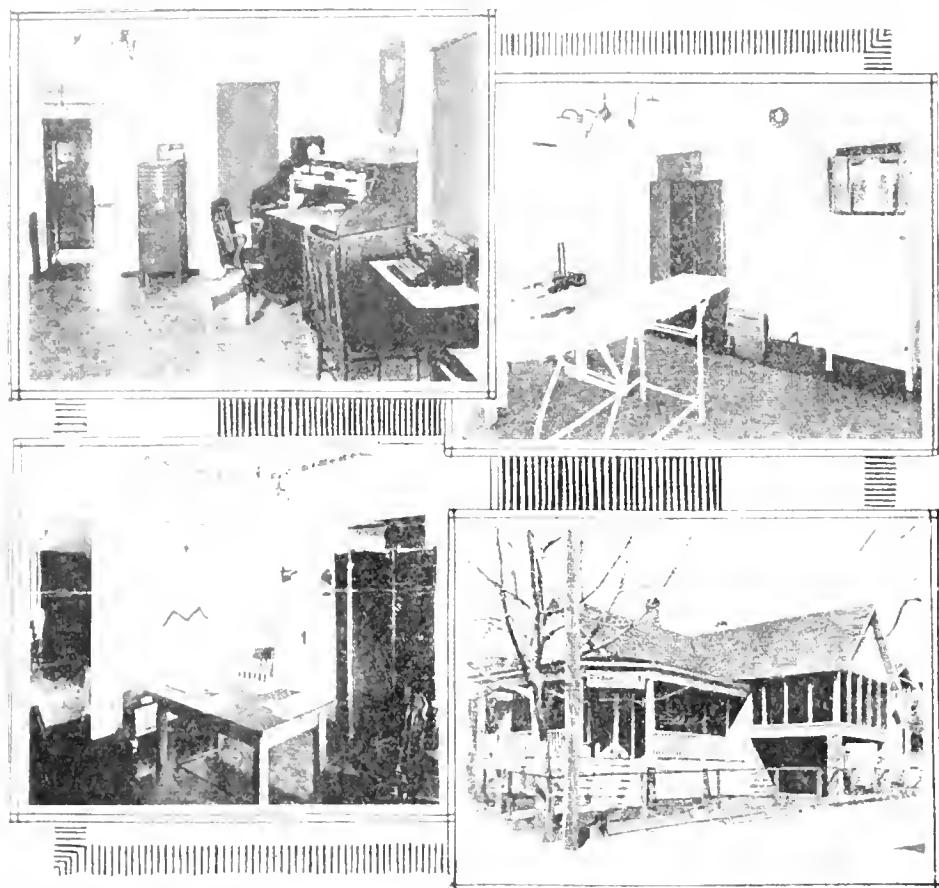

At least two efforts, the infant welfare campaign and public health surveys, have received a great deal of the Association's attention which may be challenged by some as having little or no bearing on the anti-tuberculosis campaign.

The child welfare work carried on during the summer of 1919 will be continued until cool weather sets in, and resumed early in the spring. This work is in the nature of a demonstration, only a month being spent in a county. The original plan was to have at least three nurses on our staff giving full time to this work, but up to the present time only one nurse has been secured.

The routine followed in arranging for these baby conferences is simple and effective. Two or three weeks before the infant welfare nurse is expected in the county, a member of the field staff of the state Association visits the county and organizes local arrangement committees. With the help of these committees a suitable location for the demonstration is selected, the services of local physicians are enlisted, and funds are obtained to defray the living expenses of the nurse. About a week before the first conference this local committee begins advertising in the newspapers, and

at the same time sends out a double post card to all mothers in the vicinity. The names of the mothers are obtained from the local registrar of vital statistics, and also from the members of the committee who generally have personal acquaintance with the mothers. In this post card the mother is told of the baby conferences and is asked to sign and mail the return card if she de-

foods, and pasteurization of milk. In addition to a very complete set of attractive exhibit panels which bedeck the walls of the examination, demonstration, and waiting rooms, there are numerous models which portray the lessons in a graphic manner. An inexpensive bed where the baby can sleep alone and be thoroughly protected against flies has been especially prepared for

Views of the office, examining room, waiting room, and exterior of the tuberculosis dispensary maintained by the Tulsa Tuberculosis Association.

sires to have her baby examined. Upon receipt of this return card by the local committee an appointment card is mailed to the mother, and she is advised on what day to bring her baby to the clinic. This makes it possible to divide the examinations evenly over the entire period of the demonstration.

Health Demonstrations Made Interesting

On the Sunday preceding the first examination day, announcements of the examinations are made from all pulpits and from that time on publicity is carried on consistently by lantern slides in the picture theaters and distribution of attractive hand bills to each home.

The conference consists of a thorough medical examination of all babies, with demonstrations of bathing, feeding the baby, the preparation of

these demonstrations. The town furniture store exhibits a sample refrigerator; the drug store generously displays an outfit consisting of babies' toilet articles, bottles, brushes, and so on. A model exhibit containing the clothing babies should have, giving the prevailing market prices, is also displayed at the demonstrations.

Aside from participating in the examination of the babies at the demonstrations, the nurse spends a part of her time visiting babies in their homes and calling on mothers who are unable to bring their babies to the clinic for examination. In these visits the nurse has excellent opportunity to impart valuable pre-natal instruction.

A great deal of helpful literature is distributed at the demonstration. An attractive booklet containing valuable information concerning the care of babies during the first year of life has been

prepared and is being received with great enthusiasm by the mothers. This booklet, known as "My Baby," has a beautiful cover design printed in many colors and the text is illustrated in color. Accompanying the booklet a special height and weight chart for babies up to thirty-six months old has been printed. This chart allows for the insertion of the baby's weight and height so that they may be readily compared with the standards. Both pamphlet and chart are distributed in large numbers by more than one hundred registrars of vital statistics, who use them as inducements to mothers to have their babies' birth registered.

Public Health Surveys

The Association has always felt that these efforts in the saving of child life are one of the best paying investments it can make. It feels that such child welfare work may be considered good anti-tuberculosis work.

In a large measure improvement in the health of any city, state, or nation is dependent on the knowledge and understanding of the existing conditions. Reforms based on speculation and doubt are less likely to result in permanent benefits than improvements brought about by careful and scientific analysis.

As an organization vitally interested in the public health of the state of Oklahoma, the Oklahoma Tuberculosis Association ever since its inception has felt its great work was to ascertain the exact status of the factors affecting the health of communities all over the state and, with this data at hand, to attempt to arouse the state and local officials and the public at large to the importance of greater interest in the public health. The mere enactment of legislation, the expenditure of additional funds, or the employment of trained workers, is of little avail unless it is accompanied and supported by intelligent and powerful public opinion.

Analyses of Vital Statistics

Both objects have been kept in mind in conducting the public health surveys of urban Oklahoma. Even before the actual publication of the first report the benefits to the communities and state have manifested themselves in ways sufficient to convince the Association that its efforts will be well repaid.

Subjects considered in the surveys included an analysis of the vital statistics; an investigation of the water supply; the sewage disposal; a study of the methods of the collection and disposal of refuse; measures pursued for the control of the milk supply; thorough study of housing conditions; a

careful analysis of school hygiene and sanitation; inspection of foods in stores, markets, lunch rooms, and restaurants; a study of the organization and activities of the local health department; and an analysis of the city budget.

These surveys have been conducted in a thorough manner during the past two years in eight of the largest cities of the state under the direction of M. P. Horowitz of the Department of Biology and Public Health, Massachusetts Institute of Technology. They are unique in that they represent the first effort that has been made to ascertain the health conditions of a state as a whole. The publication of these reports is already in progress and will be a valuable contribution to the science of public health.

Other Activities

In conclusion it might be well to point out some of the other interests of the Association. A colored minister has been employed to give full time lecturing among the negroes of the state. A nurse who has spent a great many years among the Indians is being engaged to give her efforts to the health work in the Indian schools on the reservation. A medical field secretary, who is a specialist in the diagnosis of tuberculosis, will be employed to act as consultant to the physicians of the state.

Every three months the Association conducts a public health nurses' conference and at these meetings, which generally extend over two days, the nurses receive considerable instruction along practical lines and are given an opportunity to discuss local problems and exchange ideas. A state public health conference for all interested in public health is held every year, and this conference is used as a means of carrying on intensive health advertising throughout the state. This conference was very well attended in 1918 and the second conference, to be held September 23 and 24, 1919, will undoubtedly be even more successful.

The officers and executive committee of the Association make up one of the most faithful and hard working groups of its kind in this country. In the state organization as well as local organizations the most prominent and influential persons give their active personal support to the Association, and much of the progress of the anti-tuberculosis campaign may be attributed to the most excellent cooperation and assistance offered by these interested persons.

FARRAND NAMES TOBEY ASSISTANT

James A. Tobey, recently connected with the New Jersey State Department of Health, has been appointed assistant to Dr. Livingston Farrand, chairman of the Central Committee of the American Red Cross.

FRAMINGHAM DEMONSTRATION REPORT

[Extracts from report of committee on appraisal for the Framingham Community Health and Tuberculosis Demonstration.]

THE officers in charge of the Demonstration have accepted what appears at present the soundest current viewpoint, that the most effective practical procedure for the control of tuberculosis lies in the development of machinery for its early detection and for the hygienic care of individuals affected or threatened with the disease—while at the same time taking such opportunities as offer to minimize the spread of the infectious agent. The first step along this line must be a determination of the actual prevalence of tuberculous infection, and this end has been accomplished with a high degree of success by the organization of medical examination drives, by the organization of a tuberculosis consultation service, and by the establishment of infant, school, industrial, and other clinics. Efforts along this line have been strikingly successful in giving us for the first time a fairly complete picture of the amount of tuberculosis actually existing in a typical American community.

The conclusion that in the medical examination drives nearly 1 per cent of the persons examined were suffering from active tuberculosis, while somewhat over 1 per cent more were arrested cases, is an important one. This finding, if assumed to be representative of the whole community and compared with the death rate for the town, would indicate a ratio of 9 or 10 active cases during the year to one reported death. The best way to estimate this factor would, in our judgment, be to compare the number of active cases under observation during a given year with the number of deaths occurring among that group of cases. The actual experience of the Demonstration has been that two hospital beds have been required for each reported death; but the period is too short and the number too small to warrant far reaching deductions. Furthermore, it should be noted that it would have been difficult to fill this indicated ratio of beds without the effective machinery for locating cases at the disposal of the Demonstration. On a basis of the active advanced cases in which the need for hospitalization was most acute, the ratio indicated by the Framingham experience would be nearer one bed to each reported death. The careful analysis of death certificates showing that the actual deaths from tuberculosis in Framingham were 22 per cent in excess of the reported deaths from this disease also constitutes a valuable contribution, although the small number of cases involved makes it impossible to apply this conclusion in any general way.

In connection with the problem of diagnosis, the officers of the Demonstration have prepared a scheme of diagnostic standards for tuberculosis which has attracted wide attention. Most important of all the practical contributions made by the Demonstration is the working out of a plan for medical consultation service which is clearly the most promising means yet devised for securing a reasonably complete knowledge of the amount of tuberculosis existing in a given community. This work has been carried on by Dr. P. C. Bartlett with admirable scientific skill and exceptional tact and judgment. The physicians of the community almost without exception avail themselves freely of this service and, aside from the direct results in the detection of early and doubtful cases, the stimulating effect upon the local medical profession constitutes an invaluable service to the cause of public health in Framingham. The consultation service plan has attracted wide attention throughout the country and under the auspices

of the State Department of Health and the State Tuberculosis League such a service has been offered for three months in the Cape Cod district of Massachusetts with great success. The plan is already in operation, or is proposed, in sections of Illinois, New York, Ohio, Oklahoma, Vermont, and Wisconsin.

The success of this organized campaign for the discovery of tuberculosis is indicated by the fact that nearly 200 cases are now under observation in Framingham as compared with 27 at the beginning of the Demonstration, and it is particularly encouraging to note that during the first year 42 per cent of the new reported cases were of an advanced type, while in the second year only 16 per cent of the cases were advanced, and in the first five months of 1919 only 23 per cent.

The machinery adopted for the treatment of cases of tuberculosis after they have been discovered has been modeled along generally accepted lines, involving sanatorium treatment, or hygienic advice furnished through the service of a public health nurse, as circumstances may dictate in the individual case. There has been nothing here that is particularly novel, but the work has been accomplished efficiently and successfully along the lines indicated by the best current practice.

* * * *

The object of the gift made by the Metropolitan Life Insurance Co. to the National Tuberculosis Association was not, as we understand it, primarily to benefit Framingham or any other local community, but to determine the practicability of the control of tuberculosis by the full application of the best known methods. The really important question before your Committee is not, therefore, the extent to which Framingham has benefited by the development of an admirable scheme of local health organization, but the degree to which this organization has been effective in controlling tuberculosis. Success along this line might obviously be measured in two ways, by a decrease in new cases, or by a decrease in the tuberculosis mortality. With the progress of the Demonstration and the improvement of machinery for finding early cases, the recorded morbidity at first materially increased; but it is interesting to notice that during the first five months of 1919 only 40 new cases came to light, as against 55 new cases for the corresponding months of 1918. Obviously, however, no conclusions can be drawn from this isolated comparison. From the standpoint of mortality, the tuberculosis death rate, after eliminating non-residents, and adding deaths of residents occurring outside of the town, has fallen from 93 per 100,000 in 1917 to 79 in 1918, and to a rate corresponding to 76 for the first five months of 1919. This is an encouraging showing, in view of the fact that the tuberculosis death rate in similar Massachusetts communities has in general materially increased; but again the period is so short and the actual number of deaths so small that no reliable conclusions can be drawn.

The member of your committee representing statistics (E. T. S.) has prepared a computation of the probable errors involved in the problem and concludes after fitting the rates for 1917-1916 to the curve of probable error, and allowing for mean error in any given rate projected for 1919-1923, that in order to warrant reasonably safe conclusions one or the other of the following combinations of tuberculosis death rates must be reached during the latter period: A rate of 30 or less for any 1 year; a rate of 45 or less for any 2 years; a rate of 60 or less for any 3 years; a rate of 75 or less for any 4 years; a rate of 90 or less for all 5 years.

It is obvious that rates between 70 and 80 for 1918 and 1919 cannot possibly be considered as significant, and it could scarcely have been expected in dealing with a disease of the nature of tuberculosis that any conclusive results could be reached in a period so short as three years.

* * * *

It seems clear that if the Framingham Demonstration should cease on January 1, 1920, the local community will have benefited materially and many important contributions will have been made to the practical control of tuberculosis; but that the main question for which the Demonstration was endowed will remain unanswered. In the judgment of your Committee this would be a most unfortunate contingency. Our best authorities on tuberculosis have been subject during the past few years to a growing skepticism in regard to the adequacy of methods which have been advocated for the control of this disease and have turned eagerly to the Framingham Demonstration as the first real opportunity to set their doubts at rest. If the Experiment should be abandoned at this time it would be necessary to begin all over again somewhere else, for a test of the best methods now available is absolutely essential for future progress in this field.

If on the other hand it should be possible to continue the Demonstration for a sufficient period to yield results of statistical accuracy, your Committee feels confident that the question as to the soundness of the current anti-tuberculosis program will be definitely answered one way or the other. The foundation has been well laid; a program for the control of tuberculosis by early diagnosis and hygienic care has been organized on ideal lines; local sentiment both in medical and lay circles has been successfully developed in support of the campaign; and all conditions are favorable to its success. Given a sufficient period for the continuance of the Demonstration and for the study of the results obtained, both morbidity and mortality records should furnish a clear answer to the question of whether or not such a program is effective.

In addition to the fundamental conclusion as to the practicability of the control of tuberculosis by the methods used in Framingham, a continuation of the Demonstration should throw important light upon the theoretic factors which contribute to the development of tuberculosis as a disease, and should therefore make it possible to modify our program along more purposeful lines in the future.

The investigations made at Framingham have as yet led to no far reaching conclusions in regard to these factors. The most suggestive point that has been brought out is perhaps the variation in disease incidence among different race stocks. The combination of a very high proportion of tuberculin reactions with a low mortality among Italians and the precisely opposite condition among persons of Irish race stock is of considerable significance. The study of the subsequent history of the large number of arrested cases now under the observation of the Demonstration constitutes, in itself, an invaluable opportunity to determine some of the factors which convert latent into active disease.

In the continuation of the work of the Demonstration, we would urge that special attention be paid to the intensive study of environmental conditions, in the home, the factory, and the community, with a view to throwing more light than has yet been obtained upon the possible effect of each condition upon the spread of tuberculous infection and the development of active disease. We are inclined to believe that the detailed study of even a few hundred cases should yield results of real value in this connection—if correlated with observation of the en-

vironmental conditions surrounding a properly selected control group of families free from tuberculosis.

* * * *

The statistical calculations cited above have led us to the conclusion that the Framingham Demonstration should be continued for a period of at least five years in order to render the attainment of definite results of reasonable certainty. It is, of course, possible that the prolongation of the Demonstration experiment through 1922 might be accompanied by a tuberculosis death rate of 60 or less for all of the 3 years involved; but since a death rate of 60 corresponds to only 12 deaths, it is obvious that a chance combination of circumstances might easily interfere with such a result. In this contingency we should once more face the possibility that a large sum of money had been spent without the attainment of the primary object in view.

The effect of such an experiment should be cumulative, and each year added to its life greatly increases the chances of ultimate success. A five-year period should, we believe, yield results reasonably certain to answer the question as to the practicability of the control of tuberculosis. If successful, it would furnish for the first time a definitely established working program for the practical control of tuberculosis. If unsuccessful, it would indicate with equal clearness the need for the adoption of measures of a different sort from those that have recently been recommended as adequate and necessary.

* * * *

(1) Your Committee feels that the work of the Framingham Community Health and Tuberculosis Demonstration during the past three years is worthy of high praise. It has organized and carried out a community plan for the control of tuberculosis along the lines indicated by the best modern scientific knowledge. It has given us the first reliable information as to the actual amount of tuberculous present in a typical American community; and in the organization of a tuberculosis consultation service it has made a contribution of the first magnitude to the machinery of public health protection. In addition, it has stimulated the development of the general public health campaign in Framingham to a degree that goes far toward realizing the highest ideals of modern sanitary science.

(2) The Demonstration has not furnished an answer to the primary question as to the practicability of the control of tuberculosis, because the period of three years was necessarily too short to make a conclusive answer to this question possible.

The results thus far obtained are as promising as could be expected under existing circumstances but an extension of the work for a period of five years more will be necessary in order to insure with reasonable certainty a satisfactory answer to this question.

(3) Your Committee, therefore, recommend that a further appropriation of \$100,000 should, if possible, be obtained for the continuance of the Demonstration experiment along the general lines indicated in the body of its report.

HEALTH CENTER FOR WOMEN AND GIRLS OF NEW YORK CITY

By FLORENCE MEREDITH, M.D., Director, New York City

The Health Center was established in July, 1919, with the object of conservation of health among women and girls. We have gone one step further even than prevention of disease by emphasizing the maintaining of health, a positive thing, rather than the avoidance of disease, a negative thing. We deal with individuals entirely, by means of a complete physical examination, prescribed rules for the individual girl's health, prescribed exercise to promote general health, to bring about good posture, strong feet, symmetrical development, and free circulation, and definitely to prevent such minor but significant maladies as constipation and dysmenorrhea. We also prescribe and provide facilities for suitable recreation planned to suit individual needs.

The public can be interested in public hygiene and in such forms of individual hygiene as are carried out among babies and children. Adults, however, have had largely to put up with the interest of the medical profession in their individual cases only when they had fallen ill, and this often through wrong ways of living. We are trying to prove that well people are not so heedless of health that they can not be interested to learn to live right and keep well as doctors have supposed; and that the time and money and effort spent in this teaching of personal hygiene are profitable both from the point of view of individual wellbeing, and social and economic prosperity.

We are experimenting for the first time with the great problem of health education in its individual application among adults. Any woman who works in any line is examined and advised free of charge. We are teaching them that unless they feel entirely fit, free from big or little discomforts, not only living along but getting joy out of living, unless they have a body to be proud of, yes, even unless they are good to look at, their health is not what it should be, and this is probably due not so much to their heredity or their environment as to their individual habits of living.

Once they have acquired this point of view,—that a good deal of their health is entirely their own responsibility and that, even if perfect health is not possible, they should at least endeavor to attain their own maximum,—we find them eager to follow the advice given. They are given report cards and required to indicate from week to week whether they have done what was recommended. They have cooperated, without exception to their own advantage. This proves to our satisfaction that the public is ready for health education, and that it is the duty of the medical profession to supply it.

THE PUBLIC HEALTH NURSE

The August issue of the *Public Health Nurse* is the annual report number. It sets out the general aims of the National Organization for Public Health Nursing, discusses reports of the several committees' achievements during 1918, and outlines the program for 1919. Perhaps the most important activity of the Organization is their efforts toward establishing improved public health nursing standards and in providing educational courses calculated to furnish an increased supply of qualified executives and teachers and staff workers. The formulation of standards is a matter of extreme difficulty and will be satisfactorily arrived at only by the concerted efforts of trained workers and by a comparative study of their surveys. Cooperation, centralized organization, and stand-

ardized training of workers will go far toward making this possible. Other contributions in this issue are as follows: "Is a Visiting Nurse a Public Health Nurse?" by Elizabeth G. Fox; "Work of the Public Health Nurse in Italy," by Mary S. Gardner; and "Study of Public Health Nursing in Westchester County," by Zoe La Forge.

INFLUENZA MORTALITY AMONG WAGE EARNERS AND THEIR FAMILIES

The statistical methods employed by the life insurance companies in many regards furnish the best perspective available on the more prevalent diseases. A most valuable contribution of this character is the recent contribution by Lee K. Frankel and Louis I. Dublin, of the Metropolitan Life Insurance Co., published under the above title in the October issue of the *American Journal of Public Health*. From many quarters much discussion of the influenza epidemic of last year is being published, some of it based on accurate observation, some of it speculative, but none of it deduced from so large a number of cases as are considered in this contribution. The deductions are based from 105,552 policy claims paid among over 12,000,000 policyholders, representing a total of 70,729 deaths from influenza-pneumonia. On the basis of death rates per 100,000 years of life from influenza-pneumonia norms of incidence are established upon which are calculated the percentage rates during the recent epidemic. Classification is made according to sex, race, age periods, and geographic distribution. Comparison is made between these rates and death rates during the same period from non-influenza causes. It is pointed out that these results are not conclusive as a longer period will be necessary to adduce data as to complications following the epidemic, and increased death rates in such disorders as Bright's disease which may be consequent upon the epidemic. Later reports of the further analysis of these data will be awaited with interest.

THE PUBLIC HEALTH JOURNAL

The September number of *The Public Health Journal* contains the presidential address of D. L. Cruikshank, M.D., of Windsor, Ont., before the Medical Officers of Health of Ontario. Without minimizing the importance of such issues as providing for the care of defectives, of instituting measures for the control of epidemics, and the proper study of the causes of diseases, Doctor Cruikshank charges the medical officer with his chief duty in explaining to the people the care of the human machine; for, when all is said, specific immunization is based upon "the self-healing power of the body." Rest, food, fresh air, and sunlight are the slogans of health.

The paper of S. E. L. Thompson argues the same defects of health administration as obtain elsewhere and his chief emphasis is placed upon the laxity of enforcement of public health laws, the need of full-time health officers, the importance of paying adequate salaries, and endowing them with the power to make their edicts effectual.

A resumé of the general policies discussed at the American Red Cross Conference at Cannes is given by Sir Arthur Newsholme in "Work of Red Cross Organizations in Relation to the Preventive Medicine of the Future."

Other articles are as follows: "Some Opportunities for Health Service from a Volunteer's Point of View," by Miss Helen R. Y. Reid; "A Plan for a More Effective Federal and State Health Administration," by Frederick L. Hoffman; and "A Preliminary Study in the Bacteriology of Jellied Meat," by J. A. Allen.

PROBLEMS IN SOCIAL MEDICINE

Medical and Health Education, Child Welfare, Social Insurance, Rehabilitation, Medical Law and Allied Subjects

JOHN A. LAPP, LL.D., Editor

MEDICAL CARE OF STUDENTS

MODERN MEDICINE publishes in this issue two articles on medical and health service for students in Columbia University and Tuskegee Institute. These supplement the articles in the October issue on the medical service of the University of Wisconsin, and the state-wide service of the University of Iowa. Additional articles on this kind of service will appear with some regularity in this magazine.

The subject is of paramount interest to the workers in preventive medicine, to the physicians as a step in cooperative group medicine, and to the sociologists as a means of protecting and conserving human powers and talents.

Judged from the point of view of the individual student, these plans for medical service make good insurance for him. It is much better to pay a definite fee, where a fee is required, and be certain that whether sickness comes in light or serious form his medical care is already provided for, rather than that he should bear the uncertainty and expense of an extended illness.

Not infrequently students, especially those who are working their way through college, are handicapped for years and perhaps prevented from completing their education by the burdens of a single sickness. The payment of five, six, or ten dollars a year by all students in a large group gives an insurance against any sickness no matter how extensive. From the standpoint of the physician this service gives a unique opportunity for organization for tending and preventing sickness *en masse* on a social basis. It also gives the opportunity for group practice and enables the development of 100 per cent medical service to a whole student body.

To the sociologists this service must make an appeal because of its conservation of educated talent. By the time students reach the college

or university there is a large investment of money in each student. There is also a development of talent which has been carefully selected and nourished.

The best interests of society are conserved by education, and education cannot be efficient in its results without physical and mental powers. The adoption by colleges and universities as well as secondary schools of the plan to give complete medical and health care to all of their students, should encourage us to look forward to a new era in the development of human power and talents. The ideal, as expressed by Doctor McCastline, University Medical Officer at Columbia, "does not differ, perhaps from the object of health service of other institutions throughout the country. It is so to organize our service that it will be possible for the student to gain a knowledge of his physical characteristics, of any tendencies toward, or immediate conditions of ill health. During the time that he is at the university we attempt to determine his physical defects and deviations from a reasonable health standard, to correct these conditions where possible, and to assist the student to develop habits of exercise, rest, and recreation as will make him as normal mentally and as efficient physically as it is possible with his inheritance."

"All men are not born with physical powers of equal strength, with like endurance under pressure, with the same resistance to communicable diseases, with like speed and accuracy of muscular coordination. . . . It is only by the observation and study of the individual that we are able to time him and to regulate his periods of work and recreation so that he may reach the pinnacle of his efficiency as a constructive worker in society and, while giving out his 100 per cent of work, also enjoy happiness through health and its attendant enthusiasm."

EDITOR.

DR. CHARLES A. PROSSER

DR. CHARLES A. PROSSER has resigned as director of the Federal Board of Vocational Education to assume his former position as director of the Dunwoody Institute of Minneapolis.

Dr. C. A. Prosser, Director, Federal Board of Vocational Education.

lis. In his departure from the Federal service the country suffers a distinct loss.

Doctor Prosser had done many noteworthy services in the cause of the common man before the war, but his greatest service has been since the war began in planning and organizing the work of vocational rehabilitation for the Federal government which is now putting wounded men back on their own independent feet as working members of the community. Before men were scarcely more than dreaming of the possibilities of vocational reconstruction, Doctor Prosser was formulating plans for Congress to take care of the injured men on their way back to employment. The law was passed, the experience of the warring nations was gathered, the entire Canadian process of reconstruction was studied personally by Doctor Prosser, and an administrative organization was built up throughout the country to meet the emergencies which war might throw upon it. In no branch of the Federal service was the work or organization performed with a clearer vision of the end in view.

The early closing of the war, happily, made unnecessary some of the plans originally formed; but the growing humanitarianism of the country

caused a broadening of the existing program. To-day the larger part of the wounded have been examined and those entitled to re-education have been placed in schools.

The task has been a difficult one. The program was new, with no American experience behind it. The demagogues were at hand to make the wounded discontented. The politicians carped, and then scuttled. Jealous departments and bureaus threw obstacles in the way; and yet, the idea of sound rehabilitation prevailed.

Few men served the country more constructively in difficult work than Doctor Prosser, and the work he did has laid the foundation for a new movement of far reaching power for good,—the rehabilitation of cripples in industrial and civilian life.

MENTAL CLINICS IN UTAH CITIES

The establishment of a series of mental clinics in the various cities in the state of Utah this winter is being planned by the Utah State Board of Insanity. Next summer the work will be extended to the outlying sections. The plan is based on the theory that early attention to mental and nervous disturbances will prevent conditions which may necessitate commitment to an asylum. A complete census of the feeble-minded of the state will be taken. Psychologists of the University of Utah will assist both in the clinics and in the survey.

TUBERCULOSIS SURVEY AT SARANAC LAKE

A tuberculosis survey of the residents of Saranac Lake, N. Y., conducted under the auspices of the Edward L. Trudeau Foundation, bears out what progressive health officers and sanitarians have repeatedly urged—that there is a minimum of danger of infection of healthy adult residents of resorts frequented by tuberculous patients. According to the weekly report of the United States Public Health Service, the Saranac survey showed that indigenous morbidity and mortality from tuberculosis are low, only 0.3 of 1 per cent of the living cases being found among the native born, and 0.9 of 1 per cent among previously healthy residents. This is in accord with investigations in other places and should be of assistance in overcoming unreasonable prejudices regarding alleged dangers from proximity to tuberculosis sanatoriums.

REGIONAL TUBERCULOSIS SECRETARY

Mr. Arthur J. Strawson has been appointed by the National Tuberculosis Association as Regional Secretary for the Mississippi Valley district. The district comprises the eleven states included in the Mississippi Valley Conference on Tuberculosis. He assumed his duties on August 1, and opened the district office, 627 Pythian building, Indianapolis, Ind. Mr. Strawson was executive secretary of the Indiana Tuberculosis Association for two years and prior to that was with the Illinois State Tuberculosis Association. For the past eighteen months he has been in the Home Service Department of the American Red Cross. The appointment of Mr. Strawson occasions the statement by his associates that he will be able to give valuable service to the coordination of the work within his territory.

COLUMBIA UNIVERSITY HEALTH SERVICE

BY WILLIAM H. McCASTLINE, M.D., UNIVERSITY MEDICAL OFFICER, COLUMBIA UNIVERSITY, NEW YORK

THE HEALTH service at Columbia University was instituted in the spring of 1912. Until this time there was no organized department definitely responsible for this important phase of medical work. The department of physical education was carrying on a constructive program of health education among those who were compelled to take gymnastic courses and athletics. These men were carefully examined and were given programs of exercise, etc., to meet their needs. The physicians in the department treated, also, all emergencies and accidents that occurred in the gymnasium and on the athletic field; but no attempt was made to treat the diseases of students of the University. President Butler felt that the University's duty did not begin and end with its academic and social activities, but that the University should do all in its power to keep its students efficient through health while at the institution, and should create, during the period of academic training, such a regard for health that the students would cherish it as a part of their university experience and live and work in such a manner after they had gone out into their chosen fields of activity as to maintain through health their physical and intellectual efficiency.

Conserves Potential Workers

In the spring of 1912 this new department for health service was organized with the object of giving the students the opportunity to put themselves under medical supervision and treatment when necessary. The University Medical Officer gave his full time to studying the individual health problems of the students. Every effort was made to divorce the medical supervision from the undesirable attributes of an institutional organization. In choosing a site for the office and in furnishing it an effort was made to develop a setting that would make the student forget that he was being treated as a member of a large insti-

A SOUND MIND IN A SOUND BODY

The Health Scheme at Columbia contemplates giving the graduate a stamp of physical health and efficiency in keeping with the standards of education upheld by the University.

No student is graduated without fulfilling the compulsory credits in physical education.

On the basis of four years of medical supervision, with a complete annual physical examination, his margin of safety as to work, rest and recreation is determined. The student is thereby fitted to live and work so as to maintain his health and intellectual efficiency.

puny, sickly body was considered a perfectly normal heritage for a trained intellect; but now the man with a body below par is at a distinct disadvantage in the race for success in any field of work. The universities of the country stand as an investment for the equipment of men with trained minds to fill the positions in the fields of government, finance, and business, where initiative and endurance are the "take-offs" or the foundation qualities that advance civilization and bring added happiness to the world. It is a poor investment to put so much valuable material at the command of any student, if at the same time we are not preparing, in a scientific way, his physical body so that he may have at the completion of his college or university training sufficient health and physical vigor to carry the weight of his responsibilities as a skilled worker.

There is still another aspect to this health problem. Given the opportunity to judge a problem, or to initiate a professional, political, or business project: unless the one who undertakes it is in good health, the degree of his success will be limited and tinted by his lack of energy, by his myopic or astigmatic outlook, made less effective because of ill health. These facts and many more have become evident to the men who make a business of education. At Columbia we are endeavoring to put into operation a scheme that will give the graduate a stamp of physical health and efficiency that will be in keeping with the standards of education upheld by the University.

The object, therefore, that we have set for

tution. The object was rather to make him feel that he was in the office of his private physician.

The university students are potential workers destined to occupy important positions in the business, professional, and political life of our country and no effort is too great nor any financial outlay too large to make them a healthy, strong, energetic, well trained physical and mental force.

The time was when a

ourselves at Columbia does not differ perhaps from the object of the health service of other institutions throughout the country. It is to so organize our service that it will be possible for the student to gain a knowledge of his physical characteristics, of any tendencies toward or im-

In Earl Hall is the centralized health department which acts as a clearing house of all matters concerning the health of the student life at Columbia University.

mediate conditions of ill health. During the time that he is at the University, we attempt to determine his physical defects and deviations from a reasonable health standard, to correct these conditions when possible, and to assist the student to develop habits of exercise, rest, and recreation that will make him as normal mentally and as efficient physically as it is possible with his inheritance.

All men are not born with physical powers of equal strength, with like endurance under pressure, with the same resistance to the communicable diseases, with like speed and accuracy of muscular coordination, similar temperaments, etc. Their physical characteristics are as varied and as numerous as the individuals themselves. It is only by the observation and study of the individual that we are able to time him and to regulate his periods of work and recreation so that he may reach the pinnacle of his efficiency as a constructive worker in society and, while giving out his 100 per cent of work, also enjoy happiness through health and its attendant enthusiasm.

Future Health Requirements

At Columbia University we have a staff of physicians and nurses to treat ambulatory illnesses. The University maintains this service free of cost to the student. It is supported by a yearly budget maintained by the trustees. It is our hope, however, that we may be able to raise an endowment fund for the support of the health work.

There is no more important branch of preventive medicine and no more important phase of university endeavor than this work which aims to develop health in the individual by curing, as far as possible, acute and latent disease; to help the student to realize and measure his physical limitations; and to find for himself health and physical comfort.

The treatment of acute and chronic diseases, of emergencies and of convalescent cases is carried on for all university students who wish to take advantage of the privilege. We aim to make the students appreciate the necessity of early treatment and the importance of a thorough physical examination when any condition arises that seems to be a deviation from the normal or usual state of health. During the past seven years, thousands of students have made use of the opportunity afforded by the University to obtain medical advice and treatment. In the university office on the campus alone, during the past three years, from ten to twelve thousand medical consultations have been held annually without expense of the students.

The type of medical work that we are developing at Columbia is along the lines of constructive preventive medicine that considers not only the diagnosis and treatment of the immediate illness, but seeks to take into account present and future difficulties and to foresee their bearing upon the student's health and success. We take into consideration the general state of health and phys-

The waiting room in the Health Department at Columbia University accommodates twenty-five people. At one end of the room is the office of the secretary who handles all questions and requests, makes all appointments, and attends to all the records of the department.

ical make-up of the patient; the importance of his responsibilities as a student so that he may not lose any more time than is necessary; the type and character of his work in its bearing upon his present and future health. We seek to prevent

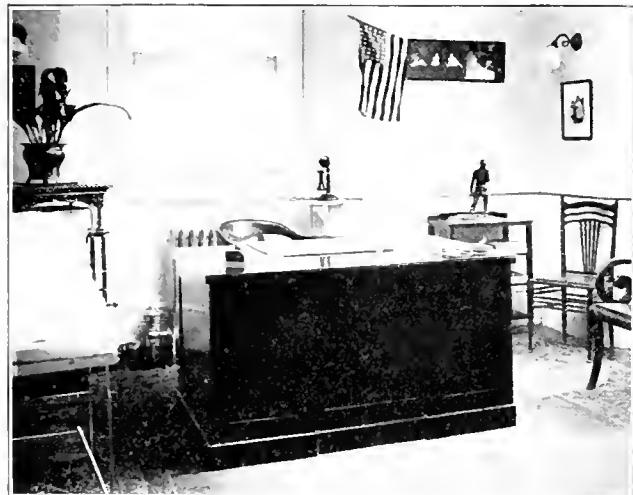

any sequelae or any permanent handicaps that might result from the treatment of symptoms without the removal, in so far as possible, of the cause of the student's illness. If from a medical standpoint our services are to be of value to the man who plans a life of useful activity, we must consider all of these points and many more. The reason that society today is wearing a coat of many colors, cut, fitted, and tailored by quackery and "isms," is that physicians of scientific training have not yet given enough thought to the future experiences of the patient while treating his immediate illness.

If we can educate men and women to appreciate the importance of health and to recognize the part played by scientific constructive medical practice in reaching this goal, we will do for society more than law can accomplish in protecting the people of our commonwealth from being duped by quacks and superstition.

Essentials in Health Supervision

In developing our health service work at Columbia, we have attempted to keep in mind the following vital points:

- (a) The right of our students to select their own physicians for medical and surgical treatment.
- (b) The rights and privileges of the private physicians in the vicinity of the University campus.
- (c) The economic waste of duplicating

The consultation rooms of the Health Officer create the atmosphere of privacy so desirable if the student is to feel free to avail himself of the privileges of the all round medical care provided at Columbia University.

equipment, etc., that can be used in an organization of this kind and that is already effectively working.

- (d) The value of so organizing the scheme that it will bring into play all available

sources of assistance that will make the organization complete and easy of operation.

(e) The elimination of red tape in the office administration.

(f) The consideration of all data collected in the office of the University physician as

The nurses' office and general conference room at Columbia University opens with four examining rooms, an arrangement which makes possible the expeditious handling of several patients at once.

strictly private and under the absolute control of the physician in chief.

(g) The use of the student body as a co-operative community to develop sanitary conditions that will assist in maintaining health.

(h) The making of the individual the center of our intensive study rather than the student body as a whole, since group regulation is of secondary importance if the individual can be controlled.

(i) The importance of faculty cooperation in assisting in this program of individual health promotion.

(j) The development of a type of medical supervision that will appeal to the student so that he will continue to apply the principles of preventive medicine to his life after leaving the University.

Conditions Peculiar to Columbia

We have had in mind also the fact that Columbia University is situated in the center of a great metropolis. Our 20,000 students live scattered over an area whose radius is from twenty-five to fifty miles from the campus. Our dormitories accommodate only a small proportion of our students; hundreds live in private families, in hotels and boarding houses; hundreds live at home. We must meet these conditions effectively rather than attempt to follow a scheme of organization found successful in the colleges and universities situated in small towns or in the suburbs of large cities.

With an attempt to meet these conditions, Columbia's organization is as follows: On the first floor of Earl Hall, one of the most attractive and centrally located buildings on the campus, we have equipped a suite of rooms for the University Medical Officer. The suite consists of a large, bright, sunny, well ventilated reception room, accommodating about twenty-five people. The room is large enough to permit of plenty of space between the chairs so that it is not necessary for a patient to be in close contact with his neighbor. This room is furnished attractively with hard wood and smooth leather, so that it may be easily cleaned and kept free from dust. At one end of the room is the office of the department secretary. The secretary's office acts as a clearing house for the questions and requests of the students, members of the faculty, and outsiders. A record of all requests, suggestions, and complaints regarding individuals, sanitary conditions of buildings, etc., on and off of the campus, community problems, etc., is kept and brought to the notice of the University Medical Officer. The secretary makes all appointments for special examinations, and attends to the correspondence and records of the department.

The medical work is carried on in a suite of eight rooms. The nurses' office and general conference room opens into four examining rooms; two set aside for general examinations, a third for dental examinations, and a fourth for the examination of the eyes, ears, nose, and throat. The other three rooms are equipped for medical and surgical treatments, including special equipment for the treatment of the eyes, ears, nose, and throat. This arrangement makes it possible to handle several cases at once. In these offices we have a staff of three physicians and two trained nurses. This is the medical center for the treatment of all university students, exclusive of Barnard and Teachers' College students.

Provision for Women Students

At Barnard, the women's college of the University, we have a second medical center in Students Hall. This building is the social center of Barnard College and contains a gymnasium, special exercise rooms, a swimming pool, rest room, social rooms, studies, and a large restaurant.

On the second floor of this building, the health service department has a well equipped office for the care of the women students of Barnard College. The office suite consists of a reception room, a nurse's room, three private dressing booths, a physician's office equipped for examinations and treatments, also a well equipped room for the minor surgical treatments and for the examina-

tion and treatment of the eyes, ears, nose, and throat. Office hours are held daily and a careful scheme of health supervision of the Bardard students is carried on by a woman physician and one nurse. The plan of work is essentially that which will be described for the men.

In each one of our dormitories we maintain an infirmary for the treatment of illnesses occurring among the residents of the respective dormitories. In each of the women's dormitories we have a resident trained nurse.

The Handling of Cases

When a student reports to the university medical office for treatment, he fills in a numbered

yellow slip, giving his name, his address, the school of the University in which he is registered, and, briefly, the object of his visit. These slips are deposited at the secretary's desk and the patients are called in numerical order, except in cases of emergency or of severe illness when they are seen immediately by one of the physicians. This method insures each patient a definite place among those waiting and he may, if not too ill, busy himself with his writing or studying, knowing that when the time comes for his treatment or conference, he will be summoned. The morning hours, from 9:30 until 12:30, are given over to general office practice. The afternoon hours, from three until six are set aside for the exami-

nation and treatment of special cases and for appointment work that would take too long for the general office hour. From nine until six someone is always on call in the office for emergencies. All medical work done in the office is free to the students. Up to the present time no charge has been made for bandages, plaster, laboratory tests, etc., or for medicines given to students at the office. When drugs are necessary in the routine treatment of cases, these drugs are prescribed and the prescriptions filled at any drug store that the patient may elect.

The University Medical Officer has the privilege of sending students to the Vanderbilt Clinic for diagnosis and treatment, when for some reason the patient cannot be handled satisfactorily at the university office. This is one of the largest and best equipped clinics in the city and is under the direct supervision of the College of Physicians and Surgeons, the medical school of the University.

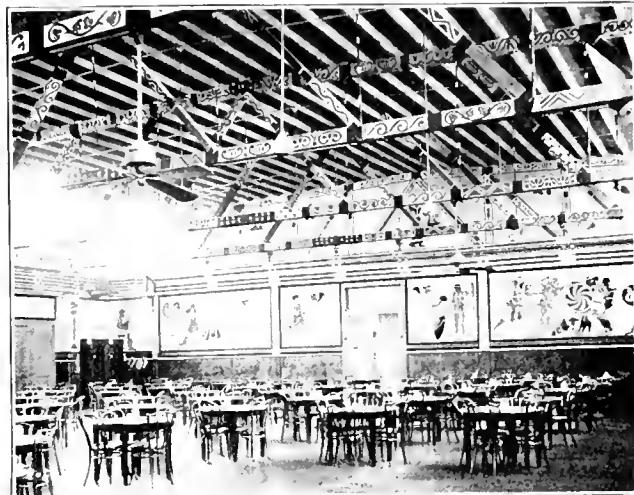

Upon the staff of advisers to the University Medical Officer are specialists in every field of medicine. These men stand ready at any time to advise the University physician on cases that fall within their special provinces.

The University does not maintain a general infirmary for bedside work. During the past seven years, experience has proved that our cases are very satisfactorily cared for in the hospitals of the city. New York City is doubtless one of the greatest hospital centers in our country, and it would be financially impossible for the University at this time to build a hospital large enough to accommodate the medical and surgical cases of a student community of over twenty thousand that would measure up to the standards of our large hospitals. Seriously ill cases are sent to the various hospitals of the city. In these institutions they have the benefit of excellent hospital organization, with laboratory service, well established nursing departments, and the careful attention of the resident medical staff and the expert supervision of the attendants.

From an economic standpoint it would be unwise for Columbia to attempt to duplicate the equipment of the excellent hospitals at our door, even if we had the financial means to do so. Our ultimate plan is to endow a Columbia pavilion in one or more of our hospitals when we can secure the gift to make it possible. If the University were not in the midst of the greatest medical center in the world, it would of course be necessary to maintain on the campus a general infirmary for bedside cases. Mild cases confined to their rooms are treated by local physicians. Through the visiting nurse the department seeks to coope-

rate with the private physicians in the care of students ill and living in the vicinity of the University.

With the facilities for early treatment and supervision at the university office, the number of

In order to make the scheme of supervision complete, the Trustees of Columbia University have taken over the University Commons. An up-to-date sanitary kitchen is provided and no effort is spared to provide the best quality of food, well cooked and well served, at a price to cover the cost, but no profit.

seriously ill cases among our students has been greatly decreased. The majority of our cases in the surgical field are for the correction of conditions in order to secure improvement in health; and the time and the place for the operation are fixed to meet the pleasure of the patient and the convenience of the surgeon. Most of our acute cases, both medical and surgical, are sent to St. Luke's hospital. The hospital property adjoins the University campus.

One phase of our work is perhaps unique and I feel is a step in the direction of real preventive medicine. With the opening of the academic year 1919-1920, all students in the undergraduate schools of the University will be placed under careful medical supervision. During the four years of their college life, a record will be kept of their physical condition, as shown through complete annual medical examinations, records of illness, grade of class room work and quality of work done in the department of physical education.

With these records as a basis for judgment, the University Medical Officer will be able to advise the student and assist him to gain a knowledge of his health condition that he could not otherwise have. Fortified with a definite knowledge of his state of health and with an understanding of his margin of safety as to work, rest, and recreation, he will with greater certainty be in a position to make the most of life as a man who is destined to success because his actions are governed by a

reasonable understanding of his physical life and his environment.

When a prospective student makes application for admission to Columbia College, he is required to file, with his credentials of scholarship, a personal history of his present and past health together with a medical examination form filled in by a doctor of medicine, preferably the family physician, after the physician has made a complete physical examination of the applicant. The report of this medical examination is filed with the University Medical Officer. If there is recorded by the examining physician any condition of importance that might handicap the applicant in his social, physical, or scholastic duties, he is required to consult the University Medical Officer before completing his registration. Thus all cases in need of immediate attention are placed under medical supervision before college duties begin.

At the beginning of the freshman year and annually thereafter as long as he is a student in Columbia College, each student will receive a complete physical examination under the supervision of the medical director of the University gymnasium. These examinations are made by a staff of physicians and are as complete and comprehensive as were the examinations for the Officers' Reserve Corps during the war. Detailed records are kept of the conditions found, tabulated in such a way as to make it possible to follow the development of the body and the state of health of the student from year to year. A photograph of each freshman is taken to record general posture and physical defects. In cases where postural defects are evident a photographic record may be made at stated intervals to show progress resulting from corrective or special gymnastic work. Copies of all these records are filed with the University Medical Officer.

All students who show abnormal conditions will be required to consult the University Medical Officer or some member of his staff. When necessary, treatments, either medical or surgical, will be given. Upon the completion of the annual examination, a card will be issued to all students who show conditions needing medical attention. The card is issued as a means of giving official notice to the parent or guardian of the student's need of treatment. The student must present this card, properly signed by parent or guardian, to the University Medical Officer within one month of the date issued, showing that the student is under the treatment of his own physician or that he desires the treatment given under the supervision of the University Medical Officer.

After acute illness, the student will be placed under medical supervision for a reasonable period

to make sure that no condition develops that might insidiously undermine his future health. Students whose scholarship falls below standards that should be maintained will be placed under medical observation and will be given special examinations to ascertain if the cause of poor scholarship is due to physical conditions. If ill health is found to be present, treatment will be instituted and the student will be given an opportunity to make good his grade.

In order to make this scheme of health supervision complete, the University Trustees have taken over the University Commons, that for many years has been leased to outside corporations. No health program of this kind can be successful unless it is possible for the students to obtain a variety of food of good quality, well-cooked, and attractively served. The Trustees have at considerable expense refurnished the kitchen and remodeled the dining room so that we now have an up-to-date sanitary kitchen and an attractive Commons. No effort will be spared to make the Commons serve the purpose for which it is maintained, that of serving to our students and patrons the best quality food, well cooked and well-served, for a price that will cover the cost without any attempt to make a profit.

As a means of keeping in touch with problems that affect the student health but which might well be overlooked by the medical staff, a student board of health has been in operation since 1912. The members of this board are appointed by the University Medical Officer and, as far as possible, every school of the University is represented.

In order to establish habits of exercise, and health of body through physical activity, the Director of the Department of Physical Education, Prof. George L. Meylan, has developed a system of physical education that will be compulsory for all students throughout the first two years of college work. Every student will be required to take part in the athletic and gymnastic work. In the fall and late spring the work will be on the athletic field; during the winter months, in the gymnasium. Students who have any physical conditions that make it impossible for them to enter into the general physical education program, will be organized in special squads or will be given individual attention. No student is graduated from Columbia College without fulfilling the compulsory credits in physical education. The instruction in hygiene is given as part of the compulsory work in physical education.

The Health Service Department and the Department of Physical Education cooperate in making the medical and hygienic supervision of the undergraduates effective.

HOW TUSKEGEE INSTITUTE IS PROMOTING BETTER HEALTH CONDITIONS IN THE SOUTH

BY JOHN A. KENNEY, MEDICAL DIRECTOR, JOHN A. ANDREW MEMORIAL HOSPITAL, TUSKEGEE INSTITUTE, ALA.

OF THE MANY departments established at Tuskegee Normal and Industrial Institute, Tuskegee, Alabama, it is doubtful if any one has proved itself of greater worth and real benefit to the community, or even to this section, than the department of health. In establishing this department in the beginning, the idea was to care for the sick students of the school; also, those of the teachers who were not connected with the school families and were housed in the dormitories. In the beginning it was necessary to educate not only the students, but the teachers to the hospital idea. This took a very long time, longer than might be supposed in an institution of this kind. For several years it was rather rare to have a teacher as an inmate of the hospital, many preferring to remain in their rooms for treatment because the name "hospital" carried with it a certain odium that was more or less repugnant to the average teacher.

A COMPLETE HEALTH UNIT

Organized to care for only the sick in the school, Tuskegee Institute now maintains annual clinical meetings for the advancement of medical science, a training school for nurses, a general hospital, free medical and surgical care for the indigent, and home nursing service.

In five years 6,828 medical cases have been treated, with a mortality of only 0.4 per cent. Surgical cases to the number of 379 were treated with a mortality of only 2 per cent. During the same period the out-patient department handled 9,532 treatments, including many minor surgical operations.

from such persons saying: "Turn my son or my daughter out of that 'horse-pittal.' "

As the idea became more popular among the teachers and the student body it was found to be a good thing to extend its benefits to our immediate community; that is, to the town of Tuskegee and then to Macon County, for the care of persons who were not officially connected with the school. This necessitated another educational effort. For a long time it was difficult even to get such people to come within the doors of the hospital, and to say to them, "remain for treat-

Nurses at work in the hospital garden of the John A. Andrew Memorial Hospital.

ment," was sometimes considered almost an insult.

We are pleased to say that these conditions now have very largely changed; but we are still engaged in the effort to educate our people to the hospital idea.

Various methods have been used to do this. One of the best, of course, is to get a patient from a certain community; give that patient the best of treatment at our disposal; get good results; convert him, and send him back home. Such a patient becomes a walking advertisement and is a means of getting a number of others from that section. This is sometimes done purely on a charity basis for some needy individual. At other times the

sult that we have never suffered for lack of material. Our Eighth Annual Clinic was held the first week in April of this year at which time we had present seventy physicians and surgeons, including a few dentists. The Clinic was divided into four departments—medical, surgical, dental, and a special clinic for eye, ear, nose, and throat diseases. At this clinic there were treated 290 patients, 40 of whom received surgical operations.

Because of the many advantages offered to the patients and to members of the profession by these annual clinics, it was decided last year to form a permanent organization and hence was formed the John A. Andrew Clinical Society with a membership of fifty-one. The object of this so-

The first Boys' Hospital, Tuskegee Institute.

opportunity arises in the regular course of hospital service.

Several years ago it was thought a good idea to hold clinics at the hospital for the purpose of giving both medical and surgical treatment to such cases as needed professional care but were unable to pay for the same. In 1912 the National Medical Association held its annual meeting at Tuskegee Institute, and it was thought that this would be an opportune time to inaugurate the clinic. Arrangements were made and the results were all that could be wished for. Fully 525 patients were treated on this occasion during the Clinic Week. These were given medical and surgical treatment. A variety of operations were performed. All of the patients recovered and went back to their individual communities, since which time we have held a clinic annually with the re-

society is to perpetuate and hold the annual clinics at our hospital and, while treating the many needy patients, to encourage the development of our physicians, surgeons and dentists by placing at their disposal the amount and variety of work these patients afforded for study, observation, and treatment.

Our hospital work had a very humble beginning when in 1892 certain rooms in one of the girls' dormitories were set aside for the female students who were sick and certain rooms in the boys' dormitories for male students who needed medical attention. A female physician was employed and a certain number of boys and girls were assigned to her to help her care for those who were sick. This was the real beginning of our hospital and of our Nurses' Training School. A little later one of the cottages on the grounds

was set aside for the purpose; in 1901, friends of the North provided funds for the erection of a two-story frame hospital building. The work continued in this until 1913 when other good friends of the North donated funds for the erection of the John A. Andrew Memorial Hospital, a modern, up-to-date, well-appointed, two-story brick building, with accommodations for sixty patients with no crowding, and for a good many more when it is necessary.

Our Nurses' Training School has kept pace with the growth of the hospital and the nurses have proved themselves a real boon to suffering humanity all through our immediate section, and practically throughout the South in different cities

distributed free of charge among the people of the community. Nurses are sent out into the homes of the needy to do district work, giving baths, cleaning up homes, preparing nourishment for the sick, and showing them how to do these things properly for themselves. By these means the Health Department of the Tuskegee Normal and Industrial Institute has grown until it has become a real factor in the social life of this section of the South.

Our nurses played their part nobly during the epidemic of influenza last fall and winter, as a number of testimonials which space will not permit us to use, would show. The following figures will show the amount of work done outside of the

The present John A. Andrew Memorial Hospital—Erected in 1913.

and towns, and in many places in the North. We have in our possession a number of communications both from and concerning our nurses which show what they are doing in private work, in institutional work, in the public health service, and in nearly every instance they are able to hold their own along with graduates from other institutions. Up to the present time we have graduated 127 nurses and a large number of undergraduates have left us with sufficient training to enable them to administer successfully to the sick and to secure constant remunerative employment.

It is our purpose as far as possible to make the Institute Hospital the health center not only of the school but of this community and, with that object in view, from time to time health talks and demonstrations are given by members of the hospital staff both at the hospital and at appointed places in the community. At frequent intervals literature bearing on health conditions and giving simple rules for health betterment is printed and

hospital by the nurses from September 1, 1918, to June 1, 1919, and reveal the great demand for their services and the fact that they fill a much needed want in this section: Thirty-seven nurses served 1,061 days in 104 homes in twenty-six towns.

As an index of the amount of work that is being done at this hospital, note the following extract from a report of the medical director made at the Second Annual Meeting of the John A. Andrew Clinical Society in April at which time the Trustees of the School were present:

"In the past five years, we have treated in the wards of the John A. Andrew Memorial Hospital, 6,828 cases. Of this number 379 received surgical operations. While we do not believe the mortality rate of a hospital is the exact index of the work, yet at the same time it is a customary method of measuring a hospital's efficiency. Out of a total of 6,828 cases treated in the past five years in our wards and private rooms, we have lost 28 patients. Among our operative patients

from a total of 379, we have lost 8. During the influenza epidemic we had in our wards 449 cases of influenza with 32 cases of pneumonia. We did not lose a case of influenza and only one

of pneumonia. In the out-patient department during the past five years up to 1918-19, we have given 9,532 treatments which included many minor operations."

THE WORK OF THE VISITING HOUSEKEEPER

BY EVA K. MARKMAN, R.N., JEWISH AID SOCIETY, CHICAGO

"VISITING housekeeping! What is it?" I asked when the suggestion came that there was an opening for work of this nature at the Jewish Aid Society. "It's hard work," came the response, "but combined with your experience as a visiting nurse, you can develop its various phases as you see fit."

After two and a half years of pioneering work as an instructive visiting housekeeper, it is still difficult to state our aims. Each new case brings new problems; the instructing visiting housekeeper goes to the home primarily to improve existing conditions and to raise the standard of housekeeping, the idea being that when cleaner homes are the rule and better methods of housekeeping are adopted, we will have better mothers and healthier babies.

The first lesson firmly impressed upon the mothers is that the home is for protection; that a successful mother implies that she must be more than a good cook and seamstress. She must be an efficient manager as well as a capable mother, and must learn that it is her big job to rear her children properly, and to prevent disease.

To manage well the mother must teach each member of her family to accept certain responsibilities, and it is the duty of the instructing visiting housekeeper to see that these responsibilities are carried out. The mother is first taught to keep her home clean. By example and simple explanation she then learns to cook the proper kinds of food, and this brings with it the ability to reduce the cost of living by discriminate buying. From a hygienic standpoint, the mother is also given instruction in personal care, as well as proper attention to her household duties.

THE WORK SPEAKS FOR ITSELF

The home environment that is unwhole-some and unlovely the Visiting House-keeper seeks out and corrects.

This is done, not by her own efforts, but by supplying the incentive and showing the way to self-help.

She gives a meaning to humdrum duties and awakens enthusiasm for the day's work.

This constitutes the best kind of preventive measure in health work. Does it not also involve a spiritual regeneration? So then the womanly aid and sympathy of the Visiting Housekeeper becomes a therapeutic agent.

The average mother with whom she works is uneducated, and has a low standard of what constitutes cleanliness. On her initial visit a survey is made of the family and it is impressed upon the mother that the visiting house-keeper will work with her to secure the desired results with the best and simplest methods. The mother soon comes to the belief that the plans developed for the improvement of conditions

in the home as well as in the children are her own, and that the calls of the visiting house-keeper are made merely as a general supervisor who understands the particular requirements of that home.

The people must be met on a ground of equality to gain their confidence. With mutual understanding ties are formed which are strengthened with each visit. No two families can be cared for in the same manner, nor do all families readily accept the instructions. One of the great difficulties to overcome is to break down the barriers of the deeply rooted traditions of the past. While the kosher kitchen is strictly maintained, little by little foods which are most nourishing are introduced to the family table, primarily a greater amount of staples instead of black bread and herring. Almost without exception in such homes, cereals have been an unknown article.

Incentive Must Be Created

Many families who are contented in their environment of squalor must be aroused to a realization of their condition and what it means to their future. To stimulate the desire to improve present environment, they must learn that help is being held out to them, but that they must work for it themselves.

In new cases, where the mother is not physically able to do the cleaning and has absolutely no conception of how to start, a colored maid whom we have trained, goes out with the visiting house-keeper and the family is given its first lift. We start from the farthest corner of the home and go carefully through it. Old clothes stored away for years, representing gifts of friendly but short-sighted benefactors, are found, sorted, and properly placed. If possible the rags are sold. In homes where the mother is ill and is making a great effort to raise the standard of living, the maid does the laundering once a week. She becomes very much interested in the families and cooperates in every detail.

A practical housekeeping center has been equipped in the administration building of the Jewish Aid Society, where mothers' classes meet each week. By simple explanation and practical demonstration, the mothers are given lessons in cooking and food values, discriminative buying, and proper preparation of foods. Instruction is given in personal care from a hygienic standpoint, and each mother is taught to write her name in English. In some instances it has proved to be a stimulus for further instruction in the public school. That the mothers may learn the importance of discriminative buying, they are taken direct to the store and their purchases supervised. Afterward they are allowed to go alone, and they profit and gain self-confidence by the mistakes made in their purchases.

Reach Community Through the Home

One mother has so readily responded to all instruction that she is now able to teach her neighbors how to keep clean and to cook and bake. She shows such good judgment in her buying that she acts as chaperon to her neighbors in their shopping expeditions. These trips are usually made on sale days and, if she deems the sales worth while, the purchases are made with greatest care. This work has brought to her a heretofore unknown happiness. Despite her busy life, involving countless duties, she has learned the real joy of giving and is always ready to lend a helping hand.

A mothers' club has evolved from the cooking classes and the spirit of friendliness and cooperation which the mothers evince has been one of the most gratifying features of the work. There is a keen interest in the cooking demonstration in each home, where the work is done with the cooking utensils at hand. Each mother watches the progress of her neighbor and tries to carry out in her own kitchen the demonstrations given in the homes of the others. "Company for the first time

in fourteen years," one mother said when the class met at her home. The instructive visiting house-keeper exerts her greatest influence in the home itself.

The most important obstacle to be overcome is in effecting an entire change in the attitude of the mother toward her home, her family, her kitchen, as well as every part of her house. The same holds true in clothing: simple standards must be taught. When the mother is convinced that clothes plainly made are in better taste and launder more easily, much has been accomplished.

Play Helps the Work Along

Nor is recreation overlooked. Mere words are inadequate to express the appreciation and enjoyment of the mothers at the little affairs and outings given for them throughout the year. At our parties mothers were entertained with Jewish songs and many were able to join in the choruses with an enthusiasm which must be seen to be understood. For the first time in years, many of the mothers have been privileged to dance to real music. They were then invited to go to a moving picture. They enjoyed talking about this event beforehand quite as much as they enjoyed its actual realization, and to be invited to sit through a performance at the Jewish Theater was a treat about which they never even dared to dream. We go in a body as a mothers' club, and their conduct at these affairs is a thing to be proud of.

Nor is the work of benefit only to the mothers. Although it has often been disheartening, even from the most difficult cases, much has been gained. The strong bonds of friendship formed through the many visits of trials have been of great mutual stimulus; and the spontaneous acts of gratitude of the mothers, expressed in the eye as well as in action, have more than compensated for the frequent discouragements. It is this personal contact with the mother that inspires the instructive visiting house-keeper and helps to bring about the desired result. A deep sympathy with suffering humanity is essential, but it must be untinged with sentimentality. Firmness must be combined with tenderness, and, above all, the instructive visiting house-keeper must learn to act quickly and tactfully. The path is strewn with many disillusionments, but the psychological moment is sure to present itself when tangible results become evident.

A Case in Point

The following is an example of the intensive work done with one family:

The family consisted of a lazy, indifferent fath-

er; a careless, slovenly, sarcastic mother; and seven children, ranging in ages from 8 to 14 years, all tuberculous, except the youngest. The father, mother, and oldest two children had had sanatorium care. After the father was released from Oak Forest, he was placed in a newspaper stand, where he worked nine hours a day, averaging about \$12 per week. Four of the boys worked spare moments, outside of school hours, at the newspaper stand and newspaper routes. The father did his work unwillingly, believing he was too sick to work. His income was inadequate for the family, and the Jewish Aid Society lent its support. The family lived in four gloomy rooms, occupying mainly the two filthy rear rooms, where they were huddled together, a most unhappy lot. They resented any intrusion and brusquely told the visiting house-keeper to leave them alone, as they would get along the best they could.

The parents were at the "don't care" stage. The mere suggestion that the wife do her own baking brought consternation to father and mother alike, for the husband could not understand that his sickly wife should undertake the task. After three rebuffs there appeared a faint gleaming of acquiescence on the part of the family.

Before any work was possible for the family a more desirable flat had to be found. In the new, more cheerful rooms, conditions slowly changed. The cleaning was done by the family under supervision. The father, who heretofore seemed deliberately to hinder the work, finally consented to do his share of the housework. When one of the neighbors gave them a discarded red velvet parlor set with oak trimmings, their joy knew no bounds. The mother no longer pleaded sickness to evade her work. Weekly home demonstrations aroused her interest in baking and cooking. After two months of constant supervision, she made ten loaves of oatmeal bread at one time without fatigue. The children were weighed at the dispensary and each showed a marked improvement and gain.

A Family Finds Itself

Because of the encouraging results, and in order to make sanatorium care unnecessary for the balance of the family, it was decided by the Jewish Aid Society to increase their allowance to meet the advanced cost of living. New kitchen utensils and household supplies were bought. The planning of meals was done by the oldest girl, under supervision at first, and alone after three months. She also kept an expense account with all details. Her meals were well planned and prepared, and it was a joy to know that the entire family was

able to sit at the table at one time. This is just another of the niceties of life which the family were quickly grasping.

It was found that this flat was too small for the needs of the family, and the scurry for a new home was participated in by the entire family. After several months of search the ideal home was found by one of the little boys. It is a sunny, cheerful house with adequate sleeping rooms to warrant a bed for each member. It is situated far back in a deep lot, and has a garden with flowers in the front and an ideal playground in the back; vegetables grow in the lot on the side of the house.

It was in this moving that real results of intensive work were evident. Every piece of furniture worth taking was thoroughly scrubbed and varnished, each member of the family doing a goodly share of the work. They had learned the value of cleanliness which they were carrying out now in actual doing. Everything that was brought into the new home was absolutely clean. The old crex rug which had almost been worn out in service in the old home was cut up into small pieces and bound for use as bedroom rugs. Each member is carrying out the schedule of work as planned with the greatest satisfaction and pride.

Beside the mother's duties which she never neglects, she finds time to do all the sewing for herself and all the children, the clothes being made over from the garments supplied by our store rooms. Today they boast of more clothes than are found in the average middle class home, for the mother has developed the faculty of tasteful combination and the utilization of every scrap to its best advantage. The father who heretofore had never had any real desire to work, is now anxious to give up the stand and secure work where he can make a living wage. In February the oldest girl will finish her two years' business course at high school; the oldest boy will graduate from grammar school at that time and is then to be given advantage of the same commercial course. The physical condition of each member of the family has been closely watched and each shows marked improvement.

The family spirit is one to be envied. Their love for one another has enabled them to rise above the trials that confronted them, and in a few years each member will be self-supporting and a pride to the community.

It is this personal touch with the families which is the greatest asset of the instructive visiting house-keeper. Possibilities are great and through patience and tenacity of purpose a rich harvest of rewards is possible.

A CONSULTATION SERVICE IN TUBERCULOSIS WORK

By D. B. ARMSTRONG, M.D., EXECUTIVE OFFICER, COMMUNITY HEALTH AND TUBERCULOSIS DEMONSTRATION, FRAMINGHAM, MASS.

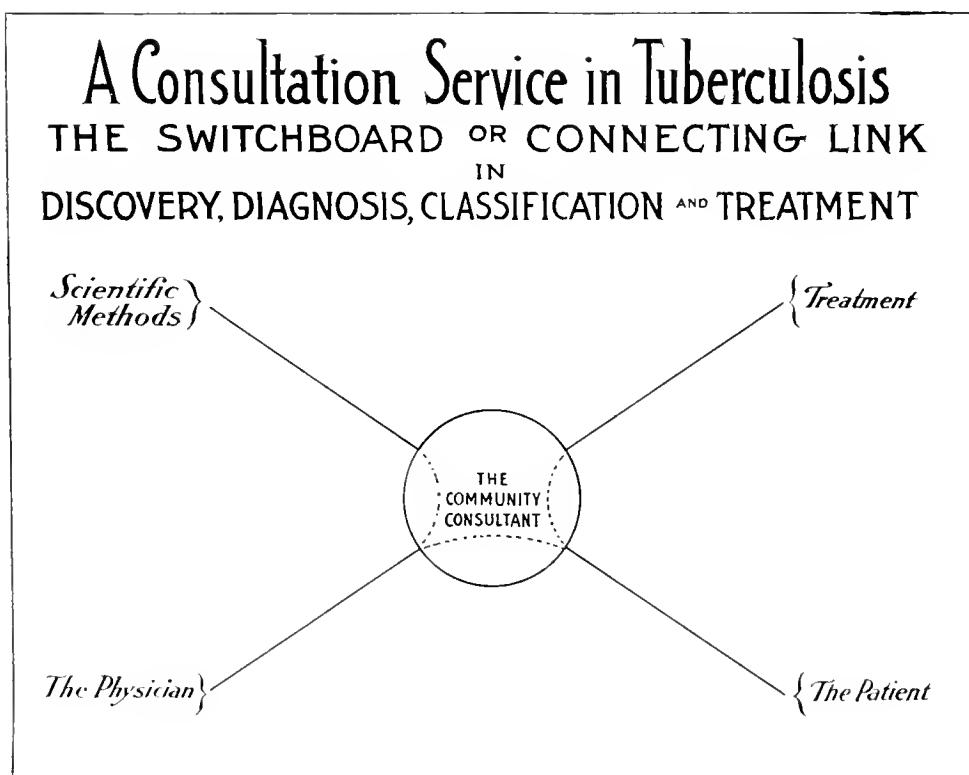

THE experience of the Framingham Community Health and Tuberculosis Demonstration, now under way for approximately two and one-half years, has thrown considerable light upon the essential factors in the tuberculosis program, and has also indicated in a measure the relative degree of importance of the numerous devices which have been employed for meeting the problems of tuberculosis in a typical American community. In a summary fashion, the links that are

V. *Classification*.—Methods, standards, etc.

VI. *Treatment*.—Home and institutional; education, segregation, therapy, prevention; relief, domestic science, social adjustment.

VII. *Subsequent Observation*.—Economic adjustment, employment, constructive hygienic education.

VIII. *Prevention*.—Of infection, of disease; education, sanitation, segregation, personal hygiene.

The Community Consultant serves as a connecting link between the physician and early medical advice for the patient, between the physician and scientific standards of diagnosis and treatment, and between the patient and early adequate treatment.

involved in the complete community chain for handling tuberculosis may perhaps be roughly classified as follows:

I. *Organization*.—Lay and professional organization, interest, coordination, education, public service ideals.

II. *Legislation*.—Sanitary, epidemiological, institutional provision, and appropriations.

III. *Sanitation*.—Cleanliness, respiratory hygiene, etc.

IV. *Disease Detection*.—Reporting, clinics, organized age group work, consultation service.

IX. *Research and Demonstration*.—Study, education, initiation.

It has seemed, in the Framingham experience, that in the development of community tuberculosis programs, the phase of the work most neglected is that of discovery. At the beginning of the Demonstration, there were three known cases for every death, though for some time there had been in the community an excellent clinic and nursing equipment, together with other machinery. This ratio has now been greatly increased, due to the installation of special devices for the discovery of tuberculosis, particularly the

consultation service, which grew out of extensive medical examination work carried on in a volunteer way throughout all sections of the community.

Permanent, Continuous Consultation Service

This preliminary survey served to stir up an unusual amount of interest in tuberculosis among both physicians and laymen. On a basis of general medical examination work there developed a permanent and continuous consultation service, operated on a part-time basis at first, but now demanding full-time service as a result of the increased requirements of the community as expressed through physicians and private citizens. Needless to say, this service requires expert, mature, widely experienced, and tactful personnel.

The services of the full-time physician who serves on the Framingham staff as chief medical examiner and expert consultant were originally offered to the physicians and people of Framingham through special press notices, letters to the medical men, introductions through the medical organizations, etc. Dr. P. C. Bartlett, who has occupied this position on the Framingham staff since the beginning of the consultation work, offers to the local physicians specialist advice on difficult and doubtful cases of pulmonary diseases, the consultations being held either in the doctor's office, in the patient's home, in the dispensary, or health station.

Differentiation in Thoracic Disorders

At the present time, a tendency exists for this service to broaden in scope, and to cover other thoracic conditions such as cardiac disease, general medical complications, etc.

Practically all of the physicians of Framingham now employ this consultation service, which is offered on a pay or free basis, the great majority of the consultations having been given without charge until the present time. The presence of such a consultant in the community also makes possible other lines of approach to the medical aspects of the tuberculosis problem, including the holding of lectures, clinics, demonstrations, etc.

In brief, the advantages of this service may be stated as follows:

Early Detection of Disease

(1) It greatly increases the detection of tuberculosis. While there were 27 known cases on record in Framingham at the beginning of the Demonstration, and while there had been under observation only 40 cases during the year preceding the Demonstration, the number under observation during the first year of the Demonstra-

tion was increased to 185, approximately one-third of these having been discovered through the consultation service. At the present time the total number of cases, excluding the suspicious ones, that have been under observation in Framingham during the Demonstration, is approximately three hundred.

(2) It removes the burden of diagnosis in tuberculosis from the local physician and, consequently, increases the probability of such a diagnosis being made.

(3) It encourages the reporting of disease. During the decade preceding the Demonstration the physicians of Framingham reported an average of thirteen cases a year. This number increased to fifty-nine during the first year of the Demonstration.

(4) It encourages the diagnosis of tuberculosis at an early stage. During the first year of the Demonstration, of the total number of cases reported, 42 per cent were advanced, while during the second year only 16 per cent were advanced.

Post-Graduate Medical Instruction

(5) It offers an opportunity for post-graduate medical instruction, through lectures, clinics, demonstrations, etc.

(6) Through the use of standard methods for the diagnosis, classification, and treatment of tuberculosis, it tends to elevate and standardize medical practice regarding this disease.

(7) The contact between the expert consultant and the local physician means also improved treatment, the consultant being able in numerous cases to advise both the physician and the patient directly regarding therapeutic measures. During the Demonstration thus far about 33 per cent of the active cases have been institutionalized.

(8) It is an increasingly valuable supplement to medical, nursing, and dispensary machinery, and at the present time, in Framingham alone, a town of 17,000 people, the consultant is called upon thirty or forty times a month by a large percentage of the local physicians.

(9) The consultant acts as a connecting link between the physician and the patient, between the patient and treatment, and between the physician and a knowledge of scientific methods.

While the cost of this service for a small community cannot perhaps be justified except on an experimental basis, the extension of the service to cover wider areas and larger populations is anticipated as an outgrowth of the Framingham experience.

Such a consultation service could readily be

offered on a state-wide basis, the work being done in an itinerant fashion, the presence of the consultant being advertised beforehand in various communities, appearing there on a definite schedule, under official or private auspices. Such a program might be initiated on a full or part-time basis, and could probably be readily developed under the auspices of the state department of health, or State Tuberculosis Associations.

Itinerant Consultation Service

At the present time an itinerant consultation service is being operated at the Cape section of Massachusetts under the auspices of the State Department of Health, the State Tuberculosis League, and the Barnstable County Tuberculosis Hospital. The experiment is being tried or is about to be initiated in a number of communities, including Brookline, Mass., Akron, Ohio, Oklahoma City, Okla., East St. Louis, Ill., and in Vermont.

There is, of course, no reason why this form of special advisory service could not eventually be extended to cover other medical needs, and a wider range of diagnostic problems, such as perhaps the obstetric, pediatric and other specialties, together with the problems of general internal medicine.

Function Primarily Diagnostic

The service must be primarily a diagnostic one, cases as discovered being referred to local physicians of the patient's own choosing for treatment.

As indicated in the beginning, the experience in Framingham with the consultation service and with other special measures for the discovery of tuberculosis has led the workers there to feel that, whereas the hospital, the clinic, and the nurse are essential factors in a community tuberculosis program, more attention must be paid to the development of discovering devices. Apparently no community is justified in considering its program adequate if it does not have the advantages of special devices, such as a consultation service for the discovery of tuberculosis.

All over the world today scientific and public health authorities interested in tuberculosis are asking the question: "What is the next step in tuberculosis work?" Various answers are being given to this inquiry. The answer of the Framingham experience is that tuberculosis exists to a greater extent than has hitherto been supposed, and that it must be discovered and brought under treatment before it can be controlled. Consequently the "next step" is the *first step*, namely, the discovery of the disease.

NEW HEADQUARTERS FOR NATIONAL EDUCATION ASSOCIATION

The National Education Association announces that after July 1st, 1920, it will establish national headquarters in the Guggenheim property at 16th and M Streets, Washington, D. C. The association recently came into possession of this property, which is valued at \$98,000. The site is about five blocks distant from the White House and diagonally across the street from the home of the National Geographical Society.

THE QUESTION OF HOSPITAL STANDARDIZATION

Attention was centered upon the practical problem of hospital standardization in both discussions and demonstrations at the October gathering of the American College of Surgeons held in New York City during the last week of October. Studies of the practical application of hospital standardization were made at the Vancouver General Hospital, New York City, the Woman's Hospital, New York City, St. Vincent's Hospital, Los Angeles, and Mount Sinai Hospital, Cleveland, during 1918-19. Accounts of the work done in this direction at the several institutions were given by the superintendents and chief surgeons.

The Rev. Charles B. Moulinier, S.J., president of the Catholic Hospital Association, delivered an address on "Standardization in Catholic Hospitals." His talk was followed by discussion on "The Work of the College in Hospitals" by John D. Bowman, M.D., of the American College of Surgeons. Daily sessions were devoted to operating clinics and demonstrations.

PROBLEM OF HOSPITAL DEFICIT

A deficit of \$3,000,000 in the funds of the non-municipal hospitals in Manhattan was revealed recently in the Fortieth Annual Report of the Fund. A special committee has been appointed by Robert Olyphant, president of the United Hospital Fund, to devise means of lifting this deficit burden from the hospitals. Forty-six hospitals are members of the Fund and during 1918 an aggregate of 1,282,078 free days were included in their medical care. The average daily cost of maintaining non-paying patients, according to the report, has risen from \$2.02 in 1914 to \$3.13 in 1918, an increase of 58 per cent. The estimated cost per patient this year will be \$3.50. Plans for the care of the sick involve adequate hospitalization. That such a deficit can exist shows a serious defect in the present provision for such care.

Institutions affected are:

General Hospitals: Mount Sinai, New York, St. Luke's, Presbyterian, Post-Graduate, Lenox Hill, Roosevelt, Lincoln, Lebanon, Beth Israel, French, Flower, Sydenham, St. Mark's, Knickerbocker, Hahnemann, Volunteer, Polyclinic, and Park.

Special Hospitals: Orthopaedic, Ruptured and Crippled, Deformities, Joint Diseases, New York Eye and Ear Infirmary, Manhattan Eye, Ear, and Throat, Ophthalmic, Knapp Memorial, Skin and Cancer, Memorial, House of Rest, Consumptives, and Neurological Institute.

Women and Children: Lying-In, St. Mary's, Woman's, Nursery and Child's, Sloane Infirmary, Women, Children, Babies', Manhattan Maternity, Misericordia, Jewish Maternity, and Hospital for Women.

Chronic Convalescents: Montefiore Home, Home for Incurables, Isabella Home, House of the Holy Comforter, and St. Andrew's Convalescent.

LAW FOR THE DOCTOR

By LESLIE CHILDS, ATTORNEY AT LAW, INDIANAPOLIS,
INDIANA*

(Is a physician who testifies as a witness in a judicial proceeding disclosing confidential communications liable in damages to his patient?)

In Smith vs. Driscoll *et al.*, 94 Wash. 441, the defendants, Driscoll *et al.*, were licensed and practising physicians and surgeons and had attended the plaintiff, Smith, professionally. Later Smith became a party to a law suit opposing one Leonard, and the defendants were subpoenaed as witnesses, testifying apparently much to Smith's embarrassment. Thereupon Smith brought the action above named, asking for damage for alleged wrongful disclosure of confidential information acquired in their professional capacity.

The exact nature of the alleged confidential disclosure made by the defendants does not appear in the report, and the case turned on a point of law; but the court, in passing upon the issues raised, discussed the question of a physician's liability in situations of this kind in an able manner, saying in part:

" . . . Is a physician who, while testifying as a witness in the course of a judicial proceeding, discloses confidential communications made to him, or professional information acquired by him while prescribing for a patient, liable in damages to the patient for so testifying? . . .

To the ordinary mind it would seem that a physician, while testifying in a court of justice, is in the same situation as any other witness, and his rights and liabilities are to be determined by the same legal standards that are applied to a witness who is not a physician. We can conceive of no possible reason why the protection which the law, . . . places about witnesses generally, should be denied to a particular witness merely because he is a physician. If this immunity is withdrawn in his case surely the situation of the physician as a witness is not an enviable one. If he is interrogated, and required by the court to answer, concerning confidential communications in his professional keeping, and does so, he will be rewarded for his obedience to the law by being mulcted in damages to the aggrieved patient. If, on the other hand, he considers it to be his paramount duty to preserve in its integrity his obligation to his patient and refuses to testify, he will be rewarded for his professional loyalty by being committed to jail. Manifestly, no such barbarous rule would be tolerated by any system of civilized jurisprudence. . . .

"A physician is not permitted to disclose from the witness stand the communications of his patient made in confidence merely because the information would be relevant and pertinent to the issues involved. Before such testimony may be given it also must be admissible in the particular case. The important issue, therefore, in an action against a physician for divulged confidential communications while testifying in the trial of a case, is whether the testimony complained of was admissible in the case in which it was given and was relevant and pertinent to the issues. . . .

"The complaint here does not set forth the nature of the action in which the offending testimony was given, . . . it alleges that the statements complained of were made over the strenuous and timely objection of appellant. This allegation invites the inference that the testimony was given in response to questions and in obedience to the ruling of the court, in which event respondents would not be liable, even though the testimony were both inadmissible and irrelevant."

The court concluded by sustaining a demurrer to the complaint.

It would seem by the holding in this case, which is sustained by the great weight of authority, that before a physician could be held liable in damages to his patient for disclosing confidential communications while testifying

ing as a witness in a judicial proceeding, it would have to be shown that he abused his privileges as a witness in some manner. Witnesses are granted a certain amount of immunity from civil liability for statements made in court, and, so long as the testimony given is relevant and pertinent to the cause, there can attach no civil liability; that the physician enjoys this immunity in common with other witnesses cannot be doubted.

Whether a given interrogatory is admissible, relevant, and pertinent is a question for the court to decide when presented. If then, the physician witness is of the opinion that to answer might involve him in an after dispute, he may avail himself of his privilege as a witness and decline to answer until ordered to do so by the court.

If the court decides that the question is proper and directs him to answer, he may do so without fear of incurring after civil liability regardless of how offending his testimony may be to a third party, this assuming, of course, that in his reply he stays within the record answering in good faith and to the point.

New Chairman for National Research Council

Dr. Henry A. Christian, Hersey Professor of the theory and practice of physic at Harvard University, has assumed in Washington, for the academic year 1919-20, the position of chairman of the Division of Medical Sciences of the National Research Council. Doctor Christian has been physician in chief of the Peter Bent Brigham Hospital, Boston, since 1911, and was dean of the faculty of medicine of the medical school of Harvard University from 1908 to 1912. He is a well known and active member of various national associations of medical men and of the American Academy of Arts and Sciences.

OCCUPATIONAL THERAPY

During the war, the Department of Nursing and Health of Teachers College, Columbia University, gave short courses to meet the emergency demand of the army for reconstruction aides in occupational therapy. Montefiore Hospital furnished the practice field for the Teachers College students and two hundred received training there during 1918-19. As a result of this combination of theory, technical instruction, and practice teaching, the board of directors of Montefiore is offering six scholarships of \$350 each for work at Teachers College next year in occupational therapy.

The successful results of using occupation for its therapeutic and moral value in army hospitals has awakened wide interest and given an impetus to the development of such work in civil hospitals. It might be expected that a large number of the aides who were inducted into the army hospitals during the war would be available for this purpose, but a survey shows that a considerable proportion of them will return to former occupations or that they entered the work as a war service and do not wish to continue in professional life. Moreover, since many entered the military service on the emergency call, without the training necessary for qualified workers, even the experience they have gained in hospitals will not make up for their lack of technical knowledge and wider vision which is required of those who undertake to direct the work, and so there is a dearth of qualified supervisors and directors for this field.

A committee of the National Society for the Promotion of Occupational Therapy has formulated a standard course of training for occupational therapy teachers, and a course which in the main coincides with this will be

*The seventh of a series of articles on "Law for the Doctor," written for MODERN MEDICINE by Leslie Childs.

offered at Teachers College and at Milwaukee-Downer College next fall. This field of work opens up a new profession for women, for it is fast becoming distinct from that of nursing, and it is one which has the double interest of dealing with the production of hand work, which appeals to the craftsman, and with human problems, which appeal to the nurse and social worker.—*The Survey*.

AMERICAN CHILD HYGIENE ASSOCIATION

The Tenth Annual Meeting of the American Child Hygiene Association will be held at Asheville, N. C., November 11-13. This meeting immediately follows the session of the Southern Medical Association which will be held at Asheville November 10-13. Their program shows a number of interesting papers to be presented by authoritative speakers and without doubt the aims of the Hygiene Association will be furthered by the joint meetings and discussions which are arranged by the State Medical Society.

The chief papers on the program follow:

The Maternity Problem in New York City with Special Reference to the Social Aspects, Dr. Ralph W. Lobenstein, New York. Discussion opened by Miss Anne Stevens, New York.

Prenatal Care in Massachusetts, Dr. Robert L. DeNormandie, Boston. Discussion opened by Dr. Merrill E. Champion, Director, Division of Hygiene, State Department of Health, Boston.

Maternal Benefits and Its Bearings on Prenatal Care, Dr. Merrill E. Champion. Discussion opened by Dr. Fritz B. Talbot, Boston.

Report of Breast Feeding Bureaus at Minneapolis, Dr. J. P. Sedgwick, Minneapolis. Discussion opened by Dr. Richard M. Smith, Boston.

How May the General Practitioner Be Interested in the Modern Socio-Medical Program for Infancy? Dr. Richard A. Bolt, Oakland, Cal. Discussion opened by Dr. Joseph S. Wall, Washington, D. C.

Help in the Home for the Mother with a Young Baby, Dr. Helen MacMurphy, Toronto. Discussion opened by Dr. Mary Sherwood, Baltimore.

An Infant Hygiene Campaign in the Second Century, Dr. John Foote, Washington.

General Outline of Welfare Work for the Child from 2-6. From the Viewpoint of the City, Miss Sara B. Place, Supt. Infant Welfare Society, Chicago. From the Viewpoint of the Rural Community, Mrs. Virginia Knox Kimble, State Supervisor of Nurses, Topeka.

Statement of the 1919-1920 Program of the National Organization for Public Health Nursing, Miss Zoe LaForge, Children's Bureau, Chicago.

The Work of the University Extension Service in the P. H. S., Washington, D. C.

Prevention of Infant Mortality; Mrs. Louis Selbert, Specialist in Home Nursing and Health, Agricultural Extension Service, University of Missouri, Columbia.

What England and Scotland Are Doing for Children of Pre-School Age, Dr. William Palmer Lucas, San Francisco, Chief of the Children's Bureau of the American Red Cross in France; Miss Ellen C. Babbitt, Washington, D. C.

Observations on the Supervision of the Pre-School Age in the Large City, Dr. Walter H. O. Hoffmann, Chicago.

Correctable Defects Under Six Years of Age, Dr. Adelaide Brown, San Francisco.

Psychiatry, with Special Reference to Children of School Age, P. A. Surgeon Walter L. Treadway, U. S.

"Alias Hygiene," Dr. Thomas Storey, Interdepartment Social Hygiene Board, Washington, D. C.

Oral Hygiene, Maj. Harry B. Butler, U.S.A., Washington, D. C.

Rural, Dental, and Surgical Clinics, Dr. George M. Cooper, Director, Bureau Medical Inspection of Schools, North Carolina State Board of Health, Raleigh. Discussion opened by Dr. Taliaferro Clark, U. S. Public Health Service, Washington, D. C.; Dr. Julius C. Levy, State Board of Health, Newark, N. J.

Opportunities of the Rural Public Health Nurse for Developing Child Hygiene, Mrs. Ruth A. Dodd, South

Carolina State Board of Health, Columbia. Discussion opened by Mrs. Kate Brew Vaughn, North Carolina State Board of Health, Columbia; Dr. A. T. McCormack, Secretary, State Board of Health, Bowling Green, Ky.

The Minnesota Rural Clinic, Dr. E. J. Huenevens, Minneapolis. Discussion opened by Dr. Richard M. Smith, Boston; Dr. Anna E. Rude, Children's Bureau, Washington, D. C.; Dr. J. P. Sedgwick, Minneapolis; Dr. N. C. Pearce, Minneapolis.

MISSISSIPPI VALLEY CONFERENCE

The Seventh Annual Session of the Mississippi Valley Conference on Tuberculosis was held at Des Moines, Ia., on September 22 to 24, 1919, under the presidency of Sherman C. Kingsley of Cleveland, Ohio. Attendants from twelve states comprised the conference and more than five hundred workers were present. This organization urged the necessity for uniform legislation for the control of tuberculosis; for more complete cooperation of the governmental and extra governmental health agencies.

Much interest was aroused by Julia Lathrop, chief of the Federal Children's Bureau, Washington, D. C., by her discussion of the subject, "Tuberculosis, An Evidence of the Need for Child Welfare Standards," and also by Owen R. Lovejoy, president of the National Conference on Social work, New York City, on "Prevention."

Two subjects which were given special and detailed prominence throughout the session were "Occupational Therapy in the Treatment of Tuberculosis Patients," and "The Eradication of Tuberculosis Through Our Efforts With the Child, Plus the All-Important Education of the Public," presented, respectively, by Mr. Kidner, of the National Tuberculosis Association, and Miss Beatrice E. Lindberg, who represented the Advisory Commission of Minnesota.

Various "lessons from the war" were presented by different speakers, among whom were Dr. George T. Palmer, of Illinois; Major W. H. Watterson, M.D., Federal Board of Vocational Education, Washington, D. C.; Mr. Kidner, of New York; and Dr. Walter J. Marcley, of Minneapolis, Minn.

Another topic which was brought into prominence before the conference of the Mississippi Valley Sanatorium Association was that of nursing problems, suggested by a paper of that title by Dr. R. L. Williams, of the Wisconsin State Sanatorium, who advocated correspondence courses for the training of tuberculosis nurses in the smaller sanatoriums not capable of maintaining training schools. His idea was well received. "The Standardization of Sanatoriums," a report of the committee appointed at the 1918 conference, consisting of Dr. George T. Palmer, of Illinois; Dr. E. R. Vander Slice, of Michigan; and Dr. Robinson Bosworth, Chairman, St. Paul, Minn.

The officers of the Conference were: President, Sherman C. Kingsley, Cleveland; vice-president, W. J. Pettit, M.D., Ottawa, Ill.; and secretary-treasurer, Ralph J. Reed, Des Moines, Iowa.

Officers elected for next year are: Dr. John H. Peck, Des Moines, president; Dr. W. McN. Miller, St. Louis, vice-president; and Dr. A. T. Laird, Duluth, secretary-treasurer. Mr. Kingsley was elected to the executive council and Mr. Nels A. Nelson, Cincinnati, and Miss Charlotte Ludwig, Cleveland, were elected to the Advisory Council to represent Ohio.

The 1919 officers for the Mississippi Valley Sanatorium Association were: President, Dr. H. V. Scarborough, superintendent of the State Sanatorium, Oakdale, Iowa; secretary-treasurer, Dr. E. B. Pierce, superintendent of the Michigan State Sanatorium, Howell, Mich.

The 1920 officers of the Mississippi Valley Sanatorium Association are: President, Dr. Robinson Bosworth, St. Paul, Minn.; vice-president, Dr. G. L. Bellis, Muirdale Sanatorium, Milwaukee, Wis.; and secretary-treasurer, Dr. E. B. Pierce, State Sanatorium, Howell, Mich.

The 1920 conference will be held in Duluth, Minn.

DEFECTS IN STATISTICS

A strong argument against the indifference and often actively antagonistic attitude of physicians toward statistical methods and the onus of their duties in regard to the reports necessary in compiling vital statistics is found in an attempt to discover from our statistics the total loss of young life which occurs before birth, at birth, and during the first year after birth. In a paper published by Ballantyne in "Maternal and Child Welfare" in October, 1919, are suggested several new rates in studying infant mortality. The deductions in his paper are drawn from a study of Edinburg birth rates, infantile death rates, and neonatal death rates for the years 1911 to 1917 inclusive.

His summary of the factors involved in infant mortality is: (1) The antenatal factor, determined by placenta; (2) the intranatal factor, injuries in child birth; (3) the postnatal factor, the germ-laden environment; (4) a complexity of causes. The relative importance of these factors in infant mortality are important subjects of study but they must be mastered if they are to be understood and combated.

FORBIDS PHYSICIANS TO SUPPLY NARCOTICS TO DRUG ADDICTS

A recent decision of the Supreme Court of Minnesota is to the effect that the Anti-Narcotic Law of Minnesota prohibits the furnishing of habit forming drugs to addicts by physicians. The test case, as given in the *Public Health Reports*, was that of a physician convicted in the lower court of selling morphine to an habitual user of the drug. The defendant admitted furnishing the drug, but claimed that he furnished it in an attempt to cure the drug habit and that under the law he could both prescribe and furnish the drug to addicts for such purpose. The court held that the language of the Act was plain that a physician may prescribe in good faith any substances he deems necessary for the treatment of a patient, but that he must not furnish the drugs.

TRAINING FOR TUBERCULOUS SOLDIERS

Discharged soldiers suffering from tuberculosis are placed in training by the Federal Board for Vocational Education under the same conditions as are men with other handicaps—some with support during training, others without support, and a few while they are still in the army hospitals.

Before a tuberculosis soldier is eligible for training, the medical officer must pronounce his case apparently cured or arrested. Quiescent cases of pulmonary tuberculosis having had negative sputum for a period of at least two months must be specially recommended by the district medical officer and during the course they must remain under expert medical supervision.

If the disease is still active, and the patient is receiving hospital treatment, training will be given only upon the endorsement of the hospital authorities who shall also approve the kind of course provided. Men whose cases are active, but who refuse to take hospital treatment are considered ineligible at the time, but their cases will be

reeconsidered should they be physically able to undertake the work later.

ARKANSAS LEGISLATES FOR HEALTH

Among legislative measures pertaining to public welfare passed in Arkansas in 1919 is a bill to establish the Arkansas State Farm for delinquent women. The new law provided for lands and proper housing, and corrective measures. Provision is made for adequate medical attention.

Two bills were passed affecting Sebastian and Phillip counties which, although local in character, are significant as they indicate the general trend of sentiment everywhere toward full-time health officers.

The Dalton Drainage Bill was vetoed, but the discussion of this matter evidences the demand by the people for general measures to control malaria, the principal object of this bill being malarial control.

A PROBLEM OF RECONSTRUCTION

"With regard to the significance of the word 'reconstruction,' I would state that medicine has always progressed by evolution rather than by revolution," writes George Blumer, M.D., in *American Medicine*, who says further:

"Of the particular aspects of the reconstruction of the medical profession which are to be considered it has seemed to me that those which are of the greatest interest to the general public are the ones which concern the contact between it and the profession. Of the changes which should be brought about in the relationship of the medical profession to the public mention may be made of the following:

"The medical profession is at present mainly organized with a view to the cure of disease rather than the prevention of disease. It is highly desirable that the emphasis should be changed and that prevention should be not only recognized as the desirable ideal but that more active measures be taken to put it into effect.

"Aside from communal methods of prevention, such as good water supplies, good sewage, proper housing conditions, etc., which must not only be persisted in but must be made universal, the hope of the future lies in individual hygiene. The basic principle underlying the enforcement of individual hygiene is the periodic health examination, and this must begin with the examination of the expectant mother and must continue throughout the life of the individual from infancy to old age. Combined with it there must be obligatory instruction of all children during the school age in the fundamental laws of health, and to this must be added obligatory physical training.

"In order to carry out this program it will be necessary to greatly increase the number of community physicians and at the same time to greatly increase the number of their co-workers, the public health nurses. It is doubtful whether a wholesale change in the methods of medical practice such as has been suggested can be brought about in the first place without great expense. Whether this expense should be met by an increase in direct taxation or whether it could better be met by the extension of the principles of health insurance is a question which can perhaps be more satisfactorily decided by the economists than by the physicians.

"The successful diagnosis and cure of the more obscure diseases have become so complicated and expensive that ways must be found of permitting the average citizen to avail himself of modern methods at reasonable cost."

THE MONTH IN MEDICINE

Survey of Current Medical Literature with Editorial Comment

WALTER W. HAMBURGER, M. D., Editor

THE VISITING HOUSEKEEPER

ON another page of this issue will be found a report of the pioneer visiting housekeeping carried on by the Jewish Aid Society of Chicago. To us Miss Markman's article is of particular significance; besides carrying a message, it gives a point of view. There has been a growing tendency in social work to maintain the wholeness of the home, but it has been often exceedingly difficult to accomplish this purpose.

Institutions in allied social endeavor are apt to exaggerate the importance of their work, or at least neglect opportunities not definitely connected with their specific problem. A tuberculous patient at a sanatorium is the possessor of râles and tubercle bacilli rather than the potential supporter of his family. Any effort, then, which aims to maintain intact the family relationship should receive careful attention.

In connection with the problem of the proper feeding of the poorer classes, it would seem to us that most social endeavor has overshot the mark and missed the main point at issue. Dietetics is a science whose greatest value lies in its proper individualization and application. Physicians have learned that the treatment of diabetes to be successful must be carried on with the intelligent cooperation of a good cook. All the hospital investigations are of no avail unless the work is carried on from the patient's point of view.

Expressed from a little different angle, this means that a diet is not prescribed in the abstract suitable for an abstract disease; but that the deficiencies or errors of the individual patient's diet are recognized and corrected. It is not sufficient to tell a patient with nephritis to adhere to a "salt-free, non-nitrogenous diet"; it is necessary to discover in the patient's diet articles of food which are not possible under this régime and to substitute other articles which are indicated.

So in all community problems connected with diet, teaching must be from the point of view of

the individuals or groups of individuals whom we are attempting to instruct. A dietitian working in a Jewish community which will not break the laws of Kosher feeding has an entirely different problem from the dietitian in, for example, a Polish Catholic community. It would be of little avail to lecture to these people on an ideal feeding schedule. It has been demonstrated more than once, and Miss Markman's paper again demonstrates it, that to be successful, dietary instruction must be given in the home. Ignorance of food values, of the economy of buying by calories per ten cents can easily enough be overcome if the instructing dietitian knows exactly what the family is eating.

And in this method of instruction every member of the household is a potential unit for the furtherance of the family health and the maintenance of the family integrity. The home is made the school, and other lessons in proper living are taught right in the home. An active cooperation rather than a passive interest is obtained. Likewise, potential instructors for the surrounding community and future leaders in the community are being developed.

DIETARY STUDIES IN THE ARMY

SHORTLY after the United States entered the war a group of clinicians, chemists, and other men interested in the question of scientific dietetics was called together to form "the Section of Food and Nutrition, Division of Sanitation, Medical Department, United States Army." Men who made up this group were all specially trained in the work they had to do and the Division undertook a broad, comprehensive survey of the whole question of feeding our soldiers at home and in the field in France. The *American Journal of Physiology* for September, 1919, contains a series of reports by various members of the Division based on these studies. It has rarely been possible to combine the opportunity for study of the dietary question on such a large

scale with the facilities and the men necessary to complete such a study. As might be expected, the results of these investigations must be of great practical value for the solution of many problems connected with all phases of the diet question. In this review only the salient features brought out by the studies will be emphasized.

R. J. Anderson writes on the "Practicability of Feeding a Scientifically Balanced Ration in Army Camps." This work can be transcribed to read, the practicability of feeding a scientifically balanced ration to any large group of individuals. As Anderson says, the most important problems are those concerned with (1) the available food supplies; (2) the matter of storage and prevention of spoilage; and, (3) cooking. The relative proportion of protein, fat, and carbohydrate; the acid and basic elements; the vitamins; and the roughage or indigestible residue are the important elements in the question of selection. Emphasis is laid on the fact, often neglected, that in considering what constitutes a balanced diet it is self-evident that men do not live on calories alone. Palatability and digestibility, as well as variety, are essentials. But the method at first employed in the army of furnishing a so-called garrison ration, which formed merely the basis upon which the cash value of the ration allowance was calculated, permitted individual organizations to spend money for food other than that furnished by the garrison ration; in other words, if an allowance of fifty cents a day per man was the basis of the garrison ration and only twenty-five cents worth of food per man was obtained in the garrison proper, the rest of the money could be spent by the mess sergeant for food purchased outside. This method allowed a wide range of individual judgment in the purchase of food and made the study of the different messes for that reason particularly interesting. Even after a mess force had had several months' experience it was not unusual to find the average food consumption varying by 1,000 or 1,500 calories per man per day in adjacent companies in the same regiment. "Good cooks and high food consumption appeared to stand in direct relation."

The development of the schools for cooks and bakers helped to improve matters somewhat in the long run; however, most of their training seemed to have been along the lines of mess accounting rather than along the lines of scientific diet. Anderson is of the opinion that there is urgent need for continuing such schools, but believes that it will be necessary to give more thorough instruction in the art of cooking than was generally given in the schools during the past

year. Of particular interest for hospitals and other organizations feeding large numbers of men is Anderson's suggestion that tentative menus be made out for definite periods, as for ten days in advance; that these menus might well aim to provide an average of 3,600 net calories per day per man doing moderately hard work.

The Division of Food and Nutrition proposed a diet furnishing a balance of calories as follows: protein $12\frac{1}{2}$ per cent, fat 25 per cent, carbohydrate $62\frac{1}{2}$ per cent. However, as will be shown subsequently, this is not the diet which was actually used by most organizations during the war. The fat content of this diet is lower by approximately 6 per cent than that actually used by the messes, and on the officers' table it was found that fat supplied 40 per cent or more of the total calories.

Anderson believes that in the interest of good nutrition a uniform menu should be adopted for a whole camp but only under the direction of competent authority. The menu made out for ten to fifteen days in advance would then give the supply officer an opportunity to secure the necessary raw material and, since the menus would specify the amount in pounds of the different foodstuffs actually to be used, a diet of any desired composition or balance could be provided.

Some of the results of the dietary studies made by survey parties of the section showed nutritional errors which could easily have been prevented under the type of supervision suggested by Anderson. For instance, in two adjoining organizations in the same camp at the same time of the year two following menus occurred:

	Grams		Calories per cent	
	1	2	1	2
Protein	85	121	12	13
Fat	59	145	20	33
Carbohydrate	472	540	68	54
Total calories	2,830	4,100		

Both of the messes were well managed and the mess sergeants were above average ability. In mess No. 2 the men were receiving more food than they needed; in mess No. 1 the men were decidedly underfed, but the men in both organizations felt they were being well fed. In mess No. 1 liberal quantities of cabbage, sauerkraut, onions, and potatoes were used—and the stomachs were filled. It is well to emphasize this contrast because it is such a common mistake in daily life. Only too often quantities are purchased instead of calories.

Murlin and Hildebrandt discuss "Average Food Consumption in the Training Camps of the United States Army," and their statistics will unquestionably form the basis for subsequent

studies on the American ration. In an average of 427 messes studied the figures were as follows:

Nutrients	Supplied	Wasted	Consumed	Wasted per cent	Per man per day
Protein, grams	131	9	122	7	Supplied cost, cts. 41.06
Fat, grams	134	11	123	8	Waste cost, cts... 3.20
Carbohydrate, grams...	516	31	485	6	Total waste, lb... 0.80
Fuel value, calories....	3,899	266	3,633	7	Edible waste, lb... 0.38

Analyzing this chart, it was found that on the basis of an average weight of 146½ pounds the average food consumption of the American soldier in training is 24.6 calories per pound body weight, or 52.1 calories per kilogram.

When studying the variations in food consumption for the entire 427 messes, it was found that this ranged from 2,100 to 5,700 calories, with the mean of 3,600 to 3,700 calories. For all practical purposes it can be stated that the range of food consumption, however, lies between 3,000 and 4,500 calories, with the average very close to the mean of these two extremes.

An effort to study food consumption by the various organizations showed that the average figures of the recruit organizations was some 200 calories less than the average total consumption. The effect of seasonal food consumption is clearly seen in the gradual increase from November to March, followed by a sharp decline which continued throughout the summer. However, this increase during the winter months is probably not altogether due to atmospheric conditions, but in part to the stimulus by winter weather to muscular work. The authors use the words "muscular willingness" to indicate the indirect effect of cool weather. They believe that there are many gratuitous muscular motions in the performance of any given piece of work when the temperature and humidity are low and the barometer is high. The conclusion of the study of seasonal variation shows that the average soldier weighing 146 pounds will consume not more than 400 calories extra food.

The effect of the length of time in camp on the food consumption is likewise clearly indicated from these studies. A recruit company at Camp Pike during July and August, 1918, began to consume 2,700 calories per man per day, and ate more every week until by the end of the fifth week the average of all messes was about 3,600 calories. An interesting explanation is offered for these variations of food consumption. The first two weeks in camp cover the period of inoculation for typhoid and paratyphoid. This, together with the strangeness of the surroundings, particularly of the mess, menus, cookery, style of service, and lack of digestive capacity, serves to

keep down food consumption and is responsible for the noticeable loss of weight in the first week. Incidentally, the weight was promptly recovered by the end of the third week.

Extra food that was consumed in the canteens, and in some instances in the restaurants and candy shops of the district surrounding the camp, was difficult to estimate; but one study made at Camp McClellan shows an expenditure per man per day of 21.9 cents for food, distributed as follows:

Article of Food	Cost	Percentage
Candy	\$0.0617	28%
Drinks0505	23%
Cakes, cookies0658	30%
Fruit0106	5%
Ice cream02	9%
Sandwiches, etc.0106	5%

Three very good reasons are given for the soldier buying food at the canteen, or, for that matter, why members of any organization fed on a schedule always demand extras: (1) as a pastime and for sociability; (2) to secure sweets that take the place of alcohol; (3) because the desire for sugar, physiological or habitual, is not met by the army ration. In terms of calories the average net consumption of the messes surveyed at Camp McClellan was 3,827 calories per man per day, to which must be added 633 calories eaten at the canteen. This gives a surprisingly high total of 4,460 calories.

Comparing food consumption in the army with other occupations, it is noted that the 4,000 calories of the average soldier is slightly under the consumption of stone masons doing heavy labor and slightly exceeds that of farmers, machinists, and carpenters. The distribution of nutrients in the army diet showed that of the total calories 14 per cent were derived from protein, 31 per cent from fat, and 55 per cent from carbohydrate. The interesting feature of this distribution of calories is the comparatively low protein content and the comparatively high fat content as compared, for instance, to the standard dietary of Voit. It is, however, considerably higher in protein than the Canadian ration, somewhat higher than the British and Italian, and less than the French. The total caloric value of the diet, however, is higher than that of any of the countries just mentioned.

Recognizing that one of the most important factors of a diet for maintenance of morale is variety, Murlin and Hildebrandt studied the number of articles furnished per week. It was found the average number of articles used per mess per week was about fifty-five. For organizations on the march, however, the average number was sixteen. An average American family has thirty-

nine different articles of food which enter into the weekly food inventory. The authors conclude "that army feeding, so far at least as variety is concerned, compares very favorably with household feeding."

Howe, Mason and Dinsmore discuss the "Variations in Strength and in the Consumption of Food by Recruits and Seasoned Troops," and Blatherwick has a very interesting discussion on the "Acid-Base Balance of Army Rations." The question of acid-base balance is one comparatively new and one concerning which any information will be of value. It is known that acid-forming foods lead to the formation of acid urines and base-forming foods cause the excretion of less acid or alkaline urine. Although the exact relationships of the acid- and base-forming elements of diet are not settled, the consensus of opinion is in favor of an approximate balance.

The garrison ration for the army, when completely eaten, showed an excess of acid-forming elements corresponding to about 44 cc. N 1 solution per day. The purchase by the mess sergeant of other substances in the open market seems to introduce larger amounts of the base-forming elements. The studies made by Blatherwick at the various camps show that some of the diets are strongly acid-forming, some are neutral, and others contain an excess of base. The hospital diets were almost uniformly base-forming, probably due to the more extensive use of milk, fruits, and vegetables.

One phase of this question touched upon by Blatherwick is the possibility that the continued use of acid-forming diets might lead to a greater susceptibility to diseases of the less infectious type. It was very difficult to answer this question, but one study at Camp Wheeler seemed to show a relationship between amounts of meat, acid-forming, supplied and the duration of the disease. We quote the last paragraph: "The results obtained at Camp Wheeler are suggestive of a possibility that an acid-forming diet consumed for long periods of time may lead to a greater susceptibility to disease of the less infectious type. Those who have control of the feeding of the large numbers of persons in our public institutions might well undertake an investigation of this problem. In such institutions the necessary control of the diet and of the other factors should be more easily obtainable than in the army."

Prescott discusses the use of dried vegetables by the army. We wonder how many people know that "during the Boer War dried soup vegetables which had been stored in paraffined barrels for over fifteen years, were used by the troops, thus

indicating the keeping quality of these dehydrated products." Prescott examined many of the products in use by the army and discusses them from the standpoint of cost, saving of space and transportation, and in storage, keeping quality, wider range of vegetable foods, and generally improved diet through increase in roughage, alkaline salts, and variety of combinations possible. The rush of getting the large amounts of such material ready in a hurry has not made for ideal results. Approximately 40,000 tons of dehydrated vegetables, principally potatoes, also carrots, turnips, onions, and large quantities of soup mixture have been shipped for our forces overseas during the past two years. Officers of the Quartermaster Corps are quoted as responsible for the statement that these dried foods resulted in great saving in labor, were found fairly acceptable to the men, satisfactory to the subsistence officers and cooks, and in general an excellent and easily handled form of vegetable food. From the standpoint of general use in large amounts, chemical analysis, fuel value, and maintenance of bodily strength, properly dehydrated products are practically equal to fresh materials. The question of antiscorbutic and growth-promoting properties of dehydrated vegetables is probably not completely settled. During the siege of Kut it was reported that some of the British forces were afflicted with scurvy as the result of constant and exclusive use of dried foods. Guinea pig investigation has shown that a diet composed entirely of dried vegetables of non-acid character is greatly weakened in antiscorbutics or has lost them altogether, while with dried fruits of acid character, such as tomatoes, oranges, and lemons, scurvy does not result even after long continued feeding. Prescott is of the opinion that dried vegetables and fruits, when the method is perfected, will have a decided and definite place in the dietetics of the army, especially in winter and in places where an abundant and cheap supply of fresh materials cannot be obtained.

Hoskins has collected the reports of several survey parties on the American military hospital dietaries. In the hospital, food is a question of therapeutics, and in this respect handling of a hospital food problem is different from the work in the camps. Hoskins conceives that there are eight classes of individuals to be dealt with in the army hospital:

- (1) Normal men at fairly active work, needing approximately 3,600 calories daily.
- (2) Normal men at sedentary work, needing approximately 3,200 calories each.
- (3) Convalescent patients, metabolically normal, approximately 2,600 calories each.

(4) Bed patients, metabolically normal, approximating 2,000 calories.

(5) Subacute febrile patients, those with empyema especially, needing high caloric and high protein feeding. Experience at Camp Lee has shown that empyema results in a constant drain on the body nitrogen which should be compensated in the diet.

(6) A class of patients not sufficiently ill to receive special diets, but whose convalescence could be hastened by careful attention to their dietary. Such patients, for instance, as pneumonia convalescents should have meals planned especially for attractiveness and high caloric content.

(7) Constipated patients, requiring laxative components in their meals. "The routine use of cathartics in the wards is a reflection on the dietitians."

(8) A special group of diseases, including nephritis, diabetes, cardiovascular disorders, gastro-intestinal, and acute surgical cases, which

must be treated by special dietary therapeutics.

So-called light diets in two hospitals were studied. The caloric consumption in one was 2,535 and in the other 1,916. The food proportions were very similar to those found in the average army mess. The sick officers' ward has furnished interesting data. The caloric consumption was 3,570, the fat consumption 39 per cent, and the evidence is clear that these patients got approximately what they wanted to eat rather than what was good for them. In the nurses' mess the caloric consumption amounted to only 2,859, while an officers' mess showed a consumption of 3,685. Studies of the relative expenditure for separate items show that the hospital expenditure for meat and condensed milk was less and that for eggs, fresh milk, butter, and fresh fruits materially higher than that of the army at large.

In conclusion, the reviewer wishes to express the hope that all of the work of the Division of Food and Nutrition will be collected and put in available form for wide distribution.

COLLECTIVE ABSTRACT RECENT WORK IN MALARIA CONTROL

BY H. O. NOLAN, M.D., LL.D., F.I.C., NEW YORK

IN September, 1897, the author landed at the pretty French town of Ismailia on the Suez Canal. He then made, for the first time, the acquaintance of the mosquito net and heard the song of myriad mosquitos, for they came, not in single spies, but in battalions.

A few years later he again spent a night at Ismailia. This time he was able to sleep in comfort without a net. Not a mosquito was to be seen, and the town, formerly a notorious center of malaria, was entirely free from that scourge.

Malaria Control Instituted

The beneficent change had been wrought by Ronald Ross in a very short time. It was the first large scale and thorough work of this kind that had, up to that time, been undertaken. Since then much equally successful work has been done in stamping out malaria by the methods elaborated by Ross, the most familiar of which to our readers, being that done in the Panama Canal Zone.

Experience has shown that these happy results can be repeated in all urban districts and in most rural districts. So far as the practical elimination of malaria is concerned, success may

safely be reckoned on even in rural districts presenting the most difficult features, notwithstanding that, in some of these, measures for the complete destruction of the anopheline mosquitos may offer difficulties of an economic order which may be relatively insuperable. In such cases the eradication of malaria is effected by the protection of the inhabitants and by sterilization of plasmodium carriers.

No New Methods of Attack

Owing to the maintenance of large forces in Macedonia and other malarial regions, the individual prophylaxis against and the treatment of malaria were subjected to the same searching re-examination as was accorded to other medical problems which acquired acute importance during the war. On the whole one may say that, while nothing new emerged, there was satisfactory confirmation of established practice. No other specific and no better prophylactic than quinin was discovered.

On the civil side, also, the recent publications on the subject of malaria and malaria control are marked by no striking novelty. They are none the less valuable as affording relatively

exact data on the problems of malaria and especially of malaria control.

In this group the most important papers are those from the pen of Bass, relating to the work undertaken jointly by the International Health Board and the Mississippi State Board of Health. These deal with investigations and operations conducted in the heart of the malaria district of the Mississippi. The various methods of malaria control have been tried out under conditions of scientific exactitude in urban and rural districts in that region after adequate surveys. The results will be summarized later under the appropriate heads.

From the practical point of view, the embarrassment caused by the conflict of agricultural exigencies and the desiderata of mosquito control is nowhere more acutely felt than in malarial districts where rice is grown. The papers of Geiger and his collaborators are therefore highly welcome, in that they deal with the experimental investigation of this problem, and with its successful solution.

Gray writes with precision on the cost of malaria, that is, the economic loss, in a district of California and furnishes us with cogent arguments, expressed in dollars and cents, for malaria extirpation.

The methods available for malaria control are: (1) sterilization of plasmodium carriers; (2) prophylactic quininization; (3) prevention of access by mosquitos to human beings, chiefly by screening; (4) anti-mosquito minor measures, or covering breeding places; destruction of larvae, etc.; and (5) major drainage.

We will deal with the first four as they were applied in the work reported by Bass.

Sterilization of Plasmodium Carriers

Although the prominence now given to the sterilization of carriers as a factor in malaria control is somewhat of an innovation, it is a natural corollary to our knowledge of the etiology and to the normal practice in other diseases.

In an investigation made in 1918, covering a population of 3,815 persons in Sunflower County, Bass found that from 50 to 70 per cent of malaria cases are relapses and not new infections. This fact, which also follows from an examination of other statistics, is enough to justify, on clinical and epidemiologic grounds, an attempt to sterilize all carriers.

Estimates based on three years' work in the Mississippi delta lead to the conclusion that this method alone, if adequately pushed, would reduce malaria by 90 per cent in ten years.

In 1916 practically the whole population of

Bolivar County (31,459) was subjected to a survey for malarial infection. Those infected were treated for disinfection by quinin.

Re-examination after four weeks of treatment showed that 60 per cent of the cases had been sterilized. After eight weeks of treatment, 90 per cent were found free from plasmodia. In the latter series were included some relapses.

Method of Procedure

The method consisted of the administration of ten grains of quinin sulphate each evening, just before retiring. The dose for children was one-twentieth of the adult dose for each year of life.

Re-examination of 9,818 persons showed that a larger percentage of adults was disinfected than of children. Readjustment of the dosage was therefore needed. From the data collected Bass established the following figures:

PROPORTIONATE DOSE OF QUININ REQUIRED TO PRODUCE EQUAL RESULTS IN CHILDREN AND ADULTS

Age.	Proportion of adult dose	Dose when adult dose is 10 gr.
Under 1 year.....	0.05	0.05 gr.
1 year	0.1	1 gr.
2 years	0.2	2 gr.
3 and 4 years.....	0.3	3 gr.
5, 6, and 7 years.....	0.4	4 gr.
8, 9, and 10 years.....	0.6	6 gr.
11, 12, 13, and 14 years.....	0.8	8 gr.
15 years and over.....	1.0	10 gr.

Principles in Wholesale Measures

The principles which must govern action in attempting wholesale disinfection in this way are stated as: (1) treatment which will destroy every parasite; (2) avoidance of inconveniences and discomfort; and (3) economy.

As quinin is slowly absorbed and slowly eliminated, doses at short intervals are unnecessary. One dose a day is as efficient as several. It has been shown that the minimum dose necessary for sterilization in most cases need not be much exceeded in any case. By giving the dose just before bedtime, the discomforts of slight "quinism" are avoided. The drug is fully as efficient in compressed form as in solution. If the compressed drug cannot be swallowed, as may occasionally happen with children, syrup of yerba santa may be used to disguise the taste.

The oral administration of an undisguised acid solution is regarded as a barbarity, in which connection it is interesting to note that, according to Sir Ronald Ross, twenty battalions of British troops, infected with malaria, were put through a ten week's course during which 10 grains of the drug, in solution, were administered daily, under pressure of military discipline. This course was "designed and superintended" by Lieutenant Colonel Dalrymple. Possibly the use of this peculiarly nauseous method of exhibiting

the quinin was merely a result of the not rare indifference displayed by martinetts to the comfort of the soldier. Probably, however, the choice was determined by the greater ease with which the swallowing of the bitter liquid can be assured, thus avoiding "Skrimshanking."

Harrington and Barrier have studied quinin pepsin mixtures for the sterilization of malaria carriers. They report favorably on this combination. They claim that the incidence of "quinism" is reduced 70 per cent, without impairment of the sterilizing action. The following is the formula recommended, after trying a number of variants.

Quinin sulphate	90 parts (by weight)
Milk sugar	6 parts (by weight)
Powdered pepsin (U.S.P.)	4 parts (by weight)

Mix thoroughly and place in capsules No. 0 or No. 3. This gives practically 5 grains of quinin sulphate in each No. 0 capsule.

Prophylaxis by Quinin

This is a time-honored method and during its long career it has met its "knocks and boosts," has had its enthusiasts, and its detractors. The latter are at their last gasp. What is perhaps one dying sigh of opposition is breathed in a letter of the reminiscent order from the pen of Retired Mayor Porter of the Royal Army Medical Corps and dated from Bombay. Apparently his thesis is that quinin is not only of no use as a prophylactic, but is actually the cause of malaria.

Setting this aside, the enormous weight of evidence is in favor of the efficacy of the method. In an estate of some 11,000 acres at Marathon, Greece, by this measure, with almost no other means of control, the malaria index in school children was reduced from nearly 100 per cent to about 2 per cent in three seasons. Experience has been similar in many other parts of the world, where the method has been applied with equal thoroughness. The cost is small, the figure for the Marathon district being about 30 cents *per caput*. The difficulties are evident, and are greatest with a backward population, such as the colored inhabitants of the South.

The method of Bass consisted in the administration of 10 grains of quinin sulphate, morning and evening, on two successive days of each week, generally Saturday and Sunday, during the malarial season, in the particular instance from May to December.

The net result was a reduction of 64 per cent in the malaria morbidity as compared with the previous year, using the history, the medical call, and blood examination as checks. This measure cost 57 cents *per caput*.

The Efficacy of Screening

As a sole method of malaria control, screening was tried out in a typical rural neighborhood of Arkansas. At the commencement of the experiment, in May, 1916, 12 per cent of positive results was given by the blood examination of the inhabitants. In December the re-examination gave 3.5 per cent of positive results, the net reduction being 72 per cent of positive results at a *per caput* cost of \$1.75. The significance of the results was checked by parallel examinations of untreated, similar neighborhoods.

The screens used were sixteen mesh galvanized iron, and their life was estimated at two years. With reasonable use the average life ought to be three years.

Minor Anti-Mosquito Measures

These were exclusively used in a district of 2,029 inhabitants. After an initial survey upon which a mosquito breeding ground map was prepared, the following measures were carried out: ditches were rectified and kept clean; small ponds and borrow pits were filled in; marshes were drained; undergrowth was cleared; larger bodies of water were cleared of edge weeds and were stocked with top minnows; stagnant and sluggish waters were oiled. These operations were extended for half a mile outside the area under test.

The result was a reduction of 72 per cent in the plasmodium index and of 70 per cent in the calls of physicians to cases of malaria, as compared with the previous year. The *per caput* cost was 63 cents.

Efficacy of Measures About Equal

It will be seen that these measures are about equal in efficacy. Over one season a reduction of something like 70 per cent in malaria morbidity may be looked for from the exclusive but rigorous application of any one method. As might be predicted, experience elsewhere has shown that over several seasons the reduction runs in a roughly geometric progression.

The most expensive measure is screening, but, at \$1.75 *per caput* per annum, even this is not prohibitive. Owing to the increase in comfort resulting from the exclusion of mosquitos and flies, this measure is likely to be popular—something which can scarcely be said of systematic quininization.

The cumulation of all, or a combination of some of these measures, has generally resulted in a still greater one-season reduction. This was the case at Ismailia, and the experience has been repeated in many places where the instances have been especially favorable to control.

Some of these measures are better suited to urban than to rural districts. This is notably the case with the minor anti-mosquito measures which on an extended scale among scattered rural habitations would, in most cases, be impracticable.

Short of major drainage, therefore, the methods of choice in rural districts are screening and quininization. For the satisfactory application of the latter it is evident that for some time to come educational campaigns must play an important part. It would also be a part of the teaching to show the householders how to carry out, individually, some of the anti-mosquito measures that in towns are attended to collectively.

Mosquito and Malaria Control and Rice Cultivation

The conditions of rice cultivation are such as to render mosquito control of peculiar difficulty. For long periods rice stands in water, being practically a swamp grass. Hitherto this condition has been considered incompatible with mosquito destruction, and highly embarrassing to other methods of malaria control.

The two papers by Geiger and colleagues present a much more hopeful view. The first deals with experiments on mosquito control in rice fields; the second, with malaria control in a rice growing district.

In each of two farms five one acre plots were used for experiments. Five were set aside for controls and the following methods were tested, with the result shown:

1. Fuel oil from drip can at water inlet.
2. Two-plus-one mixture in the same way. These two methods failed. The oil was held up, near the source, by the rice stalks and failed to spread.
3. Sawdust saturated with the same oils. This gave satisfactory distribution and larvicultural action without injury to the crop.
4. Introduction of top minnows. Although the minnows congregated in the deep water near the inlet and along the levees, the results were not altogether unsatisfactory. There was a great reduction in the number of larvae, and no large larvae or pupae were found. Probably, therefore, the fish devoured the mature larvae and those found were not of significance from the public health standpoint.
5. Intermittent flooding was tried, but cannot be regarded as a practical measure on account of the expense, and because of the

impossibility of removing the larvae, by this means, beyond the flight limits.

The second paper covers with great detail the practical points in malaria control in a rice growing district. Lonoke has a population of 1,500. In 1917 29 per cent of the population were infected with malaria, with four deaths. In 1918 there was one case of malaria and no deaths from that disease.

The measures which produced this remarkable result are detailed in this paper. They were: sterilization of carriers by the administration of 10 grains of quinin sulphate a day for 30 days; screening; and mosquito control.

The discovery during this work of nineteen persons whose blood contained plasmodia, but who presented no clinical signs or history of malaria emphasizes the need for adequate blood examinations and for sterilization of carriers. The same point is brought out by Bass in his paper No. VI.

In the course of this work observations of capital importance on the flight of engorged female anophelines (*A. quadrimaculatus*) were made. The greatest flight recorded was one mile. The maximum flight yet observed is 1.7 mile.

Economic Loss Due to Malaria

"We Americans are paying \$100,000,000 each year for the privilege of having chills and fever," says LePrince. In a survey of three typical Texas rural communities, containing 179 white and 119 negro families, the annual cost of malaria was estimated at \$12,000. Applying this to the part of the population of Texas similarly exposed we arrive at \$10,000,000 as the *direct* annual loss.

Gray made a house-to-house canvass in a California district, with a population of 1,300. The district was valley and foothill land on each side of the Sacramento River, having an area of 32,000 acres. About 56 per cent of the population had malaria in 1918. The direct cost to the families in labor loss, medical service, and medicine was \$10,400, or \$31.70 per family per annum. The indirect cost cannot be readily estimated, but one item of it, the depreciation of property values, is conservatively estimated at \$250,000 for the fifty square miles.

In this locality the malaria is subsequent to and certainly caused by irrigation, particularly by seepage from a canal running along the shoulder of a slope. In such a case major operations would be justified and would, even on the present basis, cause such an appreciation as would repay the expenditure in four years. The estimated costs are: First year \$22,000, of which

\$12,000 is for agricultural drainage and correction; second year, \$5,000; third and subsequent years, \$3,800.

For details of the technic of the blood examinations and of the anti-mosquito measures, the reader is referred either to the papers here reviewed or, better, to a very important report on malaria control published in the Public Health Bulletin. An immense amount of valuable information is to be found in the two pamphlets by Hoffman published by the Prudential Insurance Company of America.

CLINICAL CONGRESS OF SURGEONS

The Clinical Congress of the American College of Surgeons, organized ten years, has realized its main objectives in demonstrating to picked members of the profession the highest standards of surgical and hospital methods, and in promoting a close fellowship between the American and Canadian surgeons whose professional ethics and morals are unimpeachable. Their Ninth Annual Convention in New York, October 20 to 25, has been of unusual interest. The collective clinical material of this center is not surpassed by any other city in the world, while the added stimulus of war work and certain changes of scientific arrangements and medical thought will give new interest to the proceedings. The work in standardizing hospitals, with which the American College of Surgeons has identified itself, will receive a distinct impetus, as the hospital demonstrations are staged to work under conditions that are ideal from every angle and the observing surgeons will be prompted to duplicate these facilities in their own hospitals and cities. John D. Clark, M.D., of Philadelphia, made the burden of his message as retiring president the urgency of strengthening of medical teaching researches, particularly facilities for post-graduate work and for facilities for research. He

says the practical ability of the American surgeon should be supplemented by a fine sense of research. The program of the Clinical Congress appears elsewhere in these pages.

Among the prominent surgeons in attendance are Sir Arthur Bowlby of London, Sir Robert Jones of Liverpool, and Major Gillies of Sidecup.

CENTRALIZATION OF HEALTH ACTIVITIES

In a recent speech before the Royal Society of Medicine discussing the English Industry of Public Health, as reported in the October issue of the *Canadian Journal of Medicine and Surgery*, Sir William Osler ably discusses the urgent need of consolidating and coordinating the various departments which deal with public health. He charges the medical profession with the "intellectual weakness in high places" which has suffered the pace to be set by "organized ignorance."

Three critical and contentious points are emphasized which are of universal interest and characterize the issues here as well as in England. The insurance, tuberculosis, syphilis, maternity, and child welfare legislations have brought the state to the door of the practitioner and "willy-nilly," he has become in some measure the public servant.

The first point of contention is stated in the form of a question: "Is the scheme possible in which the physician is a paid official of the state; yet independent—a civil servant, yet alive to the needs of science?" Doctor Osler fears the effect of such a scheme upon the competition which has played so important a part in the profession for the last 2,500 years. "It may be possible," he says, "to work out such a scheme, but not, I trust, at the sacrifice of the independence of the independent practitioner."

The second point in his discussion relates to the relation of the state to research. Even the brilliant work which has been accomplished in preventive medicine has been unable in certain quarters to overcome an invincible prejudice against state aid. There are no grounds whatever, says Doctor Osler, for this distrust. Aside from the achievements of the Lester Institute, practically all the first-hand discoveries in the fields of infections have been made by men in official harness. He considers the debt of the profession one hundred fold greater to the Government for its researches in preventive medicine than to all the universities combined. "All such objections," he says, "are sufficiently answered by the series of splendid monographs issued during the war by the National Research Committee."

The third question, "The Hospital in the Scheme," has caused even more dissension. It seems to be the consensus of opinion that in any place the hospital should form the center, or the unit, around which the general practitioners should unite and form a thoroughly working combination of all the voluntary agencies within the state. The difficulties of attaining this ideal are sensed by all.

The advantages of such organization would be chiefly in the development of clinical men. "The clinical consultant," says Osler, "should be a life time man with a good salary. He should have a hospital of from eighty to one hundred beds with the control of out-patients and a staff of paid assistants. He would see the special cases sent from neighboring doctors, and direct the work in the clinical laboratories." The benefits of such an organization are apparent, as "we all know that pure medicine as a study has not of late been fostered in our county hospitals, some of which are still without the essential

clinical laboratory." The consultant would be the center of social service work, which would make the out-patient department the strong arm of the hospital in its relation to the public. A centralized department of health, backed by a united profession could undertake important reforms which at present seem hopeless.

SOUTHWESTERN TUBERCULOSIS CONFERENCE

The fourth Southwestern Tuberculosis Conference held at Long Beach, Cal., October 1 to 3, was undoubtedly the most successful meeting since the organization of the conference district, from the standpoint of program as well as attendance. Papers were presented by workers from tuberculosis and health organizations in the states of Arizona, California, Colorado, Kansas, New Mexico, Oklahoma and Texas and were supplemented by addresses by health workers of national repute. The conference registered in a most forceful manner the great progress made in the anti-tuberculosis campaign particularly in the southwest.

The first days' sessions dealt largely with the question of occupational therapy for the tuberculous. This subject was introduced by a very able paper read by Dr. H. A. Pattison, medical field secretary of the National Tuberculosis Association, on "Occupations for the Tuberculous." The paper showed the result of careful research on the after care of the tuberculous and suggested the advisability of an industrial community for arrested cases of tuberculosis. Other phases of the subject were discussed by Miss Mertice C. Buck, vocational instructor of the California Tuberculosis Association and Miss Agnes L. Murray, divisional director, Bureau of After Care, American Red Cross, Denver.

A symposium on public health nursing on the second day, was led by Mrs. Bessie A. Haasis of the National Organization for Public Health Nursing with a timely paper on "Application of Teaching Principles to Public Health Nursing." The general discussion which followed the exposition of some elementary principles of educational psychology opened up a new field for thought for the nurses and other workers present.

A report of the National Committee on the Indigent Migratory Consumptive was presented by its secretary, Dr. Severance Burrage, of Denver. Considerable interest was evidenced in the progress noted in the report, and much valuable data on the subject was introduced in the discussion by Dr. Philip King Brown, San Francisco; D. E. Breed, Austin; and Mrs. E. L. M. Tate-Thompson, Sacramento.

A departure from the general conduct of the conference was the holding of a special medical section. This was held under the chairmanship of Dr. Philip King Brown, of San Francisco. The medical session included papers by Lieut.-Col. Alexis Forster, Colorado Springs; Dr. James A. Miller, New York City; Dr. Mary Jones Mentzer, San Francisco; Dr. L. J. Moorman, Oklahoma City; and Dr. John W. Flinn, Prescott, and others. The experiment of having a special medical section was generally acclaimed to be a success and will probably be repeated in future conferences.

A unique feature of the sessions was an Americanization Clinic conducted by Dr. James A. Miller, of New York City, in which he demonstrated the many factors to be considered in dealing with patients of foreign birth. His subjects were patients of Mexican, Indian, Japanese, and Greek nationalities.

At the evening session, open to the general public, ad-

dresses were made by Dr. Livingston Farrand, chairman of the Central Committee of the American Red Cross; Dr. Jas. A. Miller, New York City, and Dr. William Palmer Lucas, Berkeley. Doctor Farrand's subject was "The Health Program of the American Red Cross." This was the first time in which these three noted health workers appeared on the same platform since their return from France.

Other subjects considered at the Conference were the Modern Health Crusade and the selling of Red Cross Seals. The 1920 meeting will probably be held in Dallas, Tex.

AMERICAN JOURNAL OF NURSING

Editorial comment in the September, 1919, issue of the *American Journal of Nursing* makes note of the appointment of Miss Clara D. Noyes as director of the department of Nursing of the American Red Cross to succeed Miss Delano, in whose place she has been acting director.

In the same issue S. J. Crumbine, M.D., presents a paper on the "Socialization of Preventive Medicine Through the Public Health Nurse," in which he exalts the public health nurse to the rôle she must assume as nurse, diplomat, reformer, and judge in the various functions she must perform.

The "Social Work of Industrial Welfare Nursing," is discussed by Frances McGee. The first aid room is by preference as close as possible to the men's work, no small part of prevention of serious consequence being dependent upon prompt care and upon the proper handling of minor injuries. The function of the industrial nurse varies with the industry and the lines she is hired to develop, but there is always educational work to do and she must possess the social spirit. An industrial nurse of the right type offers a lower insurance rate, continuity of service, contentment and loyalty. The men find in her a friend in need and a social interpreter.

C. C. Pierce, M.D., of the United States Public Health Service, discusses "The Nurse as a Factor in the Prevention and Control of Venereal Disease." Because public health work is of necessity carried on in and through cooperation with the various state boards of health and because the venereal diseases are so interwoven with every other physical and social ill of the people, the direct educational and constructive measures necessary for the control of venereal disease depend largely upon the nurse. The most urgent problem is not to determine the potential usefulness of the nurse in this connection, but to find a sufficient number of women with the special training necessary to do the work. Schools are reminded of their responsibility in the matter and institutions are urged to provide for the proper hospitalization of such cases.

The standards of "Pre-Hospital Training for Nurses" in the fundamental sciences are outlined by W. D. Christian, M.D., of Richmond, Va. He recommends that the summer schools in medical colleges provide brief practical courses for nurses. Very definite scientific training is necessary in this vocation and it is essential to provide the mental discipline and the power of nice observation these studies promote.

Other articles of interest are: "The Need of Cooperation Between the Head Nurse and the Instructor," by Permilia Murnan Doty, and "The Establishment of Foreign Training Schools," by Clara D. Noyes.

Parasites on human society are not many; and they are to be pitied, for they never know the joy of work.—Robert W. Mackenna in "The Adventure of Life."

BOOKS OF THE MONTH

Comment on Current Medical and Health Literature and Announcements of New Books

HANDBOOK ON SANITATION. A Manual of Theoretical and Practical Sanitation. For Students and Physicians; for Health, Sanitary, Tenement House, Plumbing, Factory, Food, and Other Inspectors; as well as for Candidates for all Municipal Sanitary Positions. By George M. Price, M.D., author of "Tenement House Inspection," "Epitome of Hygiene and Public Health," "Hygiene for Nurses." Director of Investigations, New York State Factory Commission; director of Joint Board of Sanitary Control, etc.*

Primarily intended for practising health, sanitary, tenement and other inspectors, and only secondarily for students hoping to become inspectors, this book succeeds in its first aim, but is rather weak in its achievements relating to the second.

It is divided into three main sections, Sanitary Science, Sanitary Practice, Sanitary Inspection as a Profession and an Art. It ends with about thirty pages of civil service examination papers for New York positions and a collection of tables, data, and definitions, useful to inspectors of all the kinds mentioned.

Brief, concise, conventional, dogmatic, giving little discussion or explanation for the student, it covers pretty well the chief points that the ordinary inspector requires. It is not properly a handbook of sanitation, but of inspection; and it relates chiefly to those items of building construction and equipment; of water, food, and air supplies; and of waste disposal systems, which by tradition, or in fact, relate or are supposed to relate more or less to the health of humans.

It is thus a systematic aggregation of rules of practice in the sanitary inspections of today rather than a treatise on the subject of the relations of surroundings to physical welfare; and it will appeal chiefly to that type of mind which prefers the memorizing of concrete statements, however unrelated they may appear to be, than to that type which demands a complete understanding grasp of the subject as a whole.

Numerous very general statements are made, describing "unsanitary" conditions as "dangerous" to health or life, but there is little or no attempt to correlate any definite factor in the unsanitary conditions with any specific injury to the human.

Modern sanitation is in a state of flux; properly, details of sanitation should be advocated or condemned as they react favorably or otherwise on the physiological operations of the humans concerned; and the relationship between a given bad or good condition in the surroundings and the physiological harm or benefit it achieves should be made clear and definite in a modern text-book, for the day of glittering generalities is nearly over, we hope.

Some rather odd statements are made; as for example, page 50, that "whether there is a public water purification plant or not, every individual household should provide some means of local purification" (reviewer's italics).

This statement certainly implies a remarkably frank skepticism of modern municipal water purification on the one hand, and, on the other, ignores the uncounted naturally pure supplies used by nearly half the population, i. e., from springs and wells.

In specifying methods of private water purification, boiling is advocated as the cheapest, most available, and most efficient, but no one who has passed through a siege of boiled water, as during a water-borne epidemic, will agree very enthusiastically with this statement, except as to its (theoretical) efficiency. Since no community, even in an epidemic, ever does carry it out uniformly, thoroughly, all the time, its practical efficiency is low, except insofar as the ordering of boiling is a soothing balm to the health officer's conscience.

To advocate boiling of all water, all the time, from all sources, pure, purified or otherwise, would entail an almost intolerable, and quite unnecessary burden; and binding unnecessary burdens is one crying sin of the older sanitation we moderns should scrupulously avoid.

Our author avoids any reference to impounding waters —perhaps the most conclusive method of purification we possess.

We believe that the author should expand the theoretical side very much and connect it with the practical, for the use of students; or, on the other hand, omit entirely the present superficial, inadequate, and sometimes misleading explanatory statements offered, leaving the concrete details as a good compilation for inspectors in practice.

WHAT IS AMERICA? By Edward Alsworth Ross, professor of sociology, University of Wisconsin. Author of Social Control, Social Psychology, etc.†

In these days of stress and turmoil the placid little book of Professor Ross makes delightful before-going-to-bed reading and invokes most pleasant dreams. You see, for example: Labor surrounded by such dignity and "so respected that a national holiday, Labor Day, is set aside in its honor" and all this in spite of the fact that "before the war nearly half of the men in organized industry earned less than \$600 a year, while four-fifths received less than \$750." You see a society which has attained "a fair degree of success in the control of the sex relation" as testified by "the fact that out of a hundred white children ninety-six or ninety-seven are born in wedlock." You forget for the moment the clamorous claims of "birth control" for open recognition, and the somewhat disquieting figures of the social hygienists to the effect that 15 or 20 per cent of the population is syphilitic and 70 per cent of males have had gonorrhea at least once in a lifetime.

*John Wiley & Sons, Inc., New York. \$1.50.

†The Century Co., New York, 1919.

The stupendous strides America has made of late on the road toward better health organization find only a very faint echo in Professor Ross's little book. Having written the book in 1919, Professor Ross is frequently compelled to use statistical information almost ten years old. With the rapid tempo of modern life a decade is a long lapse of time. It is to be hoped that this interesting summary of American life will be enlarged and brought up to date when the results of the new census become available.—E.H.L.C.

PLASTIC SURGERY, ITS PRINCIPLES AND PRACTICE. By John Staige Davis, Ph.B., M.D., F.A.C.S., Instructor in Clinical Surgery, Johns Hopkins University.*

To this book probably belongs the distinction of being the first systematic text limited to plastic surgery. The author states in his preface that the purpose of the volume is to show the general practitioner the possibilities of plastic surgery, and to start the student, or beginner, on the right track. With this in mind, he has gone more carefully and with more detail into the general considerations and principles treated in the early chapters; for example, chapters IV and VI, on the "transplantation of skin" and "pedunculated flaps," are written most simply and clearly. The special attention paid this particular section of the book suggests the author's peculiar interest and very wide personal experience. Under the chapter on the treatment of wounds, debridements, and the newer antiseptics and their methods of application are discussed briefly, serving well to summarize the abundance of literature on these subjects produced during the war.

I can not agree with the author that a general anesthetic is necessary in the injection of a hemangioma with boiling water. I have personally watched Dr. John Wyeth inject these tumors painlessly under local anesthesia, and, during my association with Dr. R. E. Farr, we have repeatedly made satisfactory injections by the same method.

The author barely mentions the splendid work and technic of Doctor Brophy in the closure of cleft palate, but states that he has never felt justified in using the method.

The reviewer's experience coincides with that of numerous other surgeons who have been called upon to do a wiring or crushing operation on older children or adults, on whom a closure of the lip had been first done with the intent of drawing together the front of the cleft. In all of these cases not only was the cleft not closed but the uncorrected deformity required radical and extensive bony reconstruction. However, visits to the clinics and study of the writings of Sir Arbuthnot Lane, and Colonel Fagge, his associate, who now does the cleft palate operations at Guy's Hospital, and, also, of Mr. Berry, of the Royal Free Hospital in London, disclose the fact that there is a marked and legitimate divergence of opinion as to the proper methods of operating, and the logical sequence of operations. After a visit to Brophy's clinic and an observation of his end results, one must conclude that he comes the closest to restoring the normal bony arch and, consequently, the facial contour.

The author is to be congratulated on the excellence and clearness of the many illustrations. The bibliography at the close of each chapter indicates much painstaking effort, is a valuable adjunct, and should serve as an excellent reference to the reader who wishes to go more deeply into the literature on any particular subject. This

volume should form a valuable addition to the library of any medical student, surgeon, or medical society.

THE PRACTICE OF PEDIATRICS. By Charles Gilmore Kerley, M.D., professor of diseases of children, New York Polyclinic Medical School and Hospital.†

It was a happy thought on the part of the author to dedicate his book to the practitioner students, for this book appeals primarily to the practising physician who seeks in a text book on any subject practical and simple suggestions in the treatment of various disorders. The value of the book is evidenced by the many times it was reprinted since its appearance in 1914. It shows that the practitioners of the country use it and like it. A suggestion or two might, however, not be out of place. While the reader expects to get the personal experience of the author, the "I" of the book is a little overdone. The author repeats too often that he has seen this, that he has treated so many cases of a certain disease, something that is taken for granted by the reader who comes to this text for advice.

The classification of diarrhea is probably a little old-fashioned. We can no more put all gastrointestinal disturbances into a narrow frame of acute gastritis, acute gastroenteric intoxication and mucous colitis. One does not necessarily have to follow the Finkelstein or Czerny classification of alimentary disturbances, but the scope of diarrhea in infants must be wider than the one put forth by Kerley. Nor can everybody agree with the author that diarrheas should be treated by calomel.

These suggestions, however, do not detract much of the general usefulness of the book, which is of great value to the student and practitioner alike.

WHAT WE KNOW ABOUT CANCER. A Hand-book for the Medical Profession. Prepared by a committee of the American Society for the Control of Cancer.‡

The American Society for the Control of Cancer has been in existence and working effectively for a number of years, having for its object the "dissemination of facts in regard to cancer to the end that its mortality may be reduced by a wider knowledge of the disease."

The effort represented by the present pamphlet has perhaps the most far reaching possibilities for good of any single attempt to lessen cancer mortality undertaken in this country.

It is no longer necessary to argue the point that delay is the one great factor in cancer mortality. At least four-fifths of cancer deaths could be prevented by early recognition. The conditions necessary for recognition of cancer in ample time for cure are not ideal but distinctly practicable. Public education is one important pathway of improvement, but education of the medical profession itself is of equal if not greater importance. Statistical studies have shown that in the majority of cases the doctor has had the cancer patient "under observation" over a year before efficient curative treatment is instituted. During this year the majority of change from curable to incurable. As the pamphlet somewhat mildly puts it, "The conditions call for a far keener appreciation of responsibility for the mortality from cancer than now generally exists in the medical profession." . . .

"The annual increase in the cancer death rate is approximately $2\frac{1}{2}$ per cent. The recorded cancer death rate has practically doubled during the last forty years."

Men and Women Who Begin Each Day Only Half Rested are Rarely, if Ever, Efficient Workers

WORRIES, indigestion, improper food and poor ventilation are the common causes for a "poor night's rest." But, noisy, uncomfortable beds are also to blame for this condition.

Most physicians, public health officials and industrial welfare workers now realize the importance and health-building value of sound, restful sleep. Every time they impart this knowledge to those who still cling to old-fashioned notions regarding beds, springs and close, "stuffy," poorly ventilated sleeping rooms, they are contributing to the cause of public health.

Sound, healthful sleep—the sleep that restores, invigorates and fits one for the next day's activities—depends as much upon the choice of bed and bedspring as it does upon proper sleeping room arrangement and fresh air.

Simmons Beds are first of all designed and built on the principle that *a bed is made to sleep in*.

They are so constructed as to entirely eliminate the common faults of the old style bed that creaks, groans and rattles with every turn of the sleeper, which de-

feats his or her chances of quiet, and causes that feeling of unstableness which prevents complete relaxation.

Simmons steel beds are *noiseless*. They are strong and hold firm where the average bed is weakest and most "ricketty"—*at the corner locks*.

For the corner locks on Simmons beds are made of pressed steel, with a longer bearing surface than that of other corner connections. Each part—head, foot, side rails and all—fits true and snug, so rigid that the bed when moved, *moves as one piece*.

It is beds of this type that are contributing so greatly to the comfort, health and efficiency of modern business and industrial workers. Everybody can afford and will enjoy better sleep in a Simmons Bed.

Hospitals and institutions are equipped with Simmons Beds. Schools, colleges, Y. M. C. A.'s and industrial dormitories are provided with them. Supremely restful, sanitary and serviceable, Simmons Steel Beds in any one of half-a-hundred styles and prices, completely solve the sleep, health and efficiency problems of the people.

Data Regarding Simmons Beds, Bedspring Equipment for Public, Semi-Public, Institution, Industrial, Recreation or Outdoor Camps, will be promptly provided upon request.

SUBSCRIPTION

Domestic postage, \$3.00. Foreign postage, \$3.50 (15 shillings). Single copies (regular), 25 cents.

Domestic rates include United States, Cuba, Mexico, Porto Rico, Canal Zone, Hawaii, and Philippines.

SUBSCRIPTIONS.—Subscriptions may begin at any time. Volumes begin January except in the case of Volume I, which consists of the numbers issued during 1919 (May to December, inclusive).

REMITTANCES.—Remittances for subscriptions should be made by check, draft, post office or express money order, or registered letter. Make all checks and money orders payable to MODERN MEDICINE.

CHANGE OF ADDRESS.—Notice of change of subscriber's address should give both old and new addresses. Notice should reach us fifteen days in advance of date of publication.

COMMUNICATIONS.—When communications relate to more than one subject (manuscript, reprints, subscriptions, news items, etc.), correspondents will confer a favor by writing on a separate sheet for each subject, thereby insuring more prompt attention.

ADVERTISEMENTS.—The advertising pages of MODERN MEDICINE are available for announcements of anything of interest and service to those engaged in the treatment and care of the sick and especially to those who are devoting their efforts to organized medical and health work. Advertisements of secret remedies and other objectionable announcements will not be accepted. The supervision of the Editors is extended to the advertising columns, in which only approved products and reliable manufacturers will be represented.

CLOSING OF FORMS.—Advertising forms close on the 10th for the issue of the following month. Ample time should be allowed for composition of advertisements and the sending and return of proofs.

ADVERTISING RATES.—Advertising rates will be sent on request.

CONTRIBUTIONS.—Original articles on any problems of practical interest to our readers are respectfully solicited from those who can write authoritatively on current problems in social medicine, hygiene and medical service in industry, public health and allied subjects. Articles are accepted for publication with the understanding that they are contributed solely to MODERN MEDICINE.

ILLUSTRATIONS.—Such half-tones and zinc etchings as in the judgment of the Editors are necessary to illustrate articles will be furnished when photographs, drawings, or ink tracings are supplied by the author.

NEWS MATTER.—Our readers are requested to send in items of news, and also marked copies of newspapers containing matters of interest. We shall be glad to know the name of the sender in every instance.

BOOKS OF THE MONTH

(Continued from page 650)

It is not possible here to abstract this pamphlet which is already so condensed. The general facts concerning cancer are outlined and then each important type and site of cancer is taken up in detail and the forms, symptoms, standard treatment, and results to be expected are outlined for each type. The ultimate possible good obtainable from the widespread dissemination of this pamphlet is so great that we would urge every possible means to get into the hands of as many medical men of all classes as possible.

Boards of Health, both state and municipal, and medical societies should aid in distributing the pamphlet. When such a simple means for such far-reaching good is available it should not be neglected.

AN INTRODUCTION TO NEUROLOGY. By C. Judson Herrick, Professor of Neurology in the University of Chicago. Second edition, revised.*

The first edition of this book received a deserved favorable reception by the medical profession. In the second edition there has been no departure from the original plan of the work, but it has been thoroughly revised and somewhat enlarged. This edition will surely meet the same favor as was accorded the first.

GENITO-URINARY DISEASES AND SYPHILIS. By Henry H. Morton, M.D., F.A.C.S. Fourth edition, revised and enlarged.†

A handbook which reaches its fourth edition in this day of prolific writing carries its own best endorsement. Morton's book covers as completely as possible in one sizable volume the subject of genito-urinary diseases and syphilis. The illustrations are satisfactory and the colored plates especially meritorious.

LABOR AND RECONSTRUCTION IN EUROPE. By Elisha M. Friedman, Editor of "American Problems of Reconstruction."‡

The volume furnishes a valuable report on labor reconstruction agencies and plans for labor reconstruction in most of the European countries, largely Great Britain, as more than half of the 200 pages of the book are devoted to a discussion of the labor reconstruction plans of England.

In its subject matter the book covers two principal topics: (1) agencies charged with the problem of readjustment, and (2) specific adjustments suggested and attempted. Aside from covering the subject of labor adjustment in allied countries, the author attempts also to discuss labor reconstruction in the countries of the central powers—Germany, Austria, and Bulgaria. In the latter connection, however, the author realizes the relative unsatisfactoriness of his work due to the absence of the needed documentary data.

The volume shows the existence of some reconstruction agency or other in almost each of the principal countries of the world. No reconstruction agencies, apparently, exist in China and Turkey. These countries have apparently followed the original lead of the United States in hoping that the labor and economic results of the war will automatically readjust themselves. The author, in

An Ideal Antiseptic Combination

for Gargle, Mouth-Wash, Nasal and Throat Sprays

Fresh solutions can be instantly prepared with measuring cap on bottle.

This new combination of CHLORAZENE, sodium bicarbonate, sodium chloride and Eucalyptol, has been an immediate success, because of its

1. Powerful Antiseptic Action.
2. Safety.
3. The Solvent Action of Sodium Bicarbonate.
4. The Cleansing Action of the Salt.
5. Pleasant Aromatic Properties.

Colds, Influenza

Doctor, try Aromatic Chlorazene Powder in colds, sore throat, infections of the mouth, gums and nasal passages.

Use it for cuts and wounds; as a douche and application wherever a powerful, non-toxic antiseptic is indicated.

A Sample Free

Send at once for a Free sample bottle of Aromatic Chlorazene Powder for a clinical trial. You will find it a success-maker. For sale at all druggists.

The Abbott Laboratories

Home Office and Laboratories, Dept. 27

New York San Francisco Seattle
Los Angeles Toronto Bombay

BOOKS OF THE MONTH

(Continued from page 22)

a fair and impartial manner, calls attention to the fact that while there is unanimity with reference to the necessity for a scientifically systematic labor reconstruction, the methods to be used in arriving at the desired result vary with (1) the relative position of the various schools of thought represented in the existing political parties, and (2) variations due to the specific economic position of the country in question. The book gives a very interesting account of the various economic questions which Germany, England, and France are attempting to solve in the respective fields of their labor reconstruction work.

The volume contains a comprehensive bibliography and reproduces verbatim a considerable number of original public documents, some of which have not as yet been published in an easily available form. In this respect it is performing a very useful function which has only partially, although thoroughly, been covered, by the United States Bureau of Labor Statistics in its publications known as the "Labor as Affected by the War" series.

DISEASES OF THE SKIN. By Richard L. Sutton. Second edition revised and enlarged.*

The second edition of Sutton's book, as anticipated, is an excellent volume, for the student, practitioner, and as a reference book for the specialist in skin diseases and syphilis. The careful and painstaking exposition of the histopathology of the various dermatoses stands out as one of the best features among many excellent ones in this handbook. One seldom sees between two covers a volume so free from chaff. It is most heartily endorsed.

CREATIVE IMPULSE IN INDUSTRY, A PROPOSITION FOR EDUCATORS. By Helen Marot, Author of "American Labor Unions."†

This little book by Miss Marot is so full of thoughts and ideas as to make a review of it difficult. To be appreciated it should be read and studied by all who are interested not only in education but in the stupendous problems of industrial readjustment now facing this country. Intelligence of thought, logical pursuit of deductions, and the flowing style make this book a fascinating piece of literature. One may not agree with everything the author says but, whether agreeing or not, there is so much food for thought in the book as to make it a most valuable contribution.

ANIMAL PARASITES AND HUMAN DISEASE. By Asa C. Chandler, M.S., Ph.D., Instructor in Zoology, Oregon Agricultural College, Corvallis, Ore. First thousand.‡

"It is the belief of the writer that one of the most pressing needs of the present time is the education of the people as a whole in the subjects of vital importance with which this book deals, and an increased interest in this field of scientific work." It is, indeed, a pleasure to read through this book and see how well the author has achieved his object. The reviewer believes that there is no field of medical literature more important than public health education. The subject, however, is difficult to present and many so-called popular books are either unscientific or full of fallacies meant to appeal to popular prejudice. This book, while thoroughly scientific, is written in a readable form, is thorough, and certainly is a most valuable contribution for parasitologists, public

health and immigration service officers, physicians, teachers of hygiene or domestic science, students, travelers, and "to the farmer or merchant who is interested in the progress of science and civilization."

SURGICAL THERAPEUTICS AND OPERATIVE TECHNIQUE. By E. Doyen, in three volumes, English Edition prepared by author in collaboration with H. Spencer-Browne, M.B., Cantab., etc. *Elève de l'institut Pasteur; Physician, and Chef de clinique de l'institut Doyen.*§

Doyen's *Surgical Therapeutics and Operative Technique* comprises three volumes, of which only the first two have been received by the reviewer. As the title indicates, the treatise covers the realm of general surgery from a therapeutical standpoint. Diagnosis is not dealt with.

Volume I contains an introduction with a brief review of the surgery of the nineteenth century. A section on general surgical technic deals with the fundamentals, incision, clamping, suturing, etc. The author describes his surgical institute. The remainder of the volume is devoted to the typical operations of the cranium, brain, sinuses, and, also, operations on the eye, ear, nose and throat.

Volume II takes up the regional surgery of the head, neck, thorax, and extremities. Only one operation of each type is described, namely, the operation used by himself. Very little reference is made to the work of other writers. The reader will probably be disappointed in not finding any bibliography. The index lacks detail, but it is possible that an index, covering the entire work may appear in the last volume.

The books are translated, or, rather, transcribed into English by Doctor Spencer-Browne. The English is clear and the matter presented in a readable form. The various sections are profusely illustrated, diagrams and photographs being liberally used.

Doyen's profound knowledge is apparent to even a casual reader. The reader visualizes the eminent French surgeon, boldly proclaiming his theories, carefully diagnosing his cases, and deftly operating in his own surgical amphitheater.

Doyen is a bond between the past and the present. He is an ardent admirer of the manual dexterity of the old surgeons who, without anesthetic, performed a variety of difficult operations. He describes the long, slow technic which many modern operators have adopted. Although realizing the importance of preventing loss of blood, he is opposed to the tedious methods of hemostasis often practised.

As a general surgeon, Doyen has little use for "over specialization." He believes that a man who can perform a skillful pyloric operation would also be able to perform successfully an operation on the uterus. Judging from his books, Doyen's hobby is his armentarium. Much space is devoted to instruments, many of which he has designed or modified himself. Each chapter contains a complete list of instruments which may be needed and usually also a photograph showing how they might be laid out for the various operations.

The books will be an interesting addition to a well stocked library, but as reference books for the student, or pathfinders for the young surgeon, the reviewer doubts

MEAD'S DEXTRI-MALTOSE

Has filled a want in infant feeding as the most efficient means of supplying the deficiency of carbohydrate in diluted cows' milk. Its universal use

Has Become a Part of Modern Infant Feeding

To meet the requirements of the individual baby MEAD'S DEXTRI-MALTOSE is made in 3 forms (No. 1, No. 2 and No. 3)

No. 1. With Sodium Chloride, 2%—For general use in the diet of infants. It may be substituted in the same proportion for either cane or milk sugar in any good system of feeding.

No. 2. Unsalted—Prepared for those physicians who prefer to make their own salt additions. Also of special value in the diet of adult invalids.

No. 3. With Potassium Carbonate, 2%—Valuable where constipation is present. Potassium carbonate acts as a corrective by softening the fecal matter.

Made expressly for Physicians' use

MEAD JOHNSON & CO., EVANSVILLE, IND.

Basic Principles Embodied in the Construction and Design of the New York Study Chair

First—A movable seat and desk in one unit.

Second—A seat modeled to the normal shape of the thighs and buttocks, allowing thereby the pelvis to rest on the normal weight-bearing surface of the tubera ischii, and thus avoiding forward slipping of the pelvis with its forward rim tilting upward and consequent distortion of the spine.

Third—A seat adjustable to height.

Fourth—A back so formed as to allow the occupant to maintain the torso in the normal erect position.

Fifth—A movable back support, convex forward, that will maintain the normal forward lumbar curve and compel an erect position of the entire spine.

Sixth—A back of proper height with a top cross bar to prevent round shoulders.

Seventh—A desk that can be easily adjusted to any desired position, height or angle for drawing, reading or writing.

Eighth—A back, seat and desk, so correlated as to give a correct and yet comfortable "set-up" to the occupant when at work.

BOOKS OF THE MONTH

(Continued from page 24)

whether Doyen's *Surgical Therapeutics and Operative Technic* will be popular.

CLINICAL MEDICINE FOR NURSES. By Paul H. Ringer, A.B., M.D., member of staff of the Asheville Mission Hospital, Asheville, N. C., and of Biltmore Hospital, Biltmore, N. C.*

This little volume presents lectures on medical diseases delivered by the author to the nurses of the hospital with which he is connected. It seems that his aim to place in concrete form a fairly detailed description of all important facts has been carried out successfully. This new book might well serve as a basis upon which class-room lessons can be assigned and quizzes held.

A MANUAL OF GYNECOLOGY. By John Cooke Hirst, M.D., associate in gynecology, University of Pennsylvania; obstetrician and gynecologist to the Philadelphia General Hospital.†

Short manuals clearly reveal the author's personal judgment concerning the relative importance of the various topics which constitute the entire subject he endeavors to present in a thorough and at the same time concise manner.

It is interesting to note that in this small volume relatively more space is devoted to the consideration of leukorrhea, the operation of cervical dilation and curettage, the pathological sequelae of childbirth and endocrine gland therapy. One can readily appreciate this preferential choice in a manual designed for and dedicated to the undergraduate student. Some doubt, however, will be permissible concerning the wisdom of including, as Hirst does, special chapters dealing with the diseases of the urinary tract, of the rectum, and even with the diseases of the breast, in a manual of gynecology for which brevity and the elimination of all non-essentials are emphasized by its author as the chief characteristics.

THE MEDICAL AND SURGICAL ASPECTS OF AVIATION. By H. Graeme Anderson, M.B., Ch.B., F.R.C.S., Surgeon Lieutenant, Royal Navy; Surgeon, Royal Air Force Central Hospital; senior assistant surgeon, Belgrave Hospital. With chapters on applied physiology of aviation by Martin Flack, M.A., M.B., Lieut. Colonel, R.A.F., Director of Medical Research to the Royal Air Force; and the Aero-Neuroses of War Pilots by Oliver H. Gotch, M.B., Ch.B., M.R.C.P. (London). Surgeon Lieutenant Royal Navy, Royal Air Force Central Hospital; and an Introduction by the Right Hon. the Lord Weir of Eastwood P.C., Secretary of State for Royal Air Force.‡

Medical literature is not replete with works of this character, for which reason this book is all the more welcome and for this reason, also, the classification of the subject is largely pioneer work. The author is not overburdened with his own importance, has a clear conception of the subject, is a simple writer commanding easily understandable English, and in view of these facts has given us a work that is of distinct value, not only to the medical officer but to the aviation pupil.

The chapters on the psychology of aviation, the aero-neuroses, aeroplane accidents, the surgery of aviation, and the selection of candidates for aviation are very interesting and instructive. The authors have also included articles dealing with history of medical interest

Virol is a British preparation and is held in highest regard by medical men. It is indicated in marasmus, rickets and all cases requiring special nutrition, also in tuberculous, anæmia, gastritis and convalescence after fevers.

Virol is a nutritive food for invalids and children. It is a preparation composed of Red Marrow, extracted from ox rib and calves bones by C. P. glycerine; refined Marrow Fat; highly diastatic Malt Extract; yolks of new laid Eggs; fresh Lemon Juice and soluble Phosphates.

*In glass jars: 50c, \$1.00
and \$2.00.*

Liberal samples and interesting literature sent to physicians on request.

IT is a pleasure to announce that VIROL is again available. Many physicians who formerly prescribed this valued nutrient learned with regret over two years ago that no further supply could be obtained in this country.

War conditions reduced the production, while at the same time increasing the demand for Virol. Early in 1917 the British government decided to conserve the limited supply for the use of their hospitals and the many thousands of children dependent upon Virol. Exportation was therefore prohibited.

The embargo has now been raised and Virol will be placed on sale as rapidly as possible. The formula which gained the approval of so many physicians in the past remains unchanged.

in aeronautics and aviation, physiology of aviation, the injuries and destructive effects of aeroplane bombs, and aeroplane arrows, also aeroplane dope poisoning. There are many photographs of aeroplane accidents that help sustain interest in this book.

VENEREAL DISEASES. A Practical Handbook for Students. By C. H. Browning, M.D., Director of the Bland-Sutton Institute of Pathology of the Middlesex Hospital; and David Watson, M.B., C.M., lecturer on venereal diseases, Glasgow University; surgeon in charge of the Venereal Department, Glasgow Royal Infirmary.*

As one of the deplorable sequelae of the war we must expect an unavoidable increase in the number of men suffering from venereal diseases. It is safe to assume that within the next few years an increasing number of physicians will seek reliable information concerning the pathology and therapy of gonorrhea and syphilis, and their relation to other diseases. While nothing entirely new has been produced as the result of extensive war experience to be offered in this volume, the appearance of a new contribution in the field in itself is noteworthy if it presents available information in a more suitable manner. Such seems true for the short handbook before us. All the essentials of these diseases are discussed clearly and specifically from the viewpoint of practical application. There are many splendid illustrations and color plates that of necessity will prove most valuable.

In an introduction to the book Sir John Bland-Sutton compares the volume in its usefulness for students and practitioners to the Nautical Almanac for mariners. This comparison is well justified.

SURGICAL ASPECTS OF TYPHOID AND PARATYPOHID FEVERS. Founded by the Hunterian Lecture for 1917, Amplified and Revised. By A. E. Webb Johnson, D.S.O., M.B., Ch.B. (Vic.), F.R.C.S. (Eng.); Temporary Colonel, Army Medical Service; consulting surgeon, British Expeditionary Force, France. Hunterian professor of surgery, Royal College of Surgeons of England; assistant surgeon to the Middlesex Hospital. With foreword by Lieut. General T. H. Goodwin, C.B., C.M.G., D.S.O., Director General, Army Medical Service.†

W. W. Keene in 1898 published a book on the surgical complications and sequels of typhoid fever which has been known as a standard authority on the subject. The author recognizes this fact and proceeds to present additional information that has been obtained on the subject subsequent to the publication of Professor Keene's book. Forty-one pages are devoted to history and the publishing of ancient photographs. The student of the surgery of typhoid and paratyphoid will gain nothing of practical value by studying this part of the book.

The increased number of fever cases which must occur in trench warfare has given the author an exceptional opportunity for study of this subject. The "carrier" problem is one of immense interest and importance, not only to the army but also to the civil community and the views regarding this and the role played by the spleen are ably set forward. Complications involving different organs, tracts, and systems are discussed adequately, in this book, and the surgical treatment of these complications taken up in detail.

PRESERVING THE TEETH

ANATURAL flow of saliva is essential to preservation of the teeth. It works in and out between the teeth, dissolving the food particles, neutralizing unfavorable mouth acids, checking the destructive action of germs, and breaking down protein plaques, tartar and other harmful deposits about the teeth and gums.

The use of chewing gum promotes a free flow of normal, slightly alkaline saliva, and thus may become a very important factor in the preservation of the teeth.

Aside from stimulating the secretion of saliva, chewing gum is exceedingly effective as a mechanical cleansing agent. Thus it acts as a mouth wash and tooth brush combined.

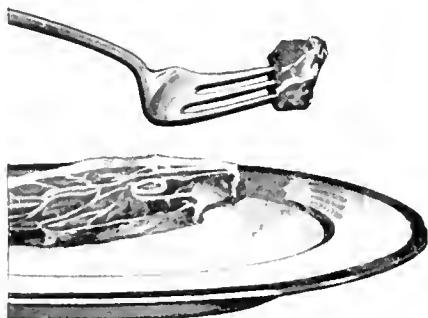

Physicians can safely recommend Adams Pure Chewing Gum to aid in the preservation of the teeth, because it is made of the purest of chicle and for many years has been the favorite gum of fastidious people.

Medical Chautauqua at Dayton

A medical chautauqua was held recently at Dayton, O. It was conducted much the same as an ordinary Chautauqua except that it was purely for instruction and not for entertainment. Specialists of national reputation discussed subjects on which they were experts.

MODEL ORDINANCES FOR THE SUPPRESSION OF VENEREAL DISEASES

The United States Public Health Service has prepared and issued a number of model ordinances which have been adjudicated and have proved successful in combatting venereal diseases. Among the ordinances in compilation are: General Venereal Disease Control Ordinance; Hotel and Rooming House Licensing Ordinance; an Ordinance Regulating Public Vehicles; an Ordinance Regulating Public Dance Halls; the "Tin Plate" Law; an Ordinance Prohibiting Advertisement of Venereal Disease Nostrums; the Restaurant and Grill Booth Ordinance; Ordinance Prohibiting the Sale of Venereal Disease Medicines Except on Prescription; Massage Parlor Ordinance; and additional ordinances in various states relating to the protection of the public against venereally infected persons.

LABRADOR TO HAVE HEALTH CENTER

A Health Center is to be established in Labrador this winter by the Young Women's Christian Association which will be similar to those it has established in New York and to those which it hopes soon to have in operation in other of the large cities of the United States. The work will be under the direction of the Social Morality Committee of the Association.

Dr. Vivia Belle Appleton of San Francisco, has just returned from France where she established what she terms a "Well Babies Clinic" under the American Red Cross, and is to take charge of the work in Labrador, which is being done in connection with the Grenfell Association. Doctor Appleton will make her rounds in a sledge drawn by a dog team. She is getting together an equipment of supplies including everything from food and physicians' supplies to warm fur coats and a leather sleighing suit.

A NEW GERM FOE OF MAN

An investigation just completed by Surgeon Edward Francis of the United States Public Health Service adds another to the list of disease germs afflicting mankind. The germ which bears the name of *bacterium tularensis*, was first isolated by Doctors McCoy and Chapin, of the United States Public Health Service, as the causative agent in a plague-like disease of rodents. It was not then known that the same germ also infects man.

Doctor Francis now finds that *bacterium tularensis* is the cause of "deer-fly fever" a disease occurring among the rural population of Utah and according to popular belief, initiated by a fly bite on some exposed surface of the body. The site of the bite and the neighboring lymph glands become tender and inflamed, and they commonly suppurate. A fever, like that in ordinary blood poisoning, develops and lasts for three to six weeks. The patient becomes very sick and is confined to bed. The first case known to have ended fatally was reported in 1919.

Thus far something like two dozen cases of this disease have occurred in Millard County, Utah, in each of the years 1917, 1918, and 1919. Whether the disease prevails elsewhere is not yet known.

STERLING

Therapeutic Lamp

"The Light That Heals"

Has proved one of the most efficient methods of relieving pain; its effect is soothing and analgesic; its rays are germicidal. The warm, soothing, soft rays penetrate and vitalize every cell and tissue, new cell growth is stimulated; the body is refreshed and vitalized.

In rheumatism, neuralgia, neuritis, lumbago, in nervous conditions and a score of other symptoms and diseases, including skin and scalp disease, the Sterling Therapeutic Lamp is invaluable for the relief from pain, inflammation and for corrective purposes.

Scientific—Efficient—Economical

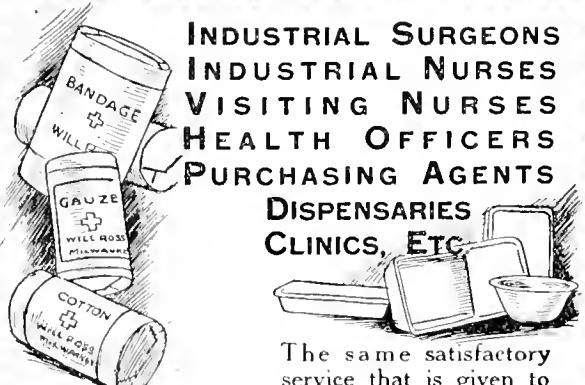

With stand it is ideally adapted for additional use as a spot light for operations and examinations as illustrated. Widely used in sanatoriums, physicians' offices and hospitals; special sizes are adapted for the use of patients under the supervision and direction of the family physician.

Write for our interesting Illustrated Booklet showing the various sizes and uses of the Sterling Therapeutic Lamp.

English Ministry of Health

The English Ministry of Health Act which went into effect July 1, 1919, will be subjected to very close scrutiny by those who feel that strongly centralized health administration, bringing into coordination all the existing health agencies, is the only proper solution for the administration of health functions of a country. The text of the law is printed in *Public Health Reports*, 1919, XXXIV, No. 41.

PLAN RECREATION FOR ARMY NURSES

Eight Social Directors have been placed by the Young Women's Christian Association in the United States army hospital since the first of May, to organize social activities for the nurses serving there.

An army nurse has very little time of her own. To enjoy that time to the full, she must have something to do or some place to go planned in advance. The social director makes those plans for her—arranges hikes, picnics, swims, teas, stunt parties, and dances, as well as all sorts of athletic contests. The Association Hostess House is the recreation center for parties, and a home-like place for reading, writing, and resting.

Miss Beatrice Coe, the Social Director at General Hospital No. 41 at Fox Hills, Staten Island, N. Y., has charge of recreational work for 400 nurses. With them she has enjoyed everything from Coney Island trips to baseball games, from moonlight boat rides up the Hudson to marshmallow roasts and bacon bats nearer home. "I never knew girls could have such fun before!" exclaimed one girl, at the end of a party.

Hostess Houses are entertaining 1,000 army nurses a week in New York City alone, and twelve hundred nurses and aides are served by the Young Women's Christian Association in camps near the city.

HEALTH OFFICERS AND PHYSICIANS OPEN COUNTY HEALTH CENTER

Health officers, physicians, and welfare organizations of Alameda County, Cal., have established a public health center through which an effort will be made to co-ordinate all of the public health activities of the territory.

The Alameda County center is organized under a board of governors, composed of representatives from the hospitals, dispensaries, relief organizations, schools, civic bodies, welfare organizations, the health departments, and medical and dental associations. The center is under the direction of a technically trained, medical expert. It reports that 2,000 cases are being cared for each month at temporary headquarters established recently at Health Center No. 1.

The health center has been made the out-patient department of the new County Hospital of Alameda County. A considerable saving of public funds has been made possible in this manner by giving clinical care to patients not sufficiently ill to remain in the hospital.

The center also acts as a clearing house for the Arroyo Sanatorium, this work being carried on through the division of tuberculosis.

The board of supervisors of Alameda County has appropriated \$23,000 for the support of the clinical work during 1919. The executive officers of the center are located in Oakland at 1104 Federal Realty Building.

Attractive and intelligently written pamphlets and bulletins are being distributed to the citizens of the county, to employers, bankers and professional people. The work has received widespread endorsement among citizens and professional people.

Physical Conditioning

So many patients, especially women, lack the initiative to follow general advice regarding exercises, dietary, and personal hygiene. Physicians acquainted with my work are constantly referring these cases to me for physical and mental "conditioning."

A woman can often inspire her sex to be and to do and hold her to this inspiration by regular correspondence as men cannot.

Every pupil's requirements are studied individually, and each is directed according to her needs and her strength.

This cooperative work with the medical profession is giving results highly gratifying to both physicians and patients.

I shall be glad to assist you with patients who need conditioning through exercise, diet, breathing, correct poise, relaxation, reduction of flesh, or building of flesh.

Susanna Cocroft
624 Michigan Boulevard Chicago

A MILLION WOMEN HEAR HEALTH LECTURES OF Y. W. C. A.

During the period between March 1 and July 1, 1919, the Social Morality Committee of the Young Women's Christian Association has given 1,870 lectures in twenty-two states of the Union with audiences totalling 189,950. During the month of June 1,068 lectures were given in thirty-six communities in twelve states with an attendance of 89,828. The total attendance at lectures given on questions of social, mental and physical health to women and girls throughout the United States since the organization of the Y. W. C. A. War Work Council in June, 1917, is 1,363,570.

THE SURVEY

In the issue of *The Survey* under date of Oct. 4, 1919, is an interesting comparison of "The Two General Strikes in Retrospect, Winnipeg and Seattle," by Edward T. Devine. In both strikes the objectives were of the ordinary kind, but in both cases there was added to the orthodox craft unionism the "one big union" idea, and in both cities the difficulties were exaggerated by the irrepressible and instinctive response to rallying class cries. In each case the strike failed to gain its objective, but in each case the strength of organized labor was demonstrated and the men seem reasonably content with their defeat. All sides of the question are set out in this article with extreme fairness. Ample evidence of discontent under existing conditions are disclosed by this study and "very positive proof of the capacity of men of English speech to misunderstand and misjudge one another." He found no evidence of "seditious conspiracy, of treason, of bolshevism, or of revolution."

The same number contains an article on "The Parliament of Labor" by Arthur Gleason. In the stand taken by the Labor Party for the nationalization of the mines, he sees history in the making in England which is as significant as the Russian Revolution. The British worker reserves his right for dissent or protest and wishes his revolution to come gradually as an organic change.

ESTABLISH PUBLIC HEALTH LABORATORY

A cooperative public health laboratory will be established and maintained at the University of New Mexico, at Santa Fe, as the result of an agreement between the State Department of Health and the University.

The purpose of the laboratory is to furnish scientific bacteriological tests necessary for the accurate diagnosis and treatment of certain diseases to the hundreds who are unable to pay and to physicians who do not have access to such facilities elsewhere.

Under proper conditions and without cost to the public the laboratory will be available for Widal tests for typhoid, diphtheria and Wassermann tests, examination of sputum, tests for rabies, bacteriology of water and milk, all tests to be made by means of specimens sent in by physicians. The only persons permitted to make personal visits to the laboratory will be those taking treatment for rabies.

The State Commission of Hygiene has recently been established at the University in cooperation with the Federal authorities. Prof. A. O. Weese, of the biological department, will be acting director of the Department of Hygiene at the University for the coming year. The work of this department will include physical education for both men and women concerning which important announcements will be made.

PURE, POTENT AND PRACTICAL

Neosalvarsan

Trade Mark Reg'd U.S. Pat. Off.

(NEOARSPHENAMINE-METZ)

Is as pure and potent as the imported product.

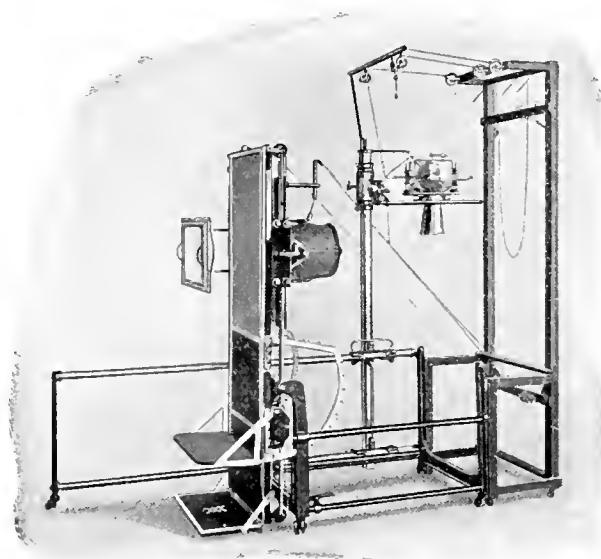

NEOSALVARSAN immediately dissolves in room-temperature water, (68°-77°F) and can be injected by means of a 20 to 50 c. c. glass syringe.

WHEN PROPERLY ADMINISTERED, NEOSALVARSAN does not cause reactions.

"**DEALERS DIRECT WITH YOU"**

THREE NEW HEALTH JOURNALS

Three new health magazines have made their appearance in the last two months. The *Health Prospector*, published by the Arizona Anti-Tuberculosis Association, presents in its initial issue an account of the public health campaign waged by the state organization. The Indiana Tuberculosis Association is sponsor for the *Hoosier Health Herald* which contains in its first issue a goodly number of articles dealing with the public health progress in Indiana. The *Health Round-up* is the name of the monthly organ published by the Texas Public Health Association. The first issue under date of October 1 gives the results of the national Modern Health Crusade Tournament; also an outline of the plans for the coming Red Cross seal campaign. All three of these organs will be a great help in enlisting the interest of the enlightened citizenship of the states in the health conservation drive.

WAR BENEFITED ENGLISH WOMEN

Women in England are better physically and mentally than they have ever been, according to Dr. Christine Muriell, of London. Being forced into industry by the war has resulted in their having more money than ever before, which means three square meals a day. With a mother who eats properly and sleeps well, the next generation will start out with a better chance than any previous generation. In regard to the lowered birth-rate, she says that she does not consider this an unmitigated evil because housing conditions are so bad that there is not room for what people there are. The question of venereal disease which has increased alarmingly is being solved by means of free clinics. All confidences are kept inviolate and all names absolutely secret which results in more patients presenting themselves for treatment. An educational campaign relating to sex and family life is being undertaken.

THE EFFECT ON HEALTH

In New York City, the Bureau of Preventable Diseases, under the direction of Dr. Louis I. Harris, recently conducted an investigation of over two thousand families visited because of tuberculosis or diphtheria or scarlet fever to determine what part the rising cost of living played in their economic status. It was found that over one-half had family incomes of less than \$900, and 21 per cent less than \$600. In more than 37 per cent of the families, meat was entirely eliminated from the dietary; even more of them did without eggs; nearly one-third used no butter. Children were found to be the chief sufferers, a large proportion of the parents being unable to buy milk, or being obliged to substitute loose for certified milk. The resulting picture of health conditions is too familiar to *Survey* readers to require reproduction here. One need only add that there is no reason to believe the experience of New York with respect to prices to be very different from that of other cities. In an interview with a representative of the New York World, a few days ago, Governor Smith explained that he had no power under existing laws to regulate or in any way affect the price of milk; in this matter, likewise, the situation in New York is not abnormal. Municipal and state action everywhere, in spite of innumerable investigations and commissions, has failed to check the upward trend of food prices; and practically all who are conversant with the problem now look to the federal government for effective, i. e., drastic action—action which they feel can no longer safely be postponed.

"AMERICAN"

THE PRODUCT OF SPECIALISTS

BUILDINGS versus EQUIPMENT

Bed-Pan Sterilizer and Washer
Dumping Type

The reputation of an institution does not depend so much upon the character of the buildings that house it as upon its PERSONNEL and its WORKING EQUIPMENT.

Beyond a certain point anything that may be added to the exterior becomes an embellishment—beautiful but not VITAL.

Proper sterilizing equipment is vital.

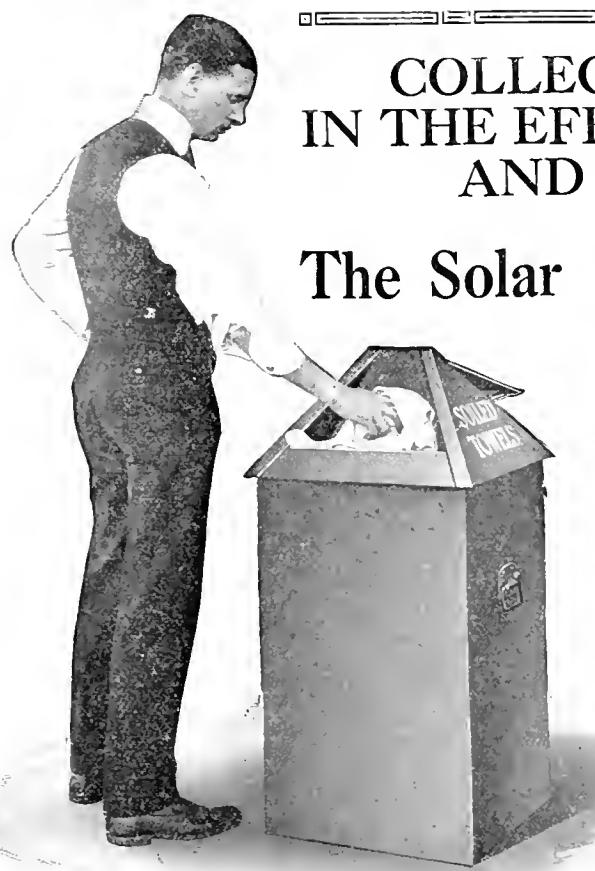

Next in importance to the human element in any undertaking are man's mechanical aids. Doubly so is this true of the Surgeon's work.

"AMERICAN" sterilizers are built to be worthy of this important role. DEPENDABLE, EFFICIENT and EASY OF OPERATION—they have gained the front and have kept it. Investigate "AMERICAN" sterilizers and you will find that the secret of their success is HIGHEST QUALITY and LONGEST SERVICE.

AMERICAN STERILIZER COMPANY, Erie, Pa.

COLLECT SOILED LINENS
IN THE EFFICIENT, ECONOMICAL
AND SANITARY WAY

The Solar Self-closing Waste Can

The inside sack, when filled, is lifted out and replaced with an empty one. The filled sack and contents are carried to the laundry. The collector is always in service—removals are prompt and complete.

Strongly made of steel and attractively finished in oven-baked, durable and cleanly enamel.

Child Hygiene Lectures in China

Candy making demonstrations or a demonstration of how to bathe and properly care for the baby may either be the feature of the day at the “open house” of the Young Women’s Christian Association in Foochow, China. If the latter, it is given by a nurse from a near by hospital who brings a life-size, properly dressed celluloid baby doll with her as an aid to her lecture. Whichever it is, the Chinese women listen eagerly and come again the next week if possible.

SEASONS AND SICKNESS

Seasonal variation in diseases was discussed in the September issue of MODERN MEDICINE by Chas V. Craster, M.D., as related to the epidemic of the more common contagious diseases in Newark, N. J., with the conclusion that it was an important factor in the cases studied. In the October issue of the *American Journal of Public Health* Dr. W. A. Evans tabulates the bacterial maladies in Chicago since 1871, studying them from another angle, that of a comparison of increasing or decreasing mortality. His conclusions are significant, and he declares that all factors tending to an increased resistance should be searched out in order to discover and foster all the principles controlling immunity.

A BAN ON CORSETS AND HIGH HEELS

Corsets and high heel shoes are doomed. The edict went forth from the International Conference of Women Physicians which was held at New York. There is no place for either in the latest scheme for improving the modern woman physically. Representatives of a number of foreign countries participated in the heated discussion which preceded the vote. The abolition of the corset carries with it the skirt band, for everything must hang from the shoulders. A tight skirt band on an uncorseted figure can do more harm than a corset. The proper shoe, the physicians are agreed, must have a flexible arch, low flat heel, and a straight inner line with a broad toe. Even bedroom slipper heels should be abolished. A dress display included one which might be made to serve for both marketing and for the opera, the changes being effected by means of different colored under and over tunics.

FOOT BINDING NOT OBSOLETE

“No other country except China has set itself up seriously as a rival to America in the business of mutilating women’s feet, and China has reformed,” says a correspondent in the *New York Times* in reporting efforts of the Young Women’s Christian Association to promote the use of a shoe which fits the normal foot. By the use of the high heeled, narrow toed shoes so commonly worn by American women, a strain is put upon the spine, the internal organs are drawn out of place, and the foot is tilted to the angle of a horse’s hoof. The type of shoe habitually worn by American women has been the object of the amazed interest of the foreign physicians attending the International Conference of Women Physicians in New York. Physical examination before the Congress demonstrated the inability of eliciting even a wiggle from toes deformed by such shoes. The association has adopted a standard shoe with straight line on the inside of the foot and a flexible sole, so that the toes that were intended to grip the ground when walking may have a chance to perform their natural function. They have listed the retail shoe stores all over the country and in Canada where the approved shoes can be bought. It remains to induce women to wear them.

Cafeterias and Lunch Rooms Are Common Sense Health Insurance

The physical and mental well-being of employees are important factors in the efficiency of every industry. Faulty nutrition is recognized as a detrimental condition for the satisfactory progress of school children, as well as preventing 100 per cent service from the employee. Properly conducted Cafeterias have proved their worth in bringing the individual up to par in both industries and schools.

Rest and Club Rooms, considered essential by many employers, add that element of good-will necessary for the complete co-operation of the employee.

As the largest Cafeteria and Lunch Room Equipment house, we are prepared to design a Cafeteria or Lunch Room to meet any special needs, or to advise on correct equipment and installation. Regardless of what is required, we can supply it—at a saving. We furnish everything for Rest Rooms or Industrial Clubs at a saving to you of time and money.

Successful installations all over the country testify to our ability in these lines. Let us assist you in the formulation of your plans.

CONFERENCE OF ILLINOIS CHARITIES

An explanation of the Red Cross peace time program was given by Walter F. Davidson, director of Civilian Relief for the Red Cross, of Chicago, before State Conference of Charities and Corrections held at Decatur, Ill., during the last week of October.

BOOKS RECEIVED

[Comment on current medical and health literature will be found on page 649, in the department, "Books of the Month."]

DYNAMIC EVOLUTION. A Study of the Causes of Evolution and Degeneracy. By Casper L. Redfield. Cloth, 8vo, pp. 210, \$1.50. G. P. Putnam's Sons, New York, 1914.

THOUGHTS OF A PSYCHIATRIST ON THE WAR AND AFTER. By William A. White, M.D., Supt. of St. Elizabeth's Hospital, Washington, D.C.; Professor of Nervous and Mental Diseases, Georgetown University, Professor of Nervous and Mental Diseases, George Washington University. Cloth, 8vo, pp. 137, \$1.75. Paul B. Hoeber, New York, 1919.

THE ANATOMY OF THE PERIPHERAL NERVES. By A. Melville Paterson, M.D., F.R.C.S., Lieut.-Col. R.A. M.C., Assistant Inspector of Special Military Surgical Hospitals, Professor of Anatomy in the University of Liverpool, Examiner in Anatomy at the Royal College of Surgeons, of England, etc. Cloth, 8vo, pp. 165, illustrated. Oxford Medical Publications, New York City.

DISEASES OF THE STOMACH, INTESTINES AND PANCREAS. By Robert Coleman Kemp, M.D., professor of gastro-intestinal diseases at the Fordham University Medical School; gastro-enterologist at the Fordham University Clinic; consulting physician and gastro-enterologist to the Manhattan State Hospital. Cloth, 8vo, third edition, revised, pp. 1,096, illustrated, \$7. W. B. Saunders Company, Philadelphia, 1917.

THE ITINERARY OF A BREAKFAST. A Popular Account of the Travels of a Breakfast Through the Food Tube and of the Ten Gates and Several Stations Through Which it Passes, also of the Obstacles Which it Sometimes Meets. By J. H. Kellogg, M.D., medical director of the Battle Creek Sanitarium. Cloth, 8vo, pp. 210, illustrated \$1.60. Funk & Wagnalls Co., New York, 1919.

VENEREAL DISEASES. A Practical Handbook for Students. By C. H. Browning, M.D., D.P.H., director of the Bland-Sutton Institute of Pathology in Middlesex Hospital; and David Watson, M.B., C.M., lecturer on venereal diseases, Glasgow University; surgeon in charge of the venereal department, Glasgow Royal Infirmary, and of the Lock Hospital, Glasgow. With an introduction by Sir John Bland-Sutton, F.R.C.S. Cloth, 12mo., pp. 336, illustrated. Oxford University Press, London, 1919.

PERSONAL HYGIENE AND HOME NURSING. A Practical Text for Girls and Women for Home and School Use. By Louisa C. Lippitt, R.N., assistant professor of corrective exercises, University of Wisconsin; and A. Head, reconstruction aide in physiotherapy, Medical Department, United States Army, formerly instructor National School of Domestic Arts and Sciences, and instructor in the training schools of Garfield Memorial, Providence, Columbia, and other hospitals. Cloth, 12mo., pp. 256, illustrated. World Book Co., Yonkers-on-Hudson, New York, 1919.

INFECTIOIN, IMMUNITY AND SPECIFIC THERAPY. With Special Reference to Immunologic Technic. By John A. Kolmer, M.D., Dr.P.H., M.Sc., assistant professor of experimental pathology, University of Pennsylvania; professor of pathology, University of Pennsylvania; professor of pathology and bacteriology, Philadelphia Polyclinic, and Pathologist to Philadelphia Hospital for Contagious Diseases; with an introduction by Allen J. Smith, M.D., Sc.D., LL.D., professor of pathology, University of Pennsylvania. Cloth, 8vo, second edition, revised, pp. 978, illustrated, \$7.50. W. B. Saunders Company, Philadelphia, 1917.

Stanolind Surgical Wax

Reg. U. S. Pat. Off.

A new dressing for burns, granulations and similar lesions.

Manufactured by the Standard Oil Company of Indiana, and guaranteed by them to be free from deleterious matters, and so packed as to insure it against all contamination.

Stanolind Surgical Wax has a sufficiently low melting point so that when fluid the possibility of burning healthy tissue is precluded.

Its correct ductile and plastic features make it adaptable to surface irregularities without breaking.

When properly applied it adheres closely to sound skin, yet separates readily and without pain from denuded surfaces.

Stanolind Surgical Wax when applied in proper thickness maintains a uniform temperature, promoting rapid cell growth, and assisting nature to make repairs quickly.

Stanolind Petrolatum

A New, Highly Refined Product

Vastly superior in color to any other petrolatum heretofore offered.

The Standard Oil Company of Indiana guarantees, without qualification, that no purer, no finer, no more carefully prepared petrolatum can be made.

Stanolind Petrolatum is manufactured in five grades, differing one from the other in color only.

Each color, however, has a definite and fixed place in the requirements

of the medical profession.

"Superla White" Stanolind Petrolatum.

"Ivory White" Stanolind Petrolatum.

"Onyx" Stanolind Petrolatum.

"Topaz" Stanolind Petrolatum.

"Amber" Stanolind Petrolatum.

The Standard Oil Company, because of its comprehensive facilities, is enabled to sell Stanolind Petrolatum at unusually low prices.

An appropriation of \$23,000 for the budget of the health center has been asked of the Oakland, Cal., Board of Supervisors. Of this amount, \$9,000 will be used for clinic purposes, \$8,000 for the study and prevention of tuberculosis, and the remainder for the salaries of the secretary and director and for running expenses. Bids have been asked for the reconstruction of the old county hospital at San Leandro.

STATEMENT OF THE OWNERSHIP, MANAGEMENT, CIRCULATION, ETC., REQUIRED BY THE ACT OF CONGRESS OF AUGUST 24, 1912,

Of *Modern Medicine*, published monthly at Chicago, Ill., for October 1, 1919.
State of Illinois {ss.
County of Cook }ss.

Before me, a Notary Public in and for the State and county aforesaid, personally appeared H. T. McClure, who, having been duly sworn according to law, deposes and says that he is the Secretary of the Modern Hospital Publishing Co., Inc., and that the following is, to the best of his knowledge and belief, a true statement of the ownership, management (and if a daily paper, the circulation), etc., of the aforesaid publication for the date shown in the above caption, required by the Act of August 24, 1912, embodied in section 443, Postal Laws and Regulations, printed on the reverse of this form, to wit:

1. That the names and addresses of the publisher, editor, managing editor and business managers are:

Publisher: The Modern Hospital Publishing Co., Inc., Chicago, Ill.

Editors: Alexander Lambert, M. D., New York, N. Y.
S. S. Goldwater, M. D., New York, N. Y.
Otto P. Geier, M. D., Cincinnati, O.
C-E. A. Winslow, Dr. P. H., New Haven, Conn.
Walter H. Hamburger, M. D., Chicago, Ill.

Managing Editor: John A. Lapp, LL.D., Chicago, Ill.
Business Manager: Dr. O. F. Ball, Chicago, Ill.

2. That the owners are: (Give names and addresses of individual owners, or if a corporation, give its name and the names and addresses of stockholders owning or holding 1 per cent or more of the total amount of stock.)

O. F. Ball, Chicago, Ill.; Frank M. Bailey, Chicago, Ill.; A. F. Nagle, Jr., New York, N. Y.; R. S. Gronemann, Chicago, Ill.; I. V. Barth, St. Louis, Mo.; Mrs. L. M. Ball, St. Louis, Mo.; H. T. McClure, Chicago, Ill.; C. S. Mott, Chicago, Ill.

3. That the known bondholders, mortgagees, and other security holders owning or holding 1 per cent or more of total amount of bonds, mortgages, or other securities are: (If there are none, so state.) There are no bondholders, mortgagees, or other security holders.

4. That the two paragraphs next above, giving the names of the owners, stockholders, and security holders, if any, contain not only the list of stockholders and security holders as they appear upon the books of the company but also, in cases where the stockholder or security holder appears upon the books of the company as trustee or in any other fiduciary relation, the name of the person or corporation for whom such trustee is acting, is given; also that the said two paragraphs contain statements embracing affiant's full knowledge and belief as to the circumstances and conditions under which stockholders and security holders who do not appear upon the books of the company as trustees, hold stock and securities in a capacity other than that of a bona fide owner; and this affiant has no reason to believe that any other person, association, or corporation has any interest direct or indirect in the said stock, bonds, or other securities than as so stated by him.

H. T. McCLURE,
Secretary.

Sworn to and subscribed before me this 30th day of September, 1919.

NOTES AND COMMENT

THE AMERICAN PUBLIC HEALTH ASSOCIATION

THE presidential address of Lee K. Frankel, retiring president of the American Public Health Association, delivered at the opening of the forty-seventh annual meeting of that organization held at New Orleans, is an index to the thought, affairs, and hopes of that splendid body of men who represent the public everywhere in the capacities of health officers, medical directors, or leaders of health organizations.

The three tendencies of the times in the field of American Public Health are defined by Doctor Frankel. These he names as the active entrance of the American Red Cross into the public health campaign, the movement for compulsory sickness insurance, and a demand for coordination and extension of Federal health activities.

His comment upon the work of the Red Cross places emphasis upon the great possibilities of the movement for public health nursing service and the health center movement. Hand in hand with these enterprises, there must be promoted a progressive spirit of cooperation between all the national, local, and legally constituted health authorities whose work leads toward the common goal. The first of these functions clearly belongs to the regularly constituted health authorities and there seems some tendency for the second to pass into their hands in connection with certain diseases. He therefore recommended that the interrelationships between these sanitary and medical functions and the direct economic problem of sickness insurance should be studied by a special standing committee of the Association.

Dr. C.-E. A. Winslow, contributing editor of

MODERN MEDICINE, has given an account of the meeting held at New Orleans which will be found on page 663. The substance of the thought and discussions in the sectional meetings of the Association offers genuine inspiration to the American medical profession and allied professions.

NATIONAL PHYSICAL EDUCATION SERVICE

THE Playground and Recreation Association of America, at the request of the National Committee on Physical Education, has established a national physical education service, with the aim of disseminating, through the various states, the best thought of leaders in this field; of stimulating the necessary state legislation for compulsory physical education; and of rendering every possible assistance to the states in planning and securing such legislation. Seven states have already enacted such laws within the last two years, New York, New Jersey, Nevada, Rhode Island, California, Maryland, and Delaware, and in many other states the matter has been brought up before the legislatures.

Is America as a whole going to answer the call of this progressive movement? Are our rural districts going to realize the necessity of physical education with its broad program of instruction in health principles, periodic physical examinations, and direction in vigorous recreational activities? Are we as a Nation going to keep step with England and France,—for they both are reorganizing their educational systems to include physical training and athletics? Only as we enter into the movement for national physical fitness

concretely and as a people, shall we be able to enter with full stride upon the new era of economic and spiritual development now before us.

PLASMODIUM AND ANOPHELINE AN UNHOLY ALLIANCE

THIE decadence of Hellenic civilization and the fall of the Roman Empire were caused, not by the Macedonian conquest or the irruption of barbaric hordes, but by the mosquito. This is the conclusion drawn by Jones¹ and others who have subjected both cases to scrupulous investigation, and it is a conclusion from which there appears to be no escape.

The Macedonian conquest would have been inadequate to destroy the Greek civilization, and the irruption of the barbarians into the Roman Empire would not have occurred if the ground had not been prepared, in each case, by a sapping of the resistance of the people by generations of malarial infection.

For an examination of the data relating to the source of the original infection and to the gradual spreading of malaria, our readers are referred to the fascinating work named in the footnote. Our task is to draw practical lessons of present application. The most obvious of these lessons has already been learned in part: that is, that it behooves us to arrest the progress of the identical enemy which caused the downfall of Rome, and to oust him from his strongholds. We must undo, in short, a part of the work of destruction and restore prosperity to great areas of fertile country depopulated by the alliance of anopheline and plasmodium.

The lesson has been most thoroughly taken to heart in tropical and sub-tropical regions, where Caucasians from non-malarial countries have come into contact with the destructive and degenerative effect of malarial infection. Next in order are such districts as the lower Mississippi Valley, where the exigencies of increased production and the growing recognition of the economic losses entailed by neglect of malaria have combined with the general awakening of the public conscience in health matters to set in motion, first experimentation with, and then wide application of measures for malaria control.

The demonstrated efficiency of these measures and the economic gains resulting from their application render certain their generalization at an early date throughout the malarial districts of this country.

The tropical and sub-tropical countries and the

United States may, therefore, be safely considered as well on their way to freedom from malaria, with more or less speed; but the countries referred to in the commencement of this article, regions formerly the home of the brilliant Greek and the solid Roman civilizations, are equally capable of regeneration. In Italy this work has already been seriously commenced, while in Greece proper much has been done. It may therefore be assumed that the swamps of Macedonia, due largely to deforestation, will be taken in hand.

In Asia Minor great valleys lie in the grip of paludism. There is here an opportunity for a great work, at once philanthropic and profitable. Nor is the task a difficult one. Much of the country has now a sufficient population for cultivation on American principles, that is, looking to increase of productivity per man rather than per acre. This population is at present obliged to live in villages, in sites selected for their elevation and, therefore, far from the best land, because during the malarial season it is impracticable to spend the night in the low fertile valleys. Moreover, the improvement of conditions would attract desirable peasants from other less productive but now healthier regions. No better contribution could be made to the vexed questions of the near East than the amelioration of the cultivable area of Asia Minor.

CANCER CONTROL

THE wide publicity accorded by the lay press to Dr. W. J. Mayo's address to the American College of Surgeons will inevitably quicken the general interest in cancer control. In these circumstances it is appropriate to review the history and achievements of the American Society for the Control of Cancer.

This Society was established, rather more than six years ago, in consequence of action taken by the American Gynecological Society. The members of the latter body had been impressed by the fact that an overwhelming majority of women with cancer of the pelvic organs presented themselves for treatment only when the disease was so advanced that, at most, palliative measures were available. A committee appointed to consider how this evil of delay might be combatted, reported in 1913, at the triennial Congress of American Physicians and Surgeons, in favor of setting up of one organization for an educational campaign against cancer. Five laymen guaranteed the expenses for one year, making it a condition precedent that the undertaking should be approved by the medical profession.

The Society was formally founded in New York

¹. Jones, W. H. S.: Malaria a Neglected Factor in the History of Greece and Rome.

in May, 1913, at a meeting of delegates appointed by the principal medical societies of the United States associated with a number of lay citizens. Its functions were stated to be: "to disseminate knowledge concerning the symptoms, diagnosis, treatment, and prevention of cancer; to investigate the conditions under which cancer is found; and to compile statistics in regard thereto."

Mr. Curtis Lakeman was appointed executive secretary; the success of the movement and the prestige now enjoyed by the Society, both with the profession and with the laity, are largely due to his initiative and ability.

While the program of the Society's campaign includes the investigation of "the conditions under which cancer is found," its functions do not overlap those of the older American Association for Cancer Research, many of whose members are also active in the educational work of the younger body.

The working methods of the Society are those of an active liaison agency and of a clearing house. It cooperates with all forces and agencies, local and general, lay and professional, political and administrative, which can assist or be assisted in the education of the public and in the collection of reliable statistical data. Among the collaborators which deserve especial mention are the American Medical Association, acting through its Council of Health and Public Instruction, and the great insurance companies.

As an example of the Society's methods may be instanced the fifty-six-page pamphlet, "What We Know About Cancer," addressed to the medical profession, prepared by a special committee of the Society and published in cooperation with the Council of Health and Public Instruction. Six thousand copies of this pamphlet have been bought by the Massachusetts State Board of Health for distribution. The Society has published, or assisted in the preparation of a number of other pamphlets, leaflets, and posters addressed to the general public. It had, for instance, a share in the preparation of the leaflet, "Cancer; Facts Which Every Adult Should Know," issued by the United States Public Health Service, of which 250,000 will be distributed before the end of the year.

At a time when cancer seems on the increase and when the expectation of life after forty is diminishing, the beneficent work of this Society is of cardinal importance. We must preserve our adults in their ripe years, and the prevention of avoidable cancer is one of the most obvious means. It is to be hoped that the Society, which is on the point of losing its able first executive secretary, Mr. Lakeman, who is joining the League of Na-

tional Red Cross Societies at Geneva, will continue to receive the moral and financial support and assistance not only of the medical profession but of all who are interested in the Nation's health.

THE BRITISH MINISTRY OF HEALTH

BEFORE the passage of the Ministry of Health Act public health matters were cared for, in England and Wales, by twenty-one central and more than two thousand local authorities. The activities of the former group have now been consolidated under the Ministry of Health, leaving the reorganization of local public health work to later legislation. This is in accordance with British parliamentary tradition which is opposed to the sudden introduction of sweeping reforms. In the same spirit, no sensible change has been made in the substantive laws relative to public health.

Under the new law the Local Government Board and the National Insurance Commissioners disappear. As some of the functions of the former were not directly related to public health, powers have been provided for the shedding of such foreign matters when experience has shown how they may best be allotted elsewhere.

The urge toward the creation of the new ministry came from many quarters. The appreciation by the people at large of the importance of preventive medicine, brought home to them by war experience, was of great effectiveness in providing power. But the directive force came from the medical profession which, erstwhile a bitter opponent of health insurance, is now so convinced of its value to the nation and to itself that it is anxious to secure the widest applications of the principles it embodies. Fortunately, the profession was unusually well represented in the present House of Commons, notably by Lister's assistant and successor, Watson Cheyne, and by Christopher Addison, the minister in charge of this bill.

While the details of the law interest us but little, dealing as they do with a situation and a state of mind peculiarly British, there are some points in the history of the Act and in the general principles involved which have a bearing on our own problems.

Practically every organized body of the medical profession in Great Britain was consulted,—and there surely is a plenty of them,—academic, license-giving, governing, and political. Most of them occupied themselves seriously with the problem. This was particularly the case with the British Medical Association, the Royal Colleges, and the bodies that naturally rally round them,

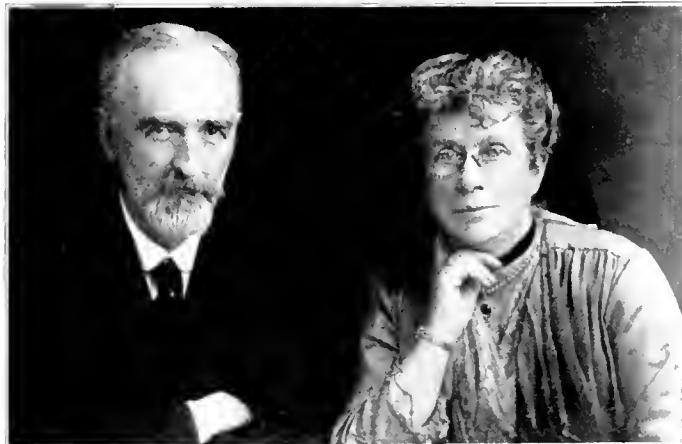

and the General Medical Council. The result was that, when the bill came to the House, it passed through the committee stages in record time and reached the statute book with surprising and gratifying speed. Such modifications of the original draft as were made in the bill were introduced to bring it more into line with the views of the medical profession as expressed by their representative bodies.

Here was a law of first importance to the medical profession and it was the official opinion of that profession which weighed with the legislature. This goes far towards consecrating a principle expressed by one of the representative bodies in the following resolution:

"That any system of national health legislation which does not secure for medical practitioners similar freedom from lay control to that enjoyed by the clergy of the Established Church, by the legal professions, and by the dual profession of arms, must be injurious to the status, prestige, and general well being of the medical profession and hurtful to the best interests of scientific medicine."

At all times there has been complaint that government departments have taken far-reaching decisions on highly technical matters without due consultation of competent advisers, or with an injudicious choice of advisers. This is an evil by no means peculiar to the United Kingdom. Protests from the professions have been made from time to time without satisfactory results. But some of the stupendous blunders of the war having been clearly laid to the charge of this practice; the public conscience has been awakened and the result is seen in one of the most important

FAVORS NATIONAL HEALTH PROGRAM

Sir Arthur and Lady Newsholme. Sir Arthur has given his indorsement of progressive public health measures.

THE national health program which the Red Cross is seeking to inaugurate as an important feature in its peace time activities has the indorsement of Sir Arthur Newsholme, English peer and physician. Lord Newsholme is examiner in state medicine of the University of London and Oxford and a member of the Interdepartment Committee of British Hospitals and his influence will be a powerful factor back of the movement. He says: "Advances in public health in many directions can only be secured by continued and extended medical research in public health, and public health, therefore, has a direct and immediate interest in promoting and subsidizing such research." The primary function of public health, he says, is concerned with environmental measures calculated to prevent disease, whether pre-natal or post-natal.

council. (5) The councils shall have power of initiation, that is, they may address advice to the Minister, not only on matters submitted to them by him, but also *proprio motu*. It shall be obligatory on the Minister to consider such advice. (6) Triennial election is provided for.

The necessity for this effective advisory organization was so strongly felt that much of the discussion in the House turned on means for preventing the law setting it up becoming a dead letter. In the first place, to this end, even the traditional working and rules relating to Orders in Council were modified; secondly, it was proposed that the recommendations of the Councils should be presented to Parliament. The latter proposal was reluctantly withdrawn only on the urgent representations of Addison, who pointed out that the responsibility of the Minister to Parliament would suffice to insure effective action.

In this compromise we see, perhaps, a happy mean between that "government by experts" which those of us who know best most distrust, and that other condition of government by ignorance, prejudice, and accidental interests.

provisions of the new Act. It is laid down that consultative, elective councils shall be established to advise the Minister of Health, and, so that this provision shall be effective, the following rules are enacted: (1) The councils shall be composed without discrimination as to sex of persons of practical experience in the matters on which they are to advise the minister. (2) The members of the councils shall have direct access to the minister. (3) The meetings shall be held regularly. (4) Power is given to appoint sub-committees and to coopt, to these, persons from outside the

THE HISTORICAL DEVELOPMENT OF PUBLIC HEALTH WORK IN ENGLAND

BY ARTHUR NEWSHOLME, M.D., K.C.B., LATE PRINCIPAL MEDICAL OFFICER OF THE LOCAL GOVERNMENT BOARD,
ENGLAND*

THE subject is too large to be treated adequately in the course of an evening's address; and to bring it within manageable compass it is necessary for me to select my material rigidly and, as far as I can, to present this material in such a manner as will bring into relief its salient and most instructive features.

The evolution of public health in England proceeded by experimental steps, some mistaken and then retraced, others mistaken and not retraced, but steps oftenest in the direction of a complete service, which is the goal of our work.

The evolution has been a gradual growth arising out of realized needs, rather than a logical development based on general principles; and as politicians and legislators seldom take a wide outlook, or consider a specific proposal in relation to what is already being done, and to what is the desired goal, the English experience is especially instructive.

Congestion Increases Health Problems

Public health work became an urgent necessity when men began to huddle in towns; and with the industrial revolution of the eighteenth and early nineteenth centuries the need for remedial action became acute. It is hard to realize that in the days of our grandfathers, the home was in most instances the unit of industry; and that in the eighteenth century communications between districts and towns were not more advanced than those of the ancient Egyptians. When, however, vast urban aggregations of population multiplied, traveling facilities rapidly increased, and the results of crowding, of contaminated water supplies, of intensive and widespread infection, were seen in devastating endemic and epidemic diseases. Poverty, squalor, dirt, and their consequences, were rampant in the towns, in which underpaid work-people were exploited by masters,

Public opinion is motive power. Good work cannot for any prolonged period go beyond what the public demands; and the work of officials is one of constant education of their masters and of the public.

Adequate and efficient health administration hinges upon the perennial problem of efficient government. The inveterate tendency in the past has been to create a new authority when any new work was inaugurated.

The first principles of good administration require that when a special function is to be undertaken, it shall be undertaken by one governing body for the whole community needing the service.

whose self-centered outlook had some share of justification in the political economy doctrines of the time which regarded any interference with "freedom of contract" as useless or even pernicious.

What is public health work? It is best defined by stating its object, which is to secure the maximum attainable health of every member of the community, so far as this can be secured by the authorities, local,

state, or federal, concerned in any part of government, acting in cooperation with all voluntary agencies whose work conduces to the same end. The connotation of public health becomes wider year by year. It embraces physiological as well as pathological life; being as much concerned with improving the standard of health of each person as with the prevention and cure of disease. Hence the importance of the "concentration on the mother and her child" (John Burns), to secure for them by all practicable means the conditions of complete health, which during the last twelve years has been a vital part of our public health work, and which is now being made to include not only all hygienic and medical help that may be needed, but also such domestic aid as may enable the mother to bring her children into the world and to rear them under advantageous conditions.

Principles of Constructive Health Work

Public health embraces some eugenic elements, and may comprise more when eugenists have accumulated adequate non-fallacious and unbiased evidence on which to base valid conclusions. Already partial steps are being taken to secure the segregation and prevent the propagation of the feeble-minded and the insane; and in sorting out true heredity from congenital infection action is

*An Address at the Forty-seventh Annual Meeting of the American Public Health Association, New Orleans, October 27, 1919.

being taken to avoid congenital syphilis and to prevent the large number of still-births due to this race poison.

Public health in the main is concerned primarily with the environmental measures calculated to prevent the attack of man by disease, whether pre-natal or post-natal. These measures may be industrial, as in the prevention of accidents, of dust, of noxious vapours; or sanitary, as in the control of water supplies, food, or milk, and in the removal of organic filth; or may be the application of preventive medicine, against infectious and non-infectious diseases; or therapeutic, consisting of the prompt and adequate treatment of all illnesses and the curtailment of the incompetence due to them; or educational, consisting, first in importance, in the training of medical practitioners, of public health officials, and nurses; and, next, in the education of the general public and especially of the children in our schools, in the science and practice of public health.

Advances in public health in many directions can only be secured by continued and extended medical research, and public health, therefore, has a direct and immediate interest in promoting and subsidizing such research.

These being the objects of public health, how far have we travelled toward securing the end in view? I do not propose to myself the pleasant task of showing to what extent the general death rate has been lowered, infant and child mortality greatly reduced, the duration of life extended, how typhus and smallpox have been almost eradicated, typhoid fever made a disappearing disease, and tuberculosis has become the cause of only half its former death rate. When inclined to indulge in such pleasant considerations, I recall the statement I have made elsewhere that one-half of the mortality and disablement still occurring at ages below seventy can be obviated by the application of medical knowledge already within our possession.

Let me attempt the more difficult task of outlining the history of forms of administrative control of disease since 1834.

Reform in the Control of Poverty

Poverty and disease work in a vicious circle in which cause and effect often change places; but it is certain that disease is one of the most fertile causes of poverty, using the word poverty in the sense of privation of one or other essential of physical well being.

For this reason, and because the half starved form a constant social danger, poor-law administration long antedated public health administra-

tion. There is not time to follow the course of earlier poor-law administration, with its many and grievous abuses. The Poor-Law Amendment Act of 1834, gave the Central Government control over the systems of local relief, secured the combination of parishes into unions for poor-law relief¹; and forbade outdoor relief to able-bodied men. The creation of an organ of central control has led to the subsequent course of aid to paupers being determined in the main in London, action of poor-law guardians being subject to supervision by government inspectors, and to endorsement by the Central Authority. At first, medical assistance under the reformed Poor Law was made as deterrent as non-medical relief; and although there has been much improvement, chiefly on the institutional side, medical treatment under the Poor Law has to some extent retained this deterrent element, and it has, excepting in the poor-law infirmaries of large cities, remained generally disliked by the people concerned.

First Central Poor-Law Authority

The first Central Poor-Law Authority was a Commission having no representative in Parliament. In 1847 it was replaced by a Board, the president of which was a member of Parliament and of the Government. Here once for all Parliament declared its intention to maintain direct control of central official government, and in this and in all other departments has done so. If democracy is to be real,—and we have no sound, practicable alternative to it,—evidently the representatives of the people must be masters of the administration; and English policy has never wavered on this point. After many years' experience of public life in England, I have no hesitation in saying that this principle is sound; that it insures progress which, although slow, is less liable to relapse than administration under autonomous expert commissions, whether centrally or locally; and that any lack of progress that has been experienced in central government has been as much the result of inactivity and of lack of sympathy with social reform on the part of the permanent officials of government departments who have had access to their parliamentary chief, as of the inertia of politicians or their obstruction to reform.

Dissatisfaction with Poor-Law administration has steadily increased in the years since 1834, as the problem of the able-bodied pauper has diminished and the Poor Law has been concerned more and more with the sick and infirm, the aged, and children. These at the present time form some

¹ The importance of this is seen in the fact that there are in England and Wales 14,614 parishes, and only 646 unions for the relief of the poor.

98 per cent of the total population relieved. The fundamental principles of the Poor-Law were rightly attacked. It did not comprise elements tending to build up disabled families, or to prevent families from falling hopelessly and permanently into destitution. The law was administered almost entirely with a view to relief; practically not at all as a curative agency. In medical language, symptomatic and not rational causal treatment was the rule.

In medical relief, poor-law administration has been a constant struggle between increasingly humane treatment and the conception that the pauper's position must remain inferior to that of the non-pauper; an important principle when applied to the able bodied adult who has drifted into willing dependence; absolutely mischievous when applied to sick persons, and to dependent women and children.

The general dissatisfaction with poor-law administration led to the appointment of a Royal Commission on the Poor-Laws which, after several years' deliberation, reported in 1909 a majority and minority report. Both these reports recommended the abolition of boards of guardians, and the transfer of their duties to the 144 largest public health authorities in the county (County Councils, 44; and the Councils of county boroughs, 82), and the abolition of the general workhouse. The majority report would have continued the Poor-Law Guardians as a Committee of the new Authority; the minority report proposed to distribute the duties of the guardians to different committees of the Public Health Authority; thus medical treatment to the Public Health Committee, the care of lunacy and the feeble-minded to the Asylum Committee; care of children to the Education Committee; vagrants, etc., to the Police Committee, a special committee concerning itself with all questions of monetary assistance.

De-Centralizing Poor-Law Work

A compromise between these two schemes has recently been arranged, and when the new Ministry of Health, which will combine public health, poor-law, insurance, and educational medical work in one department, has found time to do urgently needed work, the above indicated reform may be hoped for, along with the equally needed reform of local public health administration, and the abolition of a large number of the smaller and less efficient sanitary authorities. With these reforms will come much needed de-centralization of poor-law work. Good work in all respects cannot be secured if the Central Authority concerns itself, as at present, in minutiae of local

administration, and has no time to devote itself to the larger problems, and to the detailed task of bringing indifferent, chiefly smaller authorities, up to the standard of efficient local authorities. A large portion of the expense of local poor-law administration is borne by the central exchequer, and this money if properly applied will give the necessary leverage for reform, while leaving progressive Authorities, and especially the Authorities of large towns, freedom to experiment and advance.

Reform in Industry

The industrial revolution meant the subjection of large masses of working class families to evil conditions of housing and work in crowded and insanitary dwellings and factories. The public conscience first rebelled in regard to boarded out and apprenticed pauper children; and the first Factory Act in 1802 concerned itself with them; and with this Act emerged the germ of machinery for securing compliance with the law, magistrates and clergymen being appointed as inspectors under the Act.

The Act was largely futile; but it meant the beginning of the gradual breaking down of *laissez faire* doctrines; and there followed a more widely operative Factory Act in 1833, restricting hours of labor of children, and initiating professional inspectors controlled and paid by the Government. In 1842 the underground employment of women in mines was forbidden; and there have followed at intervals since then numerous factory and allied acts, restricting the duration and conditions of work of women and children, improving rules as to sanitation, insuring systematic inspection by government inspectors, and constituting a far reaching system of supervision and control.

The inspectors, on whom falls the burden of ensuring compliance with the Factory Laws and regulations made under them, are controlled by the department of the central government known as the Home Office; their work has been well done, and the conditions of factory and workshop life have greatly improved. Some portion of the sanitary supervision of these work-places falls on the local Sanitary Authority; but in the main the system is one of absolutely centralized government control. This secures almost complete absence of improper influence of interested local persons, whether masters or workmen; but it is arguable that this system should be replaced by a localized system, the inspectors being officers of the 144 larger authorities. These local officers could be placed in direct touch with the Home Office or the Ministry of Health and with the cen-

tral staff of inspectors having expert knowledge in the different branches of industrial work.

Public health reform was a direct consequence of the Poor-Law Amendment Act, 1834. Anxious to diminish the enormous expense of the existing Poor Law, and realizing that a large share of this sickness was due to fever and other illnesses, surveys and inquiries were set on foot by the commissioners administering this Act, and the reports which followed revealed a state of things urgently calling for sanitary reform, in the interest of national economy as well as of health. "An Act for Promoting the Public Health" was passed in August, 1848, which created a General Board of Health consisting of four members and a secretary. These Commissioners, among whom was Edwin Chadwick, former Secretary of the Poor Law Board, initiated a system of procedure which was largely on the lines of poor-law action, and which involved constant pin-pricking by the Central Authority of the grossly indifferent local authorities. The commissioners were more zealous than discreet; and after six years they were no longer tolerated. At that time centralization was as much a bogie as socialism has become in more recent years. Parliament and the localities represented by its members doubtless feared the reforming activity of Mr. Chadwick and his colleagues, though they sheltered themselves behind their exaggerated fears of bureaucracy and centralization.

A new board replaced the old, parliamentary in character, its president being a member of the Government. This repeated, so far as concerns Parliamentary headship, the story of the Poor-Law Board, and established once more the theory of the administrative control of the representatives of the people. Nor, although the change meant for the time serious slackening in sanitary reform, can objection be taken to this. In a democratic government the elected representatives of the people must take first place; and it is the rôle of officials to educate them in the direction of needed reforms. Reforms which do not carry public opinion are not likely to be permanently successful; and whether in administration or in legislation attempts to sidetrack or ignore this fact are not likely to be permanently effective.

When the Local Government Board was formed in 1870, a second opportunity was lost of developing Public Health Administration on lines which we now know to be the best adapted for a complete service of preventive medicine. The first lost opportunity was when sanitary authorities completely separate from poor-law authorities, were created for administering the sanitary laws. Probably this arose from Chadwick's despair of

getting effective sanitary reform from poor-law guardians; but the creation of separate authorities was scarcely consistent with the fact recognized by him that pauperism is largely, if not predominantly a question of sickness; and the less recognized fact that its treatment forms an essential part of prevention. It was recognized that the care of the sick was largely idle until the unnecessary causes of disease had been cut off, but not that the adequate treatment of sickness is an important means of preventing it or of curtailing it. Rumsey², in 1856, stated the unrealized possibilities of the poor-law medical officer's domiciliary attendance on paupers in the following words:

There are much higher functions of a preventive nature than those of a mere "public informer" which the district medical officer ought to perform. He should become the sanitary adviser of the poor in their dwellings . . . he (should) be in a peculiar sense, the missionary of health in his own parish or district,—instructing the working classes in personal and domestic hygiene,—and practically proving to the helpless and debased, the disheartened and disaffected, that the State cares for them, a fact of which, until of late, they have seen but little evidence.

In the result the *ad hoc* poor-law authority did not absorb into it the newly created municipal and urban and rural sanitary administration, but continued on its separate path.

Simon, in 1868, had urged the inadvisability of continuance of *ad hoc* authorities, and had urged that, at least, sanitary should be made coterminous in area of administration with poor-law districts. His advice was not adopted, and there followed years in which sanitary authorities were allowed to subdivide areas, until the total number became 1,807 instead of 635, the number of poor-law authorities; and in which they concerned themselves chiefly with nuisances and water supplies and with inadequate provision for the prevention and treatment of infectious diseases. With the creation of county councils and the more complete autonomy of the councils of county boroughs, the large centers of population developed and improved their sanitary administration more rapidly; and it became practicable to undertake every division of sanitary work on an efficient scale. Although much remains to be done, it can be claimed that in our larger towns, containing more than half of the total population of the country, the public health work in nearly all its branches is of a high order. It would have been still more efficient had the poor-law guardians been merged in the Town Council, and the relationship between the school medical service and the other branches of the public health service closer than has been the case.

² Rumsey: Essays in State Medicine, 1856, pp. 190, 277, 282.

What is now needed is that the defects just named should be made good; that more complete autonomy should be given to the authorities which come up to a required standard, and that especially they should have greater freedom in developing local possibilities of improved administration. Central grants in aid of local sanitary administration are steadily increasing. Already the Government pays one-half of local expenditure on a large program of maternity and child welfare work, one-half of the expense of local tuberculosis work, and three-fourths of the expense of local work for the diagnosis and treatment of venereal diseases, and for propaganda work concerning these. These grants should be the means of greatly increasing good local administration, but if,—this is improbable,—they curtail local experimentation and extension, and bring local public health administration into anything approaching the subservience of local poor-law administration, the value of these subventions will be doubtful.

The national system of compulsory elementary education inaugurated in 1870 has had valuable indirect influence in promoting the public health. Apart from the beneficent effect of education, the steadily increasing pressure on children to come to school in a cleanly condition, the stimulus of emulation in tidiness and cleanliness, have done much to improve the home conditions of the people. After the South African war much attention was drawn to the large number of recruits rejected owing to physical disabilities; and an inter-departmental committee reported *inter alia* in favor of a system of medical inspection of pupils in elementary schools, which had often been urged by hygienists. Observations made in Glasgow and Edinburgh by Leslie Mackenzie did much to draw attention to the physical defects in Scottish school children. In 1907 the Board of Education acquired power to make provision through the local education authorities for the medical inspection and treatment of school children. At first little more than inspection of pupils was undertaken, a large number of defects of sight, hearing, parasitic conditions, as well as malnutrition and actual disease being discovered. Gradually some items of treatment were undertaken at school clinics, or at hospitals or centers subsidized by the education authorities; though the amount of treatment is still small compared to the defects discovered and not otherwise treated.

But there now existed in every locality three authorities concerned in the treatment of disease:

1. Poor-law guardians, treating all forms of illness in paupers, at home and in institutions.

2. Public health authorities, undertaking preventive measures against disease, and treating in institutions; and more recently providing nurses at home for certain conditions.

3. Local education authorities, concerned in treating certain ailments in school children.

Centrally two government departments were supervising this work, and subsidizing it to some extent from government funds; and poor-law medical work and public health medical work were supervised by two divisions of the Local Government Board acting in almost complete isolation. More recently Parliament has permitted the Board of Education to give grants in aid of schools for mothers, and allied institutions for the care of children under school age; for which institutions, substantially, the Local Government Board in other instances was giving grants.

The separation of educational medical work from public health medical work was contrary to the first principles of sound administration; although it is possible that, owing to the inertia in some public health circles, this separation at first favored rapid advance in school hygiene; just as the early development of public health apart from poor-law administration was probably more rapid than could have been expected from centrally ridden local authorities, concerned chiefly in keeping down the poor rates.

The Ad Hoc Vice

But in both instances there was an offense against the first principles of good administration, which require that when a special function is to be undertaken it shall be undertaken by one governing body for the whole community needing the service, and not for different sections of the community by several governing bodies. Medical treatment is needed for school children and for the poor generally. Why separate this into two administrations? Hospitals are required for paupers with tuberculosis, and for non-paupers with tuberculosis. Why have two authorities for this work? The separate existence of Education and Poor-Law Authorities qua medical attendance on those needing it erred, not only in this fundamental respect, but also because neither of these authorities has the preventive facilities and powers possessed by Public Health Authorities, who were also partially engaged in the treatment of disease.

The inveterate tendency in the past has been to create a new authority when any new work was inaugurated, this authority then fulfilling all purposes for a special portion of the community and thus necessarily reduplicating the staffs of

other departments of local or central government. The crowning instance of this recurring instance of legislative myopia is seen in the case of the National Insurance Act, under which has been provided an imperfect and unsatisfactory domiciliary medical service for one-third of the entire population of Great Britain, when by combining and extending the medical forces of existing departments of the state, a satisfactory service for all needing it would have been secured. The axiom that "the object of community service is to do away with group competitions and bring in its place group cooperation or team work," (Goodnow), is especially applicable to all public health and medical work; and its spirit is infringed by the existence of separate, sometimes competing, occasionally conflicting, services under separate local and central control.

Principles of Local Government

The preceding considerations bear on the perennial problem of efficient government, local and central. There are three functions to be performed in government, legislation, determination of administrative policy and extent of work, and the actual executive work. In England, legislation is in the hands of Parliament; but large cities not infrequently obtain special legislative power to meet local needs; and by this means have succeeded in advancing local efficiency above the average standard. Local authorities, furthermore, have the power to make regulations and by-laws for special purposes, subject to the approval of the Central Authority.

In settling the details of local administration, the elected representatives of the public are supreme. They meet in Council, and action is taken on a majority vote. The councils of counties and cities, and even of smaller municipal boroughs divide themselves into committees, consisting of about a dozen members, elected by vote of the whole Council. The chairman or mayor of the Council has no special power, except that he may give a casting vote.

The chief defect in local sanitary administration in England is the continued existence of a large number of small and relatively inefficient local authorities. The larger authorities, as a rule, do their work well, and polities enter but little into elections. Official posts are not vacated with changing councils. These councils are approximating to the ideal of a complete local Parliament dealing with all governmental concerns, and to the further ideal that each unit of government should be large enough to minimize the influence of local interested motives, and to undertake each department of municipal work on a con-

siderable scale. The local Parliament has committees concerned with police, finance, public health, education; and when the urgently needed poor-law reforms are made, and when the Education Committee hands over its medical work to the Public Health Committee, the ideal will become a fact.

Power is already given to coopt a few persons on to some of these committees who are not members of the Council, from among men or women having special knowledge of the Committee's work; and the exercise of this power has been found to be useful.

But in each committee it is the direct representatives of the public who decide points of policy and settle the main outlines of administration. There is growing up a tendency to appoint local advisory committees, consisting of special groups representing professional or trade interests. Thus a medical committee may be consulted on medical proposals, and so on. This is still in the experimental stage. It may prove permanently useful, as voicing the occupational aspect of any proposed work of the municipality; but it will need to be kept to its strictly consultative limitations, and the responsibility of the Council as representing the combined wisdom or unwisdom of the entire community must be maintained.

All substitutes for government of the people by the representatives of the whole population are open to objection. They do not contain within them the elements of permanence. If there is a corrupt council, the remedy is not its supersession by an independent executive. Such an executive is the abrogation of popular government. "Good and efficient government is possible under almost any form of organization. More depends upon men than devices . . . But . . . if we believe that the functions of deliberation or determination of municipal policy and of administration or the execution or carrying out of that policy should be kept distinct, we cannot avoid the conclusion that a city council is a necessary part of the municipal organization."³

Each committee of the local Council is advised by the County Clerk or Town Clerk on legal and administrative matters; and the medical officer of health and other expert officers, like the legal adviser, in nearly every instance, hold office during good behavior. Under the above arrangements the elected members and the officials are kept in touch with each other. The latter's recommendations and actual work must be approved by the former; and this works well under the system of determination of policy by committees,

³ Goodnow: *Municipal Problems*, p. 226.

subject to confirmation and control by the entire Council. The motive power is public opinion. Good work cannot for any prolonged period go beyond what the public demand, and the work of officials is one of constant education of their masters and of the public.

The Training and Tenure of Office

Every sanitary district is required to appoint a medical officer of health and since 1888 every medical officer of health for a district with a population exceeding 50,000 must have a special diploma in public health. The enforcement of this requirement has done much to raise the standard of work of these officers. It is significant, furthermore, that while in 1873 the percentage of the total population of England and Wales having whole-time medical officers of health was only 20.6, it has increased to 61.4 per cent in 1911. In the metropolis, in the whole of Scotland, in every English county (forty-four) and in many other districts these officers possess security of tenure, in the sense that they cannot be removed from office without the consent of the Central Government, which usually pays half their salaries. Even without this safeguard, removal from office by the local authority is rare; but there has been long delay in securing the further reform that in all areas the medical officer of health should be able to perform his difficult and sometimes obnoxious duties without fear of removal from office, or of reduction in his emolument, except as the result of deliberate action on appeal to a central authority.

When pensions can be earned by medical officers of health and by all medical men on the public health staff, their position will become more attractive for men of good standing; and this reform has become more important in view of the steadily increasing complexity of the medical work now undertaken in a large public health department. It will include *inter alia* the following officers and activities: superintendent medical officers of health; district medical officers of health; tuberculosis officers; medical officers of maternity and child welfare centers, of venereal disease centers; fever hospitals, and tuberculosis sanatoriums and hospitals.

The development of a graduated public health medical service in which each physician employed will be able to develop his own special abilities, will be easier when to the above list is added the work of district (late Poor-Law) medical officers; medical practitioners attending insured persons and such other persons as are treated at the expense of the State; treatment centers for special conditions of the ear, eye, throat; gynecological

and other special departments; hospital treatment for general diseases.

That there will be development in these directions when the tangle caused by the National Insurance Act of 1911 has been unravelled, there can be no doubt.

I have in another address expressed my opinion as to the additional tangle introduced into the Central and Local Government of the United Kingdom by the National Insurance Act of 1911.

The failure of the British Government to act on the recommendations of the Poor-Law Commission of 1909 was a serious misfortune to public health. Sickness is the cause of a predominant part of our total destitution, and to allow the continued separation of administrative action respecting these two problems is inconsistent with a full measure of success. Political circumstances, however, led to the adoption of a course which, medically, ran directly athwart the course of needed reform.

The National Insurance Act and Public Health

The National Insurance Act was passed, placing one-third of the total population (all employed manual workers and other employed workers with an income below £160, since increased to £250) under an obligation to pay 4d weekly (women 3d), 5d being contributed for each person by the employer (3d) and the State. In return each worker received a money payment weekly during illness, attendance by a doctor, sanatorium treatment for tuberculosis, and a maternity benefit on the birth of a child to his wife (30 shillings) or, if the wife also is industrially employed, an additional 30 shillings. The medical benefit is limited to such domiciliary attendance as a medical practitioner of average ability can furnish. It continues the old conception of private medical practice, and allows the public to remain obsessed with the notion that satisfactory medical care consists in a "visit and a bottle." No provision is made for pathological aids to diagnosis, beyond what is already provided by public health authorities. No nurses are available for serious cases; the insured person is not entitled to surgical operations, when needed, except of the simplest character. With few exceptions, no appliances are provided; the treatment of special diseases of the eye, ear, nose and teeth is commonly excluded. No hospital provision whatever, except for tuberculosis, is made.

The contract system of medical practice has been accompanied by a serious amount of lax certification of sickness. The sanatorium benefit is unnecessary, as soon as the duty of public

authorities to provide treatment for tuberculosis is declared obligatory. It is already very largely provided. The maternity benefit is entirely unconditional; there is no guarantee that it is devoted to the welfare of the mother and infant. It needs to be supplemented or replaced by the arrangement for providing nurses, doctors, midwives, and domestic assistance in process of development by public health authorities. In short, there is no justification for providing medical services, preponderantly at the expense of the state (contributions by employers are a form of taxation), which are limited to a favored portion of the total population, and which do not benefit all in need of these services.

Provision Against Disability

The principle of monetary insurance against sickness and disability is thoroughly sound. It forms a praiseworthy and valuable provision against future contingencies. Insurance, however, is not synonymous with prevention as is too often suggested. In England insurance has been an actual impediment to public health work, though it might have gradually become a useful auxiliary to it if otherwise organized, and especially if the creation of independent insurance committees representing interests to a preponderant extent had been avoided. But any medical service needed for purposes of insurance should not form part of the insurance system. Medical aid is needed for a large section of the population who are unable to afford deductions from their wages, or who have no wages. It is needed for wives and children as much as for the industrially employed head of the household; and it is needed for many others who are excluded from the scope of the National Insurance Act. Only when the medical is separated from the insurance service, and when the medical practitioner, as far as practicable, is made independent of the patient who desires too facile a sick-certificate, will good medical work and sound sickness insurance be secured.

General Summary

The preceding review of the history of public health in England is necessarily fragmentary. It does not include, for instance, a discussion of the relationship of the medical profession to public health authorities. On this I content myself with repeating my oft stated opinion that until every medical practitioner is trained to investigate each case of illness from a preventive as well as from what is often rather a pharmaceutical than a really curative standpoint, until a communal system of consultant and hospital services

independent of any insurance system is made available for all needing it, and until every medical practitioner is related by financial and official ties to this communal system, full control over disease,—to the extent of our present available medical knowledge,—will not be secured.

The communal system will include not only the provision of domiciliary nurses for all needing them, but also a greatly increased staff of public health nurses engaged in educational supervision in connection with the work of the communal services and of each individual practitioner. Such a system will repay the community manifold in improved health and a higher standard of happiness and well being.

If objection is taken to such wide sweeping proposals, let me remind you that free communal services of sanitation and education are already provided; and that the personal care of health is of equal importance with these. All will agree that a large proportion of the population cannot afford to pay individually for medical attendance and nursing under present conditions, still less for the consultant and hospital services which advance in medical service have rendered indispensable. There is always present in our midst a large mass of illness which might have been avoided or curtailed, had there been an organized system of state medicine.

Reducing the Sickness Rate

Lest any should be alarmed as to the possible consequences of the cooperative provision on such a scale of this primary need of humanity, let me remind you that cooperative medical aid differs from financial aid in an essential particular. It does not create a demand for further aid, but is always engaged in diminishing this demand. Dependency on financial assistance is liable to continue indefinitely; much wants more. This result of medical aid is almost inconceivable. The Reverend Doctor Chalmers, of Glasgow, said early in the last century: "Ostensible provision for the relief of poverty creates more poverty. An ostensible provision for the relief of disease does not create more disease."

Doctor Chalmers was opposed to the giving of any domiciliary assistance from rates or taxes, and he organized his parish so that every needy person was adequately helped out of charitable funds. But he advocated extended hospitals and other medical assistance for the poor; and until this is done, apart altogether from any system of insurance, and as a complete measure on the lines of our educational system, we cannot say that all that is practicable has been done to secure the physical well being of our fellow citizens.

THE AMERICAN PUBLIC HEALTH ASSOCIATION

BY C. E. A. WINSLOW, M.D., DEPARTMENTAL EDITOR, MODERN MEDICINE, NEW YORK.

THE American Public Health Association held its forty-seventh annual meeting in New Orleans, October 27 to 30, under the presidency of Dr. L. K. Frankel, of New York. There were more than 1,000 members and guests in attendance and 225 papers and committee reports were on the program of the Association and its various sections. The following officers were elected for 1919-20:

President, Dr. W. S.

Rankin, Raleigh, N. C.; vice-presidents, Dr. A. J. Douglas, Winnipeg, Man.; Dr. S. L. Jepson, Charleston, W. Va.; Dr. W. H. Robin, New Orleans, La.; secretary, A. W. Hedrich, Boston, Mass.; treasurer, Dr. G. H. Sumner, Des Moines, Iowa; new members of the executive committee, Dr. M. P. Ravenel, Columbia, Mo., and Dr. L. K. Frankel, New York City. San Francisco was selected for the place of the 1920 meeting.

A Progressive Association

The address by the president, Doctor Frankel, was delivered on Monday evening and dealt, first of all, with the encouraging growth of the American Public Health Association during the past year to a membership of more than 4,500, and to the satisfactory financial condition of the organization, due to the increase in sustaining and corporate, as well as ordinary, membership. The movement for state public health associations, affiliated with the national society, is making substantial progress and the organization of a National Health Council, made up of delegates from seventeen representative national health societies, promises much for the promotion of cooperative effort among those who approach the public health problem from various special angles.

Doctor Frankel then discussed the three tendencies of the time in the field of American public health, the active entrance of the American Red Cross into the public health campaign, the movement for compulsory sickness insurance, and the demand for a coordination and extension of Federal health activities. In connection with

A dynamic influence arises from the welding together of various public health agencies in a central body. The American Public Health Association is the power plant. Its members, the health officers of states, cities, and towns, and directors of medical and health organizations, and institution heads, generate the power. They have wrought the good that has come with well-functioning health machinery. They have energized ideas. The time is come when new channels are needed to accommodate new burdens and new responsibilities. The expression of this need heard at the New Orleans convention of the Association becomes a summons to health organizations everywhere.

the first of these problems he pointed out the tremendous possibilities of the public health nursing and health center movements initiated by the Red Cross Society and the necessity for close coordination of such efforts with those of the legally constituted health authorities, and recommended the appointment of a special committee of the Association to confer with the Red Cross in regard to its plans. In dealing with the question of

sickness insurance Doctor Frankel pointed out that there are three problems which should be kept distinct: the control of preventable disease, the supplying of adequate medical and nursing care, and the compensation of wage earners for the wage losses caused by illness. The first of these functions clearly belongs to the regularly constituted health authorities and there seems some tendency for the second to pass into their hands in connection with certain diseases. He therefore recommended that the interrelationships between these sanitary and medical functions and the direct economic problem of sickness insurance should be studied by a special standing committee of the Association.

Sir Arthur Newsholme, the other principal speaker at the opening meeting of the convention, also discussed the question of sickness insurance and expressed the view that the insurance problem should be treated as a separate one, but that anything which tended to separate the first two functions of the prevention and treatment of disease was unfortunate from the standpoint of both.¹

The second general session of the Association was devoted to influenza. Dr. A. W. Freeman, of Ohio, discussed administrative measures of dealing with this disease, pointing out that we still lack the theoretical knowledge on which to base a real campaign of prevention, and emphasizing the importance of adequate provision for medical and nursing care. Dr. W. H. Peters, of Cincinnati,

1. The address by Sir Arthur Newsholme is published in this issue of MODERN MEDICINE, page 655.

and Dr. D. B. Armstrong, of the Framingham Health Demonstration, discussed the after effects of influenza; and the latter presented valuable comparative figures showing a definite though not alarming increase in heart and respiratory affections.

The third general session was devoted to the coordination and expansion of Federal health activities. Dr. W. S. Rankin, of North Carolina, delivered a notable address on this subject and urged the appointment of a committee to study the question and to ask for the appointment of a Congressional Committee on the subject along the general lines of the France bill.² Dr. B. S. Warren, of the United States Public Health Service, Dr. W. S. Small, of the Bureau of Education, and Dr. Anna Rudd, of the Children's Bureau, spoke from their different and somewhat divergent viewpoints in regard to the problem of coordination, and Dr. F. R. Green, of Chicago, strongly supported Doctor Rankin's plea for a careful diagnosis of the whole situation before the attempt to secure final action. Dr. L. L. Lumsden, of the United States Public Health Service, urged a nation-wide campaign for the saving of 250,000 lives within the coming year.

The last of the general sessions of the conference was devoted to malaria, and the program was one of the best ever presented before the Association. Prof. C. C. Bass, of Tulane, discussed cinchonization as a factor in malaria control, pointed out the frequency of relapses due to incomplete treatment, and estimated that if physicians treated the malaria cases that came to them effectively, over a period of eight weeks, a 90 per cent reduction would be accomplished in ten years, while the popularization of a standardized home treatment would accomplish a similar result in three years. Mr. J. A. Le Prince, of the Public Health Service, spoke on drainage as an anti-malarial measure, and Capt. D. L. Van Dine on the mosquito work of the United States Bureau of Entomology, while Dr. R. H. Carter, of the Public Health Service, gave an admirable resumé of costs and results of malaria control by drainage and cinchonization in various typical districts of the south.

The Public Health Administration section, under the chairmanship of Mr. C. H. Wells, of Wilmington, Del., held six full and valuable sessions. Among the contributions of greatest general importance may be mentioned a symposium of the privy as a public health problem in which Dr. L. L. Lumsden, Dr. J. A. Ferrell, Dr. E. C. Levy, Dr. C. W. Stiles, and others participated; papers

on venereal disease control by Dr. W. F. Snow and Dr. C. C. Pierce; addresses by Dr. M. P. Ravenel on preventive medicine in the war and by Col. F. R. Keefer on army rejections for physical disability; and papers on the control of hookworm disease, leprosy, tuberculosis, and degenerative diseases. Dr. W. H. Kellogg, of Sacramento, Cal., described a most interesting and somewhat disquieting outbreak of pneumonic plague on the Pacific coast, in which thirteen cases and twelve deaths resulted from a primary bubonic case in a hunter of ground squirrels. It may be noted in passing that a death from typical bubonic plague occurred in New Orleans while the convention was in session and that the Association went on record in favor of a Federal appropriation of a million dollars, to be expended by the United States Public Health Service in the eradication of plague among the ground squirrels of the Pacific coast. The keenest interest was naturally manifested in discussion of methods for securing adequate appropriations for public health work. Dr. E. C. Meyer, of the International Health Board, and Dr. Haven Emerson, of New York, emphasized the need of complete systems of health department accounting and budget making on a functional basis, and Dr. C. J. Hastings, of Toronto, gave a characteristic touch of his whole-hearted fighting optimism to the discussion.

The laboratory section, Dr. R. B. Fitz-Randolph, of Trenton, N. J., chairman, held four sessions, the feature of which was, as usual, the presentation of a comprehensive series of committee reports on standard methods for the examination of water, sewage, milk, air, and shell fish, and for the preparation of various biologic products. An important step was taken by the organization of a standing committee to deal with the reports of all the special committees on standard methods and formulate an official procedure for dealing with them. Numerous technical papers were presented, on water analysis, diagnostic tests, and the preparation of biologic products. Dr. A. B. Wadsworth, of Albany, N. Y., and his associates made an important contribution to the classification of the meningococci and a report by Dr. W. H. Park, of New York, emphasized the failure to demonstrate any primary relation of the Pfeiffer bacillus to epidemic influenza.

The Sociological Section held three notable meetings under the chairmanship of Dr. L. I. Harris, of New York. The first was devoted to the relation of living conditions to health and included a presentation by Mr. Royal Meeker of the valuable family budget statistics of the United States Bureau of Labor Statistics and a discussion of the sanitarian's definition of a living wage

² Such a committee was formally authorized by the Association in a later vote.

by Dr. D. B. Armstrong of Framingham, Mass. The second session dealt with the influence of industrial conditions and relations upon health, and the third with community medicine. Dr. E. C. Meyer, of the International Health Board, spoke on the relation between community medicine and public health; Dr. F. E. Froneczak, of Buffalo, N. Y., on health centers; and Dr. Haven Emerson, of New York, on an evaluation of the Cincinnati Social Unit Experiment.

Section of Industrial Hygiene

The section on Industrial Hygiene was under the chairmanship of Dr. J. W. Schereschewsky, of the United States Public Health Service. The notable feature of these sessions, aside from a discussion of industrial fatigue by Prof. F. S. Lee, of New York City, was the emphasis laid by many speakers on the value of industrial clinics and the contribution made to the practical technic of the conduct of such clinics. Dr. J. S. Billings presented a valuable record card and system for classifying impairments and defects, used by the eastern group of Bell Telephone companies, and Mr. A. D. Reiley emphasized the value of group insurance as a factor in industrial hygiene. Papers were presented on health hazards in the dye industry by Dr. A. K. Smith, of Wilmington, Del.; on health hazards of non-poisonous dusts, by Dr. E. R. Hayhurst, of Columbus, O.; and on the control of the dust hazard in sand blasting by Prof. C.-E. A. Winslow, of Yale University.

The Sanitary Engineering Section, Mr. E. A. Fisher, of Rochester, N. Y., chairman, held three meetings devoted chiefly to reports of committees on sanitary control of waterways, on sewerage and sewage disposal, on sewage works operation, on water supply, on water works operation, on refuse collection and disposal, and on milk pasteurization. This section, like the Laboratory Section, does its work very largely through such a committee system and the annual summaries of current progress which are presented are of great interest and value. Special mention should be made of an able presentation by Messrs. Morris Knowles and M. R. Scharff, of Pittsburgh, of the place of the non-medical man as a health officer.

The section of Vital Statistics with Dr. W. H. Guilfoy, of New York City, as chairman, held four well attended meetings. The papers dealt largely with details of statistical practice,—with morbidity records, accuracy of causes of death, birth registration, industrial mortality statistics, and the handling of non-resident deaths. The last meeting, a joint session with the Public Health Administration Section, was devoted to influenza. Special studies of army statistics and of statistics

of the epidemic in New York and in Connecticut were presented at this meeting, with the results of the Metropolitan Life Insurance Company experience, by Dr. L. K. Frankel and Dr. L. I. Dublin, and a study of variations in incidence and mortality at different periods of the epidemic, by Dr. Edgar Sydenstricker of the United States Public Health Service. The outstanding contribution was an illuminating report by Dr. W. H. Frost on the results of the intensive surveys conducted by the United States Public Health Service in eleven different communities throughout the country, a report which constitutes an invaluable addition to our knowledge of the epidemiology of this obscure and terrible disease.

Food and Drug Section

The Food and Drug Section held four meetings with Mr. H. C. Lythgoe, of Boston, as chairman. Among the problems discussed were the handling of drug addicts, by Dr. E. S. Bishop and Dr. C. E. Terry, of New York, the organization of commercial laboratories for the control of food products, the conduct and supervision of cold storage and dehydration of foods, meat inspection, and the construction and operation of slaughter houses. Prof. M. J. Rosenau, of Harvard, presented a committee report on the relation of food to disease, and Prof. H. C. Sherman, of Columbia University, a report on nutritional problems. Doctor Rosenau's discussion indicated clearly the small part played by foods in general in the causation of disease, and Professor Sherman emphasized the importance of a greatly increased use of milk in the diet, particularly as a preventive of pellagra in the south. Dr. E. R. Kelley, of Massachusetts, strengthened the case for milk by pointing out the small part played by well supervised milk supplies in the production of communicable disease, and Dr. F. O. Tonney, of Chicago, described the excellent organization for the control of milk pasteurization which has been developed in that city.

In addition to the formal meetings of the Association and its sections, special programs were presented on Personal Hygiene, President Dimwiddie, of Tulane University, chairman; and on Child Hygiene, Dr. Julius Levy, of Newark, chairman. The former dealt with such topics as fatigue, mouth hygiene, orthopedics, mental hygiene, and the personal hygiene of problems peculiar to women; while the latter held one session on school hygiene and one on state programs for child hygiene. Groups of persons interested in both these meetings petitioned for the creation of formal sections of the American Public Health Association devoted to the respective fields of

personal hygiene and child hygiene. An excellent exhibit added to the interest of the New Orleans meeting, the most notable features being exhibits dealing with venereal disease, contributed by the United States Public Health Serv-

ice and the American Social Hygiene Association; and a comprehensive exhibit illustrating the equipment and organization of health centers as contemplated by the plans of the American Red Cross.

FULFILLING THE PART OF PHYSICAL EDUCATION IN RECONSTRUCTION

BY THE HON. JOSEPHUS DANIELS, SECRETARY OF THE NAVY, WASHINGTON, D. C.

IF WE count by heroic experiences, the passing of old issues, and the vision of new duties, it has been a hundred years since the Great War began. We will never go back to the world as we knew it in 1914, and the men who seek in this new day to revive old slogans and call into life ancient shibboleths have no place of leadership in this new and better day that is born out of travail and sacrifice and valour. Such men might as well be interred in the catacombs of Salt River so far as their influence upon the thought and action of the era of new progress just ahead of us is concerned.

The issues that call for settlement, aside from the greater ones composed in the Paris Conference,—and that conference will give permanent peace by providing an international tribunal for passing upon international differences and an international police to enforce its decrees,—will make here in America a practical, working democracy that will be safe for the world. Labor must receive a large share of what its brain and muscle provide; we must have a merchant marine that will carry much of the commerce of the world; and our readjustment must be attended with vigilance lest the burdens of the war shall be transferred to the consuming many. But there is a problem more fundamental than any of these, which concerns every individual and the Nation as a whole. The conservation of manpower is perhaps the biggest of all the questions before us today.

The fundamental strength of a nation in peace or in war lies in the vigor and endurance

PREPARE THE NATION FOR ENDURING EFFICIENCY!

Under the duress of war and under the influence of impending calamity we in America recognized with shame our neglect of youth and made plans that this neglect should cease. We promised ourselves that in the future we would conserve our human resources.

Now that the war is over we are told that England will not forget; and we are told that France will not forget. Will it be said that America forgot? That she had use for her young men only for the purpose of war?

This must not be true! We cannot forget!

of its people. We have always known this to be true, but the terrible demands that have been made upon the man-power and woman-power of the world during the last four years have impressed that fact upon us with a grim and cruel fearfulness that we cannot and should not soon forget. We have long known that a large proportion of our people reach maturity limited in usefulness and limited in opportunity because of their indifferent, unwise, or injurious preparation, or lack of preparation, for the demands and exigencies of citizenship. We have long been aware of stunted growth, poor development, bodily defects, physical weakness, physical incompetency, and physical ignorance in our citizenship. Our commanding officers in the Navy and the Army have long held that the greatest service which our communities, our schools, and our colleges can furnish as a preparation for a rapid and effective military training will come when our communities, our schools, and our colleges furnish the government with vigorous, healthy, physically educated young men. But when we threw a great army of our young men into the military scrap-heap at the time of draft examinations, because of physical defects and physical deficiencies, we realized with an intense national apprehension that the long standing disregard of our citizens in their growing periods was a national neglect that might easily lead to national disaster.

No Longer Indifferent

It was only a few months ago that the Allies

The only equipment necessary for the contest illustrated in the photograph above is two six-pound medicine balls. The most poverty stricken rural school can well afford them, and the children should have them.

were counting their youth with feverish anxiety. The fate of our institutions and our ideals was said to depend upon the nation that could furnish the last man. England took stock of her human resources and made plans that her "wasted years" of indifference to the physical education of her children should never be repeated. France has faced her problem with the same determination. In America, seven of our states in two years passed laws requiring more or less active physical education in their schools. Under the duress of fear and under the influence of impending calamity we recognized with shame our neglect of youth, and made plans that this neglect should cease. We promised ourselves that in the future we would conserve our human resources.

Now that the war is over we are told that England will not forget; and we are told that France will not forget. Will it be said that America forgot? That she had use for her young men only for the purposes of war?

This must not be true! We cannot forget!

Because of the extravagant, immediate, and compelling demands of war, we face today the equally im-

Wholesome play forms a part of the daily routine in the schools of New York City.

Exercises of this nature build health, initiative, and character.

portant but less acute and less dramatic demands of peace, realizing more vividly than might otherwise have been possible that the

greatest and most fundamentally important problem of reconstruction before us is the conservation of our human resources. And the world has learned that this conservation may be best achieved through universal physical education, whereby every girl and every boy may be prepared for vigorous, enduring, efficient adult life for peace or for war.

Who Is to Lead the Way?

It cannot be said that we have forgotten,—at least not yet. For there are many agencies in America now working for better care of our youth. In a single week five national organizations unanimously adopted resolutions and appointed committees that are concerned with the establishment of a broad, thorough, universal, physical education through childhood and youth, including informational hygiene, regular and thorough health examinations and advice, and constructive health habits and health training through physical training, play, games, and athletics. A National Committee on Physical Education has been formed with representatives from fifty national organiza-

In America, seven of our states have passed laws requiring more or less active physical education of this sort in their schools. These are Baltimore school children.

tions concerned with various phases of child welfare. And, finally, one of our most powerful associations has established a National Physical Education Service in Washington for the particular purpose of participating in this great campaign.

The Government has authorized and directed the formation of an interdepartmental Board representing the departments of Treasury, War and Navy. This Board is concerned with a very important phase of this problem of conserving the man-power and the woman-power of America. As Chairman of that Board, I know I express the sentiment of my colleagues on the Board, Mr. Glass, Mr. Baker, and the other members, when I state that the success of this interdepartmental Board in its program for the control and eradication of venereal diseases through information hygiene, education, prevention, treatment, and rehabilitation depends upon wide cooperation, and it depends upon the success with which we as a nation construct and operate our readjustment program, and particularly upon the success with which we operate a universal program of informational and applied hygiene along the lines laid out by these national organizations.

Our program of prevention, of cure, and of rehabilitation in venereal diseases cannot achieve an adequate success unless it is associated with a program of instruction that necessarily forms a part of a well ordered, comprehensive program of physical education; no plan for national reconstruction will achieve the full success which the

people of this country should and do demand unless that program includes universal physical education or its equivalent for all the years of childhood and youth. That program must cover informational hygiene, regular, thorough health examinations and advice, and the formation of wise corrective and constructive health habits, emphasizing especially the health, the educational, the growth, and the developmental values of play, games, recreation, athletics, and physical training.

Ohio in Campaign for Health

Practically every county in Ohio is exceeding the minimum of the Hughes Act in establishing the new district health department which begins operation January 1, by providing for workers in addition to the health commissioner, nurse, and clerk required by the law. Several have provided for health commissioners at salaries ranging from \$3,000 to \$4,000 a year, staffs of three or more nurses, and such deputy and sanitary inspectors as may be rendered necessary by local conditions.

Dr. Hugh Cabot Goes to Ann Arbor

Dr. Hugh Cabot of Boston, has been appointed chief surgeon at the University of Michigan, Ann Arbor, and will begin his new duties early next year. Doctor Cabot went to England in 1916 with the Harvard Unit and commanded General Hospital No. 22, British Expeditionary Forces with the rank of lieutenant colonel, and was made Companion of the Order of St. Michael and St. George. He is at present clinical professor of genito-urinary diseases in Harvard University School of Medicine, chief surgeon of the surgical service at Massachusetts General Hospital, and director of clinics of the state board of health.

MEDICINE AND INDUSTRY

Hygiene, Sanitation, Medical and Hospital Service in Relation to Industry

OTTO P. GEIER, M. D., Editor

THE COAL STRIKE AND THE INDUS- TRIAL PHYSICIAN

FOR weeks past the people of the United States have been facing the catastrophe of a coal strike, following the inability of the operators and the miners to find some common meeting ground at their first session in Washington. The intervention of the government with injunction proceedings resulted in a favorable court decision, ordering the miners' officials to cancel the strike order. While the miners were publicly ordered to resume operations with the mines, the men actually did not obey the order, and a serious coal shortage has ensued. Many plants have been forced to close down, while their workers innocently have become the victims of this labor controversy.

The demands of the miners are of vital interest to the public. No serious minded citizen can refrain from giving some attention to the subject. Since these demands are based largely on the plea for better living and working conditions, the medical profession should rightfully be concerned in this controversy.

Much has been said of late as to the value of the physician's possible contribution to the amelioration of the very antagonistic relationship existing between many employers and employees. It cannot be gainsaid that consideration of the health of the worker and his living and working conditions is the most human common meeting ground for these two groups, and that better feeling can be established and enlarged cooperation ingrafted thereon. If these things be true, they should be taken into account in the present coal strike.

The business world generally has failed to appreciate the positive economic value of good health. It may know that disease is a liability, but it does not recognize that health is an asset. Political and social economists have failed equally to recognize the contribution that the socially minded physician might make in the discussion

of labor problems. They do not realize how the physician might at least clarify the atmosphere decidedly about the living and working conditions, which are always forcibly brought out in the appeal to the public in almost all industrial struggles.

If we take the coal strike, for example, we see that the demand for a thirty-hour week and a 60 per cent increased pay is based on the plea for better living and working conditions. The granting of the demands for certain hours and an increased pay would not necessarily assure either better living conditions or working conditions. Yet it is by these factors that the public's sympathies are enlisted. Better living conditions are chiefly made up of good housing, good sanitation, sewerage, good water, pure food and milk supplies. Add to this education and proper recreation, and there will be included a series of things that the community is responsible for, and which must be provided as forming the only sound basis for safe citizenship. If the coal company owns the town, the public should force it to provide these minimum conditions, and the public should be willing to be taxed sufficiently in its coal bills to secure these facilities to the miners and their families.

Likewise the minimum requirements or good working conditions,—safety, lighting, air conditions, the comforts and conveniences of the men while at work,—are also matters that should be regulated by the state. Both these social requirements are without consideration of the wage. They are fundamental and are measurable by the properly trained physician and hygienist.

If the public required duplicate standards of living and working conditions such as have been referred to, the sympathetic side of the particular controversy would then be removed from the discussion and there would be left for adjudication the matter of a proper wage, which many industries are readily solving by adjusting the wage to the ever changing cost of living.

The remaining large question that the govern-

ment must meet, is that of the continuous flow of work to the miner. It is not without reason to say that the government is in position to regulate and equalize the mining of coal and make it less a seasonal occupation.

It would seem that the public has a right to say, after satisfying itself that the living and working conditions are proper, whether the coal miner is or is not a slacker when he asks for a thirty-hour week. All other conditions being equal, the public would probably not single out the coal miner and so extend his leisure hours to a point where his leisure time would become an actual menace, and thus present a new problem for solution.—EDITOR.

AN IMPORTANT GROUP OF ARTICLES

THE editors of MODERN MEDICINE respectfully direct attention to the excellent group of articles presented in the department, "Medicine and Industry," in this issue. There are seven of

these articles. Six are medical papers which were read at the annual conference of the International Association of Industrial Accident Boards and Commissions at Toronto in October; namely, "The Need of Recognition and Better Treatment for Mental and Nervous Injuries," by Dr. Francis D. Donoghue; "The Securing of Proper Medical Service for Injured Persons," by Dr. John W. Trask; "Infections of the Upper Extremities," Dr. P. A. Bendixen; and "Disabilities as Aggravated by Pre-Existing Conditions," by Dr. John W. Mowell; "Better Methods in Medical Service," by Dr. F. H. Thompson; and "How Can Medical Service Be Improved?" by Dr. Morton R. Gibbons. In the January issue there will be printed several other important medical papers which were presented at the Toronto meeting. The editors desire to acknowledge their thanks for the courtesy of the Organization and of Royal Meeker, Commissioner of Labor Statistics, and secretary-treasurer of the Association, for their assistance in securing the manuscripts.

BENZOL POISONING

BY R. P. ALBAUGH, M.D., CLEVELAND, OHIO, FORMERLY DIRECTOR DIVISION OF INDUSTRIAL HYGIENE, OHIO STATE DEPARTMENT OF HEALTH

BENZOL, because of its toxicity, is considered one of the most important industrial poisons. It differs from its homologues in that its poisonous effects occur suddenly, whereas the other hydrocarbons of coal tar produce a gradual narcosis with slow recovery. According to Rambousek, small quantities in the air are poisonous, the limit for animals being 0.015 to 0.016 parts of benzol to one thousand parts of air. Experiments have shown that man, exposed to a mixture of benzol and air, absorbs 80 per cent of the benzol. It is encountered chiefly in the manufacture of the hydrocarbons of the aromatic series, in the technical use of these products, in the removal of grease from materials, in varnish factories and the rubber industry. Benzol is classed with the nerve irritant poisons, and has a general action on the protoplasm of organic cells as well.

Symptoms.—In the mild acute cases there are cerebral disturbances, humming in the ears, giddiness, irritant cough, and sometimes nausea and vomiting. In the more severe cases there are symptoms on the part of the central nervous system, with chilly sensations, tremor of the extremities and, finally, tonic and clonic convulsions. The skin is usually pale and livid and the lips bright red in color. There may be hallucinations, delirium, protracted unconsciousness, followed by death in tonic convulsions. While fatal cases

usually follow this course, death may occur very suddenly, either during exposure or some time following exposure. A case has been reported in which a man was required to enter a still just before the end of his work day and left the plant apparently well, but was found dead a few moments later, several hundred feet from the plant. In chronic poisoning there are severe anemia, hemorrhage beneath the skin and of the mucous membrane, and fatty degeneration of the heart, liver, and kidneys. Clear distinction never has been made between benzol and petroleum benzine poisoning, the symptoms being similar, especially in mild acute and chronic poisoning.

Prevention and Treatment.—Distillation of raw materials requires to be done under effective cooling and in impervious apparatus. Stills, receivers, tanks, etc., should only be entered for the purpose of cleaning or repairing after preliminary thorough removal of all residue of benzol and thorough ventilation. Workers entering such apparatus should be equipped with approved breathing apparatus. Where benzol is handled, every effort should be made toward the confinement or removal of fumes. Because of their susceptibility, females should be excluded from every employment in which benzol is used. The treatment consists of prompt removal of the patient into the fresh air with artificial respiration.

THE RECOGNITION AND BETTER TREATMENT FOR MENTAL AND NERVOUS INJURIES

BY FRANCIS D. DONOGHUE, M.D., MEDICAL ADVISER, MASSACHUSETTS INDUSTRIAL ACCIDENT BOARD, BOSTON.

IT HAS BEEN extremely gratifying to watch the evolution of the idea that *efficient and sufficient* medical treatment is a fundamental of workmen's compensation. I believe that papers before this Association and the spreading of the gospel of light by the members of this Association as they have gone out from these meetings, especially the work of our Secretary - Treasurer, Dr. Royal Meeker, have been determining factors in gradually carrying the truth home.

Last year I called to your attention the disabilities of the hand and the need for specialization in the treatment of this class of injuries if the disability period was to be minimized and the future efficiency of the injured workman maintained. This year I will take it for granted that we all agree that continuous adequate medical treatment is a necessity, and not a luxury, and whether or not the obligation is carried in the law under which a board operates, insurance companies have recognized the necessity of providing care irrespective and independent of their legal obligation if they are to continue to be successful in the compensation field.

A Profitable Comparison

The new law of Nova Scotia, which our good friend Armstrong prognosticated at the Madison meeting, shows how far it is possible to go in the administration of a state fund and, while the terms of Section 1 and Section 3 in regard to medical aid, quoted below, may seem to us drastic, it will be interesting and instructive to compare this direct control with the more lax, indirect or absent control of treatment which obtains under other commissions.

Sec. 1. "Every workman entitled to compensation under this Part, or who would have been so entitled had he been disabled for seven days, shall be entitled dur-

THE USE OF PERSONALITY STUDIES IN COMPENSATION

The volitional index of a patient determines the degree of coöperation that may be counted upon in bringing him back to efficiency. Psychic fear, with or without physical injury, may induce a set of inhibitions most baffling to control.

With the possibility of compensation, there is added the question of motives which further confuses the issues.

The care of such cases constitutes one of the most difficult problems of accident boards, and their classification demands the most impartial consideration of the scientific mind.

ing the period of thirty days from the date of the disability to such medical and surgical aid and hospital and skilled nursing services as may be necessary as a result of the injury."

Sec. 3. "Such medical aid shall be furnished or arranged for by the Board or as it may direct or approve, and shall at all times be subject to the supervision and control of the Board, and shall be paid for by the Board out of the Accident Fund or as herein otherwise provided, and such amount as the Board may consider necessary shall be included in the assessment levied upon the employers."

While the disabilities of the hand and the upper extremity are extremely costly in every sense of the word, there is a group of cases perhaps not so expensive from a monetary standpoint but more trying to handle, and for which less facilities exist than for the greater group of cases, surgical and medical, with which we have most to deal.

Why Medical Advisers Are Needed

No group of cases indicates the value of a medical adviser to a board any better than the group of cases that I am about to discuss.

No man can possibly be an expert in all the lines of medical activity which have contact points with the administration of the workmen's compensation law and, to my mind, the best administration will be obtained that utilizes for the purposes of administration the best that the medical community affords.

I have been aided in the preparation of this paper and in my work as medical adviser by having as advisers and impartial physicians, Dr. William J. Daly, of the neurological department of the Boston City Hospital; Dr. H. B. Eaton, of the neurological department of the Massachusetts General Hospital; Dr. Edward B. Lane, superintendent of the Adams Nervine Asylum; and Dr. Elmer E. Southard, director of the psychopathic department of the Boston State Hospital. I wish to acknowledge publicly my obligation to these gentlemen.

In the beginning of the workmen's compensation law abroad and in the early papers about workmen's compensation in this country, attention was frequently called to the dangers of vale-tudinarianism, not in the sense that the word is ordinarily used as applying to a person in infirm health or subject to frequent illnesses, but in the sense of a person who, by prolonged introspection, acquires the habit of ill health or who does not acquire a desire to return to work following injury.

From our experience, I am convinced that when these conditions exist they represent, in great measure, a lack of diagnosis or understanding of some real condition which, if properly diagnosed, might be remedied.

In the early days of the war before the effects of psychic trauma were recognized, I am informed that the French and English were drastic in their treatment of those who showed mental lapses which had not up to that time been properly diagnosed or classified in psychic pathology.

The treatment accorded to those losing the use of their mental stabilizers under stress of warfare is comparable in a measure with the mal-treatment of those who suffer psychic shock with its various manifestations in times of peace, and who come before our various accident boards.

Dr. E. E. Southard, at the meeting of the International Association of Industrial Accident Boards and Commissions in Boston in 1917, pointed out one source of failure in the proper care in this group of cases.

Personality Studies and Research

Doctor Southard stated that "as you are aware, those of us who deal with mental diseases, whether practically or theoretically, as a rule find ourselves brought into medical councils, if at all, at the eleventh hour. The lack of progress in the psychiatric branch of medicine is due not entirely to the complexity of the topic, but largely to actual neglect on the part of those who are concerned administratively, either in medical schools or in medical institutes, with the development of departments and the choice of research lines. Of course, this neglect is in itself partly due to the feeling of the complexity of the topic, a feeling entirely out of proportion to its actual complexity." But if the hands of medical schools and of medical institutes for research are prone to neglect the nervous system and the mind, it is not at all true of such companies of practical men as are found in industrial accident boards and commissions.

Dr. H. M. Adler, of the Psychopathic Hospital, has presented a study on "Unemployment and

Personality" in which paper he calls attention to three main factors, "feeble-mindedness, paranoid conditions, and periodic emotional diseases" for difficulty in industries as related to mental disease and defect. How many industrial accidents are really due to psychopathic conditions it is impossible now to say, but it is clear that one of the major groups in Doctor Adler's analysis, namely, the feeble-minded group of workmen, must be responsible for many accidents, despite the fact that the higher grades of feeble-mindedness are entirely consistent with good routine industrial work for years and even decades.

These are the cases which, when the routine is interrupted by accident, are so different to bring back to working ability.

Doctor Adler has also made another contribution on "The Psychopathic Employee," which carries the idea still further and gives summaries of actual cases upon which the psychopathic hospital conclusions were founded.

I will not quote further from this excellent paper of Doctor Southard's but will refer you to Bulletin No. 248 of the *United States Bureau of Labor Statistics*, for a resumé of the cases which were studied by Doctor Southard for the Industrial Accident Board of Massachusetts.

Certainly it appears that the proportion of these cases is on the increase and this increase brings with it, unless the cases are closely analyzed, a feeling of exasperating helplessness, a feeling at times that a good law is being hampered and being ridden by cases which, superficially considered, appear parasitic.

But that a large portion of these cases are genuine and are closely connected with or modified by some subsequent injury, is undoubtedly true.

The ability to separate the individual who is generally confounded with this class, namely the malingerer, is a task which is difficult for the skilled medical diagnostician, and it should never be forgotten that an apparent malingerer may have the symptoms of a border-line psychotic condition.

What can be done for these cases and what to do with them, merit careful study.

Psychotics a Potential Burden

The community is full of a large number of people who are hanging on by the skin of their mental teeth, who are potentially and oftentimes really cases of *dementia praecox*, but who are able to sustain the ordinary burdens of life up to a certain point of stress and then become the pronounced psychotic.

The difficulty in handling those cases which proceed from a mental basis arises primarily from

lack of proper classification, and this is due to inexact diagnosis. It may seem trivial to say that it is frequently difficult to diagnose a functional nervous condition; call it what you will, but the fact is that the treatment of these nervous conditions which shade off into each other and resemble each other so closely is so radically different that the success of treating the group depends upon the proper treatment of each component part.

As regards the subdivision of the class, a good working classification of these cases, call them what you will, is: (1) hysteria after injury; (2) psychasthenia after injury; (3) depressed states and melancholia after injury; (4) paranoiacs; and (5) querulents.

All cases come into your office as either physically injured or functionally injured, or a combination of the two. The third class is far more frequent than is generally believed to be the case; simply because an injury does not stick out, it does not follow that this is not an entity. There they are separated by you in their diagnosis of physically injured and functionally injured, sent to your impartials and come back. In that stage I maintain that there comes into the case a psychologic or physiologic evaluation.

As the geologists have a scale of hardness, there may be an *c. v. i.* scale, the measured index of the individual's will to work.—*ergo*, volitional index,—numbers from 1 to 10; 10 the downright malingerer, all others being on the basis of hysterias and psychasthenies, lacking ability to get a grip on themselves for purposes of recovery from injury and return to work.

This evaluation made, your course is changed as to whether you have the functionally injured or the organically injured.

The case of the man who is a problem case it is the function of the vocational director to handle. The medical adviser's function is fulfilled when he has made the diagnosis. He has given the medical opinion as to causal connection and the probable disability, and the active function of restoring the man to the equal scale has been done.

On the other side, in the case of the functionally injured, such a case should be examined as to its *c.v.i.*, its emotional stability, its abulia,—Index of will power, facilitated or diminished mode of release,—and then put in its proper therapeutic channel, according to the last stated factors and its medical diagnosis.

What will we do with our hysterics? It depends upon the form of hysteria. When contractures are present, it must be treated as an organic case and contractures must be put up frequently in the opposite surgical sense to the direction in

which the contracture obtains. Etherization and manipulation often will cure. Tremors will require rest. Certain light forms of hysteria are best treated by work. Major hysteria and hysterical insanity must be treated as insanity *per se*.

The treatment of hysteria depends upon exact diagnosis within the term hysteria. One man may say, "Why, yes, hypnosis is a panacea for all hysterical ills." In many instances the properly directed effort of a sympathetic commissioner may act as a hypnotic agent.

Fear the Basis of Psychasthenia

Dr. Edward B. Lane, of the Adams Nervine Asylum, in Jamaica Plain, has served as impartial physician on many of our cases. The institution with which he is connected is devoted to the care of cases of the psychasthenic variety, and it has been a rule to exclude cases where there was litigation. In their experience, they get practically the same symptoms when there has been no litigation or injury but serious mental strain.

Doctor Lane says that, in his opinion, the very first essential to care for these cases is a sympathetic knowledge of the condition and an understanding of the patient. People who have these, it seems to me, are rare. Each individual case must be known and the various treatments adjusted to it, never forgetting that the condition is undoubtedly a mental one, and it is a state of mind to be relieved rather than any definite lesion.

These patients need sympathy without coddling, and it is the delicate adjustment in this respect that is so difficult to apply. Patients vary so much in their wants and needs that I should despair of laying down any routine treatment. Three or four hysterical patients associated in a ward can demoralize a hospital. What one doesn't think of the other can. Isolation is absolutely essential. Restoration of some of these cases is slow. Doctor Lane says that he finds that it often takes a year before there is recovery. Rarely are recoveries instantaneous; while they may be looked for, they are not to be expected. In the traumatic cases we may find strong mental suggestion of permanent injury. This suggestion sometimes becomes thoroughly fixed and there are subconscious reactions, severe localized pains, hyperesthesia, or anesthesia. It is often easy to divert the patient's attention, but if these symptoms go away they are bound to return on successive days. The more recent the hysterical symptoms, the more quickly may they be dissipated.

Doctor Lane further states that the majority of the cases they see at his institution (psychasthenics) are almost wholly results of the emotion of fear.

Young nurses are quite often prone to say the wrong thing, but such conditions are unavoidable and, if the patients have faith in the medical adviser, they will not be disturbed by these incidents.

Solicitous parents and friends are, in his opinion, more harmful than any errors made by outsiders. Home care is very inadvisable. If a patient can be sent to a place that acquires a reputation for cures without too harsh measures, much can be done. Of course, incidentally in the case of the psychasthenic the minor complaints must be attended to. Simple remedies and placebos must be given and all complaints should be carefully investigated. When patients are satisfied the investigations are careful, they are often willing to accept the judgment of the doctor. If the doctor assumes that there is nothing the matter, the patient knows he has not investigated and will never be satisfied with his findings.

I have not attempted to give a full course in the treatment of this group of cases. There are many books on the occupational and industrial therapy of this important group of cases for those who are interested.

No Specific Treatment Possible

My sole desire at this time is to emphasize the need of calling to the assistance of the boards, men competent to diagnose and advise treatment in this group of cases, and through them to encourage the further standardization of this group of cases. The present method of handling them by exerting constant pressure from the insurance physician, insurance adjuster, or compensation commissioner, is not always a success.

Non-acceptable work forced upon a man or forced at a man tends to develop in him the reaction against work. Forcing a high class man to sweep a floor, may not be treatment; it may be the opposite.

The difficulty of the administration of workmen's compensation by lay boards in this group of cases comes down to the unsurmountable fact that there is no specific treatment for hysteria.

When a case comes to the office, it is not a case coming to the front office looking for information; it is a human being, coming more for relief than for monetary compensation.

NEW YORK'S LOSS IN POPULATION

Owing to the influenza epidemic and the marked decline in the birth rate, the state of New York in the last eighteen months has sustained a loss of approximately 90,000 in population, according to a statement issued recently by Dr. Hermann M. Biggs, state commissioner of health. The decline in the birth rate is due partly to the war, he says and partly to the influenza epidemic. The

birth rates for July and August were 18.7 and 18.8 respectively, the lowest since reliable data have been obtainable.

MEDICAL SERVICE UNDER COMPENSATION LAWS

Certain inadequacies of medical service under the Workmen's Compensation Laws are pointed out in several important papers on general topics read before the Sixth Annual Meeting of the International Association of Industrial Accident Boards and Commissions at Toronto in September. Royal Meeker, in "Minimum Requirements of Compensation Legislation," deplores the ambiguous characterization of certain industries as "hazardous." A disabling accident is a disabling accident wherever it may occur, and Mr. Meeker considers it feasible to provide uniform medical, surgical, and hospital treatment, and money compensation on a uniform scale, taking into account the economic effects of the injury. "Medical service," he says, "must be considered inadequate until provision is made for at least 50 per cent of the cost of industrial accidents to not less than one-half of our working population."

Defects are pointed out in the waiting period for compensation and in the false idea of economy in the time and money limitations of medical service. When left to the courts administration is always cumbersome and unsatisfactory. He emphasizes the real need of full compilation of statistical information.

John Mitchell, chairman of the New York State Commission, emphasizes the shortsighted policy in limiting the time and money outlay in medical service. He cites a case in which a \$200 operation was effectual in preventing a permanent disability. "Not only cure, but rehabilitation, should be the object sought," says Mr. Mitchell. He considers that the fundamental principles of protection to the workmen entered upon in New York involve the necessity for insurance.

Carl Hookstadt, of the United States Bureau of Labor Statistics, urges the intelligent study of data on the relative merits of different types of compensation and insurance. He considers the lack of proper statistics a lamentable weakness which must be remedied if just awards are to be made. He characterizes the provisions for medical service as shamefully inadequate and thinks effort should be concentrated on reducing the number of permanent disability cases.

Compensation law administration is especially complex as relates to medical service, according to Jeremiah F. Connor, who points out the inadequacy of reports and a defect in that the selection of the physician is left to the insurance company. A typical instance is given where this practice was inimical to the contest of the case. The injured man was seen by thirty-two physicians, not one of whom regarded his relations with the patient as confidential, not one of whom would be "his witness." "A system which permits your physician to 'cure your hurts but kill your ease' ought to be removed," says Mr. Connor.

Under the "Collective Liability System" of Ontario, Samuel Price considers there is no constraint to favor either party. By this system the physician is in effect an officer of the Board and, as such, is under obligation to perform his duty without fear or favor. This system also reduces controversy in choice of physician. Mr. Price considers the choice of the physician as of prime importance, and the ambulance-chasing doctor as hampering to good service as the ambulance-chasing lawyer.

THE SECURING OF PROPER MEDICAL SERVICE FOR INJURED PERSONS

BY JOHN W. TRASK, SURGEON, UNITED STATES PUBLIC HEALTH SERVICE, MEDICAL DIRECTOR, UNITED STATES EMPLOYEES' COMPENSATION COMMISSION*

THE underlying purpose of compensation legislation is to relieve the injured employee of the loss and burden resulting from industrial injuries. The loss in these injuries is essentially one of physical damage. Physical restoration is the one means of actually repairing the damage and restoring the loss. Loss of wages and compensation therefor are in a measure incidental. This is true notwithstanding the fact that legislation began at the other end of the problem, first supplying an amount equivalent to part pay for the employee during the period or a part of the period of disability, ignoring largely the question of physical restoration. The granting, however, of compensation for time lost was essentially an acknowledgment that it was not proper to place the burden of an industrial injury upon the shoulders of the employee. This being accepted, it follows that the employee should be restored in so far as possible to his previous physical condition. Physical restoration is accomplished through medical treatment in its broad sense. To be effective it must be competent and adequate.

Not All Physicians Competent to Handle Serious Injury Cases

Most of the cases coming before the United States Employees' Compensation Commission are surgical in nature. The whole question of adequate medical service, in so far as the experience of the Commission is concerned, depends upon getting the injured employee under the care of a well trained, competent surgeon who possesses if possible a not unpleasant personality.

In years past there have been in existence throughout the country many medical schools with limited facilities, giving very inadequate

The question of satisfactory medical care for injury cases seems to resolve itself into ascertaining who are competent, well trained surgeons, with the necessary temperamental qualifications, and where they are located, and then placing the injury cases under their care. The experience of the United States Employees' Compensation Commission has been that the whole problem depends upon the selection of properly qualified surgeons who will conscientiously do whatever is possible toward the physical restoration of their patient. This secures the maximum benefit to the injured at a minimum of cost to the Government.

training. Large numbers of the graduates of these schools are at present engaged in the practice of medicine. They are frequently competent neither as physicians nor surgeons, as we understand these terms.

It is also true that the physician engaged in ordinary general practice, either in the city or in the small town or country, usually sees comparatively few injury cases. Even though he is a graduate of what is

recognized to be a good medical school and though he have a considerable general practice, he does not usually have the opportunity of becoming proficient in the handling of cases of serious injury. His practice includes mainly patients affected with sickness and disease. His experience in the handling of fractures, and often, too, in the handling of infections of the extremities, is limited. He will probably see or have charge of but a few of these cases in the course of a year, often a very few. It is, therefore, more a matter of justifiable surprise when one finds a physician engaged in general practice who handles these cases efficiently and in such a way as to secure the best results.

The impression prevails somewhat commonly, although perhaps not so commonly as a number of years ago, that if you are sick or injured you will get that magic drug or application which will cure you by going to a person, any person, who practises medicine or is known as a "doctor." This may have been more or less true, or at least have been accompanied with less disastrous results, in localities and under conditions when poultices, harmless lotions, or at most bleeding, were the possible extent of the treatment; under conditions when surgery had not developed to the stage it has at the present time, when the practice of orthopedic surgery was limited and crude compared with what it is to-day, before the discovery of the x-ray and its

*Read at the Sixth Annual Meeting of the International Association of Industrial Accident Boards and Commissions, Toronto, Canada, September 23-26, 1919.

possibilities; and at a time when the highly trained medical man was so rare as to be a factor beyond ordinary consideration.

Sending an injured person to a "doctor" is not necessarily furnishing medical treatment; in fact, it may have the very opposite effect, because, as long as the injured person is under the care of an untrained medical man, the chance of his getting under the care of a well trained physician is diminished.

Right Personality of Prime Importance

But in the proper treatment of beneficiaries of compensation acts more is needed than merely a well trained, experienced surgeon or physician. The medical man must have a proper point of view. He must be conscientious and have a desire to do all that is possible for his patient. He must be temperamentally constituted so that he will be agreeable to the patient, and the patient will have a feeling that he is receiving adequate service. A competent man, if he is not agreeable to the patient, or if he does not give the patient the impression of giving adequate service, will not answer the purpose. However, the sincere, competent surgeon, almost without exception, does impart this impression.

The question of satisfactory medical care for injury cases then would seem to resolve itself into ascertaining who the competent, well trained surgeons, with the necessary temperamental qualifications, are and where located, and of placing the injury cases in so far as possible under their supervision and care.

The matter of hospitals gives little concern, for a good physician will give adequate service anywhere, and a physician unqualified by training or temperament will not give adequate service in the most expensively constructed or lavishly equipped institution. Well equipped hospitals, however, are a distinct advantage and make the work easier.

To secure the best possible results, and when dealing with the injuries of others the best possible results constitute the minimum of responsibility, advantage needs to be taken of the special training of special men; that is, of the so called specialists. Eye injuries, wherever practicable, will be treated by trained ophthalmologists, and no physician or surgeon temperamentally qualified for the care or supervision of compensation cases would think of himself treating an eye injury if a competent ophthalmologist were at hand.

Bone and joint injuries will be cared for only by surgeons with training and experience in such injuries, or they will be under the care of com-

petent and experienced orthopedic surgeons, and in this day x-ray control of such injuries is a necessity. Adequate x-ray control is an economy in bone injuries and in suspected bone injuries. The competent surgeon will insist upon it if available. One will no more be guilty of succumbing to the fallacy that all surgeons are equally competent to do all kinds of surgical work than one will succumb to the more general fallacy that every "doctor" is a competently trained and experienced physician.

The Specialist Called For

How to bring about the desired results of securing the service of competent physicians and surgeons only is by no means a simple matter. The great and abiding faith of the average person in his family physician is not a thing easily set aside. It is one of the chief obstacles in the way of furnishing adequate and efficient treatment in compensation cases. This fidelity of the average individual is natural and the reasons for it are readily understood. A physician is the family physician, usually because in his relation to the patient he has been agreeable. He has endeavored to show a sincerity and interest in his cases. He has realized that his success depended upon his convincing his patients of his sincerity and interest, and of establishing in their minds a degree of confidence. With few exceptions, patients will not submit to treatment by physicians or surgeons who do not treat them in such a manner as to show human interest in the individual as well as professional interest in the case. In so far, therefore, as the furnishing of proper treatment under the provisions of compensation acts is concerned, only those surgeons are generally usable who are temperamentally so constituted that they will show this human interest and impress favorably the beneficiaries.

The training, experience, and competency of the surgeon are qualifications which will be required by the responsible commission because the commission knows their importance and necessity. The human interest and not unagreeable personality are attributes which the injured person will insist upon, and it is perhaps proper that he should. He often does not understand the excellence of the medical treatment furnished. It is the personal relation which impresses him most.

The problem of the United States Employees' Compensation Commission in providing treatment has been somewhat different from the problem offered to the compensation commissions of the states. The beneficiaries of the Federal Commission reside in all of the states. Facilities for treatment, however, are not limited to the states

in which the cases occur. The problem is in large part different from that of the commissions in the states with the more dense populations, where the trained medical men are relatively numerous and more widely distributed, and in which the distances to the medical facilities are not great, as they frequently are in the less populous states. On the other hand, if the beneficiary can be moved there is nothing to prevent him being sent from Texas to Chicago or from Florida to New York for treatment if need be.

The Federal Compensation Act provides for reasonable medical and surgical service to its beneficiaries. As only that medical and surgical service is reasonable which gives promise of being effective in bringing about restoration of the injured, the Commission is under obligation to furnish.

The Federal Act also provides that the medical service shall be furnished for a reasonable time. A reasonable time or period over which treatment shall be extended is necessarily that period during which treatment is needed. Treatment for a lesser time or a greater time would be unreasonable.

Medical Facilities Used

The Federal law further provides that this reasonable medical and hospital service shall be furnished by United States medical officers and hospitals where practicable, but that where it is not practicable to use United States medical officers and hospitals the service shall be furnished by physicians and hospitals designated and paid by the commission. The Commission has, in compliance with the provisions of the law, made use of United States medical officers and hospitals wherever they were in a position to furnish the necessary treatment. It has been able, particularly, to make use of the many hospitals and relief stations of the United States Public Health Service, this service having made its hospitals and dispensaries available to the beneficiaries of the commission wherever their facilities warranted and their use was practicable. The Medical Corps of the Army has maintained dispensaries for the treatment of beneficiaries of the Compensation Act at the arsenals and some of the supply depots of the War Department. The Surgeon General of the Navy has equipped and maintained dispensaries at the Navy Yards.

The employees of the Government, however, are at work in all parts of the country, from the Atlantic to the Pacific, and from the Canadian to the Mexican boundary. In addition to the hundred thousand employees at the seat of Government in the District of Columbia there are the

employees of the various executive departments throughout the country—the Customs Service and mints of the Treasury Department; the Immigration Service of the Department of Labor; the Forest Service, Weather Bureau, Bureau of Animal Industry, and other bureaus under the Agriculture Department; the Reclamation Service, Bureau of Mines, Coast and Geodetic Survey, and other offices of the Interior Department; the Engineer Corps engaged in river and harbor work; the arsenals of the War Department and the Navy Yards of the Navy Department (the arsenals and navy yards being large industrial establishments), and, finally, the many employees of the Post Office Department with its post offices in every city and town and its thousands of rural letter carriers, making in all several hundreds of thousands of Federal employees.

Injury cases invariably require immediate treatment. Many injuries are slight, and sending the injured a distance for medical treatment would not be warranted. Many injuries are too serious to make transportation to a distance advisable. As the number and distribution of United States hospitals and dispensaries are limited, the commission has necessarily had to make extensive use of the provision of the law as regards the designation of physicians.

Surgeons Designated

The policy has been followed of designating, particularly in localities where there are numbers of Government employees and in which there are no United States hospitals or dispensaries, or in which these facilities need to be supplemented, surgeons of ample training and experience, of mature age, and of good reputation locally. The Commission has made about 2,000 designations of this kind. The number will be added to as the commission is able to find men with the necessary professional and temperamental qualifications. In the meantime, in the localities in which there are no United States hospitals and in which designations have not been made, injured employees secure treatment from physicians of their own choice, and the Commission will pay in these cases charges commensurate to the service rendered.

For a time, in many places hospitals were designated and not physicians, in the belief that the hospital would represent a group of medical specialists and that of the cases sent to them those requiring the general surgeon would receive his services; those requiring the ophthalmologist, the dermatologist, or orthopedic surgeon, would receive their respective care, and that the necessary pathologic, bacteriologic and roentgenologic services would be available. The Commission early

found, however, that cases sent to hospitals in this way frequently received scant and inadequate treatment. Often they seemed to be placed under the care of an intern, or at times under the care of a practising physician without particular qualifications. They did not often seem to come under the care of a responsible attending surgeon.

Economy in Skilled Service

The Commission, therefore, discontinued this practice, and is requiring that cases in other than Government hospitals shall be placed under the immediate care of a designated physician, where designations have been made. Anything but the most efficient treatment is a serious drain upon the compensation fund, inasmuch as the Commission has to pay part of their wages to the injured until they are restored and returned to work. The better the medical service, the less the compensation expense; also, the better the medical service, the less the loss to the employee.

The commission started out to furnish only ward service for its cases in hospitals, excepting in those instances in which private rooms were necessary for the proper treatment of the case. It has found, however, considerable difficulty in adhering strictly to this policy, as the wards in many hospitals do not furnish a standard of service to which the commission feels justified in submitting its beneficiaries.

Responsibility of Medical Attendant

As regards the responsibilities of the medical attendant, the commission has explained to its designated surgeons that its chief desire is to secure adequate service for the injured; that where the service of a specialist is indicated such service should be obtained; that in bone or joint injuries or in suspected injuries of this kind; the Commission expects adequate x-ray examination and control; that the service of neurologists, pathologists, or other specialists should be secured when necessary; that the purpose of the commission is to make the most satisfactory restoration of the injured in the quickest possible time.

The plan is working out very satisfactorily. Of course, many injuries occur in out of the way places and under conditions where the employee has to be cared for by any physician who is available, and often the results are not what the Commission would wish. It is difficult, however, to see how this can be prevented.

In conclusion, to repeat, the experience of the Federal Commission has been that the whole question of adequate medical service to its beneficiaries depends upon getting the injured employee under

the care of a well trained, competent surgeon who will conscientiously do whatever is possible in the physical restoration of his patient. This secures the maximum of benefit to the injured at a minimum of cost to the Government.

MUSCULAR TONUS AND FATIGUE

Physiologic studies for the purpose of determining cumulative fatigue are reported in reprint No. 543, *Public Health Reports*, by A. H. Ryan, associate physiologist, United States Public Health Service. The amount of tension required to produce a given amount of extension of a group of muscles under controlled conditions was taken as the index of muscle tonus. A decrease in the tonus was noted in the evening as compared with the morning condition. This was more pronounced when the subject was losing sleep. The morning tonus was lower and the average tonus for the day was less than on days following a good night's sleep.

Evidence was thus obtained of cumulative fatigue effects. Sleep at night or during the day was usually followed by a considerable increase in tonus. Strenuous work of short duration was usually followed by an immediate decrease in tonus. Psychic influences (excitement) seemed occasionally to produce an increase in tonus, although fatigue-producing conditions were recorded in the history. In subjects doing relatively light work and obtaining plenty of sleep the tonus varied during the day, the evening tonus being frequently greater than that observed in the morning.

NEW YORK STATE LIGHTING CODE

In a paper read before the Thirteenth Annual Convention of the Illuminating Engineers Society in Chicago in October, John H. Vogt, chemical engineer, Bureau of Inspection, New York State Industrial Commission, traces the evolution of New York's Lighting Code.

In order to know what intensities of light were being furnished in the numerous factories represented, in halls, stairways, etc., throughout the state, and the opinions of the workers as well as of trained inspectors, a large amount of data was collected and tabulated as the basis for formulating the code.

Rules are laid down for minimum intensities. These are subject to amendment and do not become mandatory until July, 1920.

Section "D" provides for the shading of lamps to prevent unnecessary strain on the eyes of the workers but nothing is referred to in the law relating to glare from bright surfaces. "Glare without question has been responsible for more eye trouble than any other factor caused by artificial lighting."

Section "E," relating to distribution of light, provides for the elimination of shadows and of excessively sharp contrasts.

Emergency lighting is provided for use in sudden failure of lighting system.

Prior to the adoption of this code the factory inspector could go no farther than the use of his own judgment in concluding whether a given area was properly or sufficiently lighted. Under the new code a series of tests can be made by the Division of Industrial Hygiene, of the Bureau of Inspection.

There still remains much work to bring up factory lighting to the code rule standard which should be pushed until this important feature of factory inspection is accomplished.

INFECTIONS OF THE UPPER EXTREMITIES

BY P. A. BENDIXEN, S.B., M.D., F.A.C.S., DAVENPORT, IOWA

IN presenting this subject it is not the intention of the author to burden this paper with statistics, or give any definite set of rules for treatment, but his aim will be to give a general survey as to the causes and treatment, and to appeal to you as physicians, and representatives of the Industrial Accident Boards and Commissions to give more detailed attention to the management of the infected upper extremity.

How many of us ever stop and consider the wonderful mechanism of the human arm, wrist, and hand with its powerful muscles, its slender tendons, the multitude of delicate movements possible, its flexibility, its adaptability, and its acute sensibility? And yet how quickly, how easily, how rapidly is this beautiful piece of human machinery ruined and put out of commission by the carelessness and recklessness of the individual himself, and by the introduction of a few germs into its mechanism.

Take Care of Complicated Mechanism

Realizing as we do the wonderful mechanism involved, it then becomes necessary for all of us to try and preserve this wonderful machine which is so indispensable to all productive labor, to all economic welfare, to all progress in science, and to the enjoyment as well as to the maintenance of life itself. Yet with a full knowledge and appreciation of this wonderful machine we allow it to go to destruction on account of neglect either on the part of the individual himself, his employer, or by an unskilled and untrained surgeon.

Does the infected upper extremity get the pains-taking, intelligent treatment that its economic value demands? I believe that it does not. There is probably no surgical condition that is of more importance, that requires such careful and intelligent treatment as that of infections of the upper extremity. To the workman the complete or incomplete loss of function, or the amputation of an arm, a hand, or a finger, often means the loss of his occupation, a change of occupation, or final pauperism.

An external trauma breaks the continuity of the skin, permitting the entrance of bacteria, and making a fertile media, for the growth of the germ. There is no question but that the

staphylococci and streptococci are the most common infective agents, yet other bacteria may gain entrance, namely, the gas bacillus, the tetanus, the anthrax, etc.

Beside the direct causes of these infections we must consider the outside influences which favor these infections. The individual himself may at first consider his injury trivial and give it no attention at all, or he may apply a contaminated handkerchief, or a chew of tobacco which is thoroughly saturated with infected saliva.

The oils in which he works may be the infecting agents. A number of instances have been recorded in which the oil was highly contaminated by the common practice of the employees spitting in the oils.

The employer may be responsible for these infections, by employing incompetent first aiders or an inexperienced surgeon. An inexperienced industrial surgeon came under the writer's observation during the recent war. A physician who came from a small country town was placed in charge of a civilian hospital which was taking care of about 10,000 to 12,000 men. As the injured men came from the shops, dirty and greasy, he immediately became alarmed and gave the wound and the surrounding areas thorough cleansing with a solution of kerosene and benzin to remove the dirt. What was the results of this practice? A wound which was practically sterile, washed out by free bleeding, was contaminated by the freeing of the infecting agents about the wound which drained directly into it. From this same institution, the percentage of infections was extremely high and in a number of instances amputation of the extremity became necessary.

Hydrogen Peroxid Cause of Infection

I am of the firm belief that the indiscriminate use of hydrogen peroxid, which is so commonly used amongst the laymen, is one of the frequent adjunct causes of infections. Why does hydrogen peroxid do harm? For this reason: When it is introduced into a fresh wound gaseous oxygen is liberated, which in turn forces the bacteria under pressure into the healthy as well as into the traumatized tissues, and thus produces infections which otherwise would not have occurred.

As time will not permit a detailed description of infections of the upper extremity, they are briefly divided into various groups.

*Read before the Sixth Annual Meeting of the International Association of Industrial Accident Boards and Commissions, Toronto, September 23-25, 1919.

1. The infections of the distal phalanges, namely: felon, paronychia, subepithelial abscesses.
2. Collar button abscess, shirt stud abscess, frog felon, or, as the French describe it, *en bouton de chemise*.
3. Carbuncular infections on the hand, wrist, and arm.
4. The grave infections of the hand and arms. (*a*) lymphangitis, which may be either superficial or deep; (*b*) tenosynovitis; (*c*) fascial space infection. The pus in these fascial space infections may be localized in the following five well defined spaces: middle palmar space, thenar space; hypothenar space; dorsal subcutaneous space; and subaponeurotic space.

Case No. 1. Gangrenous condition developing in a neglected wound from a slight puncture with a splinter of wood, and resulting in amputation of the index finger.

5. Infections of the arm may be divided into those involving (*a*) the forearm, (*b*) the upper arm with the epitrochlear and axillary region, and (*c*) subelavicular and shoulder involvement.

All of the types of acute septic infections pro-

duce pain in the affected part, with more or less swelling. The location of the greatest amount of swelling does not indicate the location of the pus; quite to the contrary, for the excessive swelling comes in those areas where there is the largest amount of cellular tissue, i.e., on the dorsum of the hand, while in nine cases out of ten the pus is on the flexor side.

The site of the greatest tenderness is of marked importance in the location of the pus.

In the subcutaneous type, which is the most frequent, the involved area is markedly swollen, red, tender, and fluctuating when pus is present; lymphangitis and neighboring lymphadenitis are frequently present, especially in the streptococci infections and in those in which there is no free drainage.

In tenosynovitis there is severe deep tenderness over the sheath of the tendon involved, and the patient does not move the affected extremity on account of the great amount of pain on the slightest movement of the tendon.

In osteomyelitis and septic arthritis of the joints there is a very hard and large swelling, much greater than in any of the other types of infection. The tenderness and swelling are deep seated; in other words, they do not involve the subcutaneous tissue alone, but extend to the deep structures. When osteomyelitis begins, there is a great deal of pain, which subsides in the course of four to seven days, but the swelling persists and pus continues to drain from the wound. An x-ray picture will show the necrotic bone.

The general systemic symptoms vary considerably, depending largely upon the location and virulence of the bacteria, giving no distinct aid in the diagnosis. Personally I have seen ulnar and radial-bursae involvement with practically no systemic symptoms.

The diagnosis in most of our infective cases can be made, (1) by the localized area of tenderness, (2) by the pain elicited by passive movements of the extremity, (3) on the location of pus by fluctuation, and (4) on the history or presence of a wound, which is probably the initial source of the infection.

Prognosis in Such Infections

The prognosis of these infected cases depends upon many outside conditions, but it is the author's firm belief that 90 per cent of the arms, hands, and fingers could be saved by the exercise of proper care and judgment in the handling and management of these cases.

The statistics in this paper are based on the personal observation of the author during the years 1917 and 1918. During this period 1,696

injuries to the upper extremity were treated, 825 involving the right side, and 871 the left side. Out of this number 232 came to him infected, 138 on the right side, and 94 on the left side. You will note the large percentage of infected cases referred. In the history of every case of infection the individual had either treated himself, or had been treated by an over-anxious or incompetent first aider. The infections that were referred had existed from three days to four weeks.

The average time lost by the employe was 11 $\frac{1}{2}$ days, to say nothing about his pain, suffering, and partial disability.

What did the employment of incompetent medical services and the individual self-neglect mean to the employer in the above statistics? It in-

left. The average time lost was 10 $\frac{1}{4}$ days, or the loss of 41 days in 1,464 cases.

Reports of Typical Cases

To show the results of self-treatment and incompetent medical aid, two well illustrated cases are cited.

Case No. I.—J. B., a locomotive fire builder, came to my service on May 27, 1919, with a severely infected right index finger involving the thenar space of the right hand. The patient claimed that five or six days prior to date of examination he was handling some wood to start a fire and while doing same he accidentally ran a splinter of wood into right index finger, palmar side, distal end. He removed the splinter himself, continued work, and did not report the accident. He claimed that the following day he had pain in his finger and that he had continuous pain for five or six days until it became so severe that he requested medical treatment. The photograph shows the condition of the hand at the time of the first examination.

The patient was sent to the hospital. Free incisions were made, and drainage instituted, but in spite of all radical treatment gangrene developed and it was necessary to remove the index finger six days after he reported for treatment.

There is no question in my mind but that this finger could have been saved had the accident been reported. The patient could have avoided the suffering, and the employer could have had his service.

Case No. II.—H. B., a football player, received a slight bruise to his right forearm, lower third. The arm pained him from the time of the accident and a physician was consulted immediately. On account of improper management by the attending physician at the beginning of the case, the arm gradually became worse until an osteomyelitis of the radial bone developed. His symptoms were not recognized and he was treated for other complications. Free incisions were made, and pus drained. It will be noted from the x-ray plate that the radius is considerably increased from its normal size, still showing some signs of the osteomyelitis with ankylosis of the carpal bones at the wrist; supination and pronation are limited, fingers and hand are stiff. The patient has lost about 75 per cent function of his arm.

There is no question but that the function of this arm could have been saved had proper surgical attention been rendered in the beginning of the case.

Prophylactic Treatment

Great care should be exercised in the first aid treatment. Scrubbing of the wound or surrounding areas should not only be avoided but condemned. The first aid treatment should consist of the application of tincture of iodin in and about the wound. In the presence of a considerable amount of dirt and grease in the wound it may be removed by a sharp curette or by trimming the edges with a scalpel or scissors. In punctured wound, especially those produced by nails, the use of a sharp pointed scissor will prove to be the most satisfactory. A complete débridement operation is done from the top of the wound to the dependent area. All foreign material must be removed.

The foremen in the shops should be instructed to insist that every injured employee, regardless as to how trivial the injury may be, report to the first aid station *at once*.

The employer should call attention of the employee either by posters, literature, lantern slides,

Case No. 2.—Improper management of an insignificant injury to the lower third of the right forearm in this case resulted in an osteomyelitis which left the radial bone greatly thickened, supination and pronation limited, fingers stiff, the function being reduced about 75 per cent.

volved the loss of 2,668 working days, to say nothing of what it meant to the employe financially or to their families.

The number of cases that became infected which were treated within the first twenty-four hours were 4, 3 on the right side, and 1 on the

moving pictures, or lectures to the grave dangers and results following the neglect of minor injuries. Self-treatment should be condemned.

After an infection has once been established the affected extremity should be placed at rest by proper fixation splints as it is a well recognized fact that the lymphatic streams are aided materially in their return flow by muscular action. In severe cases rest in bed should be insisted upon.

The systemic use of drugs, such as nucleic acid, etc., to increase leukocytosis has never proved to be of great benefit.

Passive hyperemia as suggested by Bier has not produced the desired results claimed for it. Suction cups may be used in cases of localized abscesses which do not drain freely.

Hot moist dressings, such as saturated boric acid solution, potassium permanganate, alcohol, bichlorid, etc., have been very beneficial and are indicated for reasons which will be mentioned later.

Prophylactic incisions and the common habit of pressing and squeezing the wounds should not only be practised to a minimum, but condemned.

Methods of Radical Treatment

The attending surgeon must have a thorough knowledge of the anatomical structures involved, the location of the trouble, and referring to the well applied saying of the late Dr. J. B. Murphy:

"The blade of the knife is not sensed with vision and to thrust a blind knife, blindly into a human extremity is nothing if not criminal, and, therefore, every acute deep seated infection of the extremity should be treated by exploratory dissection under anesthesia and anemia."

There is no question but that the permanent loss of function may be due more to the surgeon's knife than to the infection itself.

The underlying principle is to make an incision at the proper place, large enough to allow proper drainage and the introduction of drains, preferably gutta-percha. A general anesthesia should be given because complete relaxation is required to do skillful work. Complete anemia is obtained by the use of the constrictor. All operative procedures should be carried out carefully, methodically, and along certain lines.

After the drain has been inserted, hot moist dressings are applied. When no drain is inserted and dry dressings applied, the edges of the wound become edematous and exude serum, which coagulates and seals up the opening. Hot moist dressings should be applied as they prevent the coagulum. An important point to which I wish to call your attention is the flow of serum from the wound. Wright maintains that as long as serum

is permitted to exude from an infected wound the condition is favorable. The serum bathes the wound and brings the lymph to the surface. In the more severe cases of infections the Carrel-Dakin, Dichloramine-T, or modifications thereof, may prove to be of great service in clearing up the infection.

In many cases that are referred to the surgeon the destruction has already advanced to a state where it is a question of trying to save as much of the limb as possible provided it can be made useful and functioning. When we meet with destruction of this kind the utmost care should be instituted. All necrotic tissues should be removed and should not be allowed to slough out. Proper massage and passive motion should be given in all cases where they are indicated. In the treatment of reconstructive disabilities, especially when the joints are involved, accurate and suitable records should be made as to the progress of the case. The chart used by the author has been patterned after the free-hand drawing used at the Clinic for Functional Re-education. The charts that are used at the Hart House, Toronto, can also be highly recommended if they are used in conjunction with Prof. E. A. Botts' series of mechanotherapy apparatus. In cases in which there has been a tendon destruction, tendon transplantation may be resorted to. Various operative procedures have been recommended and the method used will depend largely upon the conditions present, and upon the skill and experience of the operator.

General Systemic Treatment

General systematic treatment has its important place. This is mainly by early and thorough evacuation of the bowels, the forcing of large amounts of fluids, particularly water, the avoidance of alcohol, the eating of nourishing foods, and avoidance of any kind of fatigue. The whole point in treating these cases is not to omit any little detail which might help in any small way in these most vitally important cases.

Conclusions

In conclusion the following points are to be emphasized:

- (1) The wonderful mechanism of the human arm and hand and what little consideration and thought is given to it.
- (2) The importance of considering septic hand from an economic point of view from the very start of the infection until the man has resumed work.
- (3) The great importance of immobilization and rest treatment.

(4) A thorough knowledge on the part of the surgeon of the anatomical relationship of the extremity.

(5) The early establishment of passive motion and massage with record showing improvement.

(6) That tendon involvement can usually be

wholly prevented by early and proper treatment.

(7) That early plastic operation and amputation are desirable after all other conservative methods have failed.

(8) Last, but not least, the old slogan, "No matter how slight the accident, report it."

DISABILITIES AS AGGRAVATED BY PREEXISTING CONDITIONS

BY JOHN WILSON MOWELL, M.D., CHAIRMAN OF THE STATE MEDICAL AID BOARD OF THE STATE OF WASHINGTON, OLYMPIA, WASH.*

I AM particularly pleased that Dr. Royal Meeker should have assigned this subject to me for my paper, as it is a subject that early attracted my interest when I was appointed medical adviser to the Washington State Industrial Insurance Commission eight years ago. In the intervening time "disabilities aggravated by previous existing conditions" have been almost daily referred to me for a decision, and I am glad to be now placed in position to give the results of my observation, assembled though it is in the brief space made necessary by the time allotted this paper.

You will understand that I am confining my remarks entirely to the conditions that have passed under my personal observation during these eight years, and if I have made omissions or failed to give emphasis to certain special conditions which may arise in your minds, it is because of this fact. I am not delivering an assembling paper, but am dealing entirely with conditions that I have reviewed, and the conclusions here presented are those of my own deduction as the result of my own experiences as I now recall them.

Occupational Diseases Excluded

In calling attention to some of the conditions in which we find workmen following gainful occupations, which complicate their condition when accidents which bring them under the com-

A HYPOTHESIS FOR ADJUSTMENT OF DISABILITY CLAIMS

How can preexisting conditions be known and understood by both parties concerned—the employer and injured employee—in the adjustment of claims for disability? Before a compensation act can be administered so that it will be just to both and wholly impartial, it will be necessary to have in the office of the insurance commission a record of the physical examination of every workman, and to require that a general examination be made at stated intervals and a record of same filed with the commission. Then it will be possible to separate conditions that existed before the injury from the accident itself.

pensation act are sustained, I will confine myself to the conditions that have arisen, excluding the diseases generally known as occupational diseases, which are many, but are excluded by the Washington Act.

The handicapped workmen are very numerous when you consider them as a class and they come under your observation as medical adviser to an industrial board. This has been forcibly empha-

sized by the war draft and was one of the problems with which the advisory board had to contend.

For convenience we have divided these conditions into three classes: (1) congenital defects; (2) previous injury leaving a handicap; (3) disease or condition existing in the individual prior to accident.

Congenital Defects Affect Rating

Under the heading "congenital defects" are included all forms of defective vision complicated in the workman who receives an injury to the eye. He attributes all of his reduction in vision to the accident. Not having previous record of the individual's eye, it becomes impossible for the examining surgeon to state definitely just how much reduction of vision is the result of his accident and what his standard of vision was previous to the accident. It is often complicated with astigmatism, strabismus, or a congenital or acquired nystagmus that are not easily separable. This leads almost necessarily to a rating for disability as found.

*Read before the Sixth Annual Meeting of the International Association of Industrial Accident Boards and Commissions, Toronto, September 23-26, 1919.

Then we encounter defects in hearing which seem to be clearly of long standing and in all probability not increased by the accident. The workman, however, actually has an injury to the ear and we are confronted with the same condition as in the case of injury to a defective eye.

We also meet with defects in development of the skeleton and resulting deformities. When one of these individuals sustains a fracture or some injury that leaves permanent partial disability as a result it is a great deal more serious than it would be in a perfectly normal individual, and the handicap is greater.

We also have what is known as "drop heart," where the normal "field of response" for the individual is far below the average. So we are apt to meet a condition which they attribute to their accident, when clearly the accident had nothing to do with it.

The Ubiquitous Hernia

The patulous inguinal canal is a serious hazard to a workman, as it is the cause of 99 per cent of the so-called hernias from accident. It is so well known that it needs no discussion here that a true traumatic hernia is practically unknown, but hernias that come as a result of strain, lifting, etc., have been long in their forming, and their actual appearance through the external ring at that particular time called attention to it. You will often get a history of stinging pain in the inguinal region extending back for months or years, but the courts are prone to hold that a hernia that makes its descent while the man is engaged in his usual occupation, associated with some lifting or strain at the time, is accidental. We have had considerable trouble arising from undescended testicles where the individual claimed injury and the latter condition was found.

We also have had some experience with a unilateral kidney, where examination of the individual receiving an injury revealed the fact that he had but one kidney, and that one not normal, damaged from accident presumably, making the case hard to dispose of in an equitable way.

Then we have been confronted with multiple fingers and toes, and the question arises whether the loss of the supernumerary finger or toe is really a handicap and upon what basis it should be adjusted.

This brings us down to the individual who has inherited an unstable nervous system with its many angles and complications. Accident leads to anxiety and apprehensions in the individual, which are not well founded but largely imaginary. If such an individual has an accident, he

becomes a rather troublesome claimant, and to satisfy him is usually out of the question.

Under this heading come all the individuals who have suffered injuries and who have permanent partial disabilities, or are considered as having such under the compensation act, that have left them subnormal and very much in the same position as the congenital defect, with this exception, however, that we are in a better position to separate the former handicap from the present condition, as it is much more apt to be apparent upon examination and there may be a record of previous condition.

Previous Conditions or Disease

First, we have those relating to the eye. We have seen hemeralopia (day blindness), nyctalopia (night blindness), and psychic blindness in individuals claiming these conditions following bodily injury that could have no connection whatever with their condition. They were either congenital or acquired.

We have seen the following conditions in individuals who have claimed that they had some foreign body in the eye, such as cinder, dirt, or even cottonseed oil splashed in the eye: optic atrophy, choroiditis, iridocyclitis, cataract, corneal ulcer, interstitial keratitis, glaucoma, trachoma, panus, ectropion, trichiasis, distichia, chalazion. A great number have claimed accident caused ptosis, associated with paralysis of the facial nerve, that was not brought about by accident but was due to exposure. Then we have the individual who is subject to migraine and who is often honest in his opinion but claims the attacks are much closer together and more severe than they were before the accident.

We have deafness caused from otitis media or chronic pharyngitis, occlusion of eustachium, and otosclerosis, associated with an injury to the head or ear where it is impossible to say what was condition of the individual previous to the accident. A very large percentage of them insist that their present condition is all due to the accident when from a medical point of view it is quite clear that very little, if any, of the condition is the result of the accident. We also have labyrinthine disease, which is very hard to separate from the condition that the man may have following a fracture of the base of the skull. Not having previous examination it becomes necessary to attribute all of his trouble to the accident.

Static Abnormalities

An injury to the spinal column that of itself is of minor importance, because the gross lesions are easy to separate, is often complicated by one

of the following conditions: chronic torticollis, scoliosis, lordosis, kyphosis, atrophic and hypertrophic arthritis, sacro-iliac relaxation, calcification of ligaments, and chronic lumbago. Then in slight injuries to the soft parts we often find them associated with chronic rheumatic bursitis, an injury to the hand or arm associated with a subacromial or subdeltoid bursitis, or the subcutaneous bursa of the acromion or subcoracoid. In injuries in other regions we find the subgluteal bursa involved and often the prepatellar bursa, the workmen claiming an injury when it is not clearly definite that there was one. The bursa over the olecranon is often involved in miners and other workmen, where it is clearly occupational. Quite frequently we find the subcalcaneal bursa involved.

Chronic Joint Conditions

We are often confronted with a chronic dislocation of the shoulder. This comes up as an accident when in reality there was no real accident in connection with it. These joints have been in the "habit" of slipping out for years, and the joint becomes so relaxed that it slips out even in normal movements, and claim for same comes before the commission as an accident.

Minor injuries to the knee from strain or twist are claimed, and we find a fibrosis of joint or a synovitis that is undoubtedly a chronic condition which makes the joint more susceptible to slight injury. It is very common to find osteocartilaginous joint bodies in the knee, elbow, or shoulder—more commonly in the knee—which become aggravated or set up an acute condition that causes the workman to make a claim for compensation. In fibrous osteitis we get a claim as an accident when it begins to give the individual trouble; osteomalacia, which is occasionally the cause of pathological fracture and which is not connected with any accident other than the mere fact that the bone broke. One case occurred with us in the last few months in which the man firing a donkey engine turned around to pick up some wood and sustained a fracture at the middle third of the femur. In such cases normal healing is retarded, as a rule, resulting in considerable deformity.

Foot Troubles a Problem

Pre-existing conditions in feet usually present quite a problem. An individual who has weak arches or flat feet receives an injury which puts him in bed, lowers his vitality, gives him a general muscular weakness; when he recovers sufficiently to be up, he is very apt to begin to complain of pain in his feet and in the calves of his

legs. He attributes this to his injury, and although he had a broken arch prior to his accident, which is often demonstrated by his shoes, he will contend that the condition is much worse and that he did not have the pain before. In fact, his feet may be worse, although they were not injured. We often find that a man who has a weakened transverse arch or a broken transverse arch in connection with a broken metatarsal has a very painful foot and may be more disabling than a weakened longitudinal arch. The man who has hammer toes and who has an injury in the region of his foot usually insists that that condition gave him no trouble until after the accident. The individual having bunions, hallux valgus, hallux dolorosa (painful toe) will often claim total disability from pain.

In slightly injured fingers we often find Dupuytren's contraction, which has almost made the fingers useless. These individuals are apt to think that they should receive full compensation for the fingers. A number of times we have been confronted with progressive muscular atrophy in the hand associated with a minor injury where it was plainly evident that the muscular atrophy was there before the accident and may have been the real cause of the injury being sustained at the time. As time goes on and this becomes worse the individual is sure to claim that the entire condition was the result of that injury.

The epileptic who has sustained an injury and whose epilepsy in the course of two or three years becomes more frequent and decidedly worse comes back, claiming it a result of his accident. Individuals who have been insane often become insane again following accident, and their friends attribute the insanity to the accident. We often find chronic neuritis associated with an accident persisting long after the injury has become well, but claimants are very prone to attribute the neuritis to the injury received. Tumors of the spinal cord have been claimed as result of accident when operation revealed a condition that could not have resulted from accident.

Injuries to the Syphilitic

Prior to the time that I became medical adviser to the Industrial Insurance Commission I was of the opinion that if a man contracted syphilis and had an injury follow at any time subsequent to the contraction of the disease, the mere fact of his being a syphilitic would influence his recovery from injury. From observation under the compensation act I have come to the conclusion that in an injured man who is a syphilitic in the secondary stage, or at any time prior to the ter-

tiary stage, wounds of the soft parts or fractured bones heal as readily as they do in the individual where syphilis is not demonstrated. In the cases that have frank tertiary syphilis it does have a great influence on repair, and in these cases the active treatment of the syphilitic condition does not appear to influence their recovery to any great extent, or at least much less than text-books would imply.

In this we have *tubes dorsalis* with all of its wake, complicated with accident; nerve arthropathies (Charcot's) coming up as a complication where the man was working and had trouble with the knee while at work which was later found to be a Charcot joint. Then we have rheumatism and rheumatoid and atrophic arthritis in the individual who has had some slight accident which laid him up for a time, and his chronic condition is hard to separate from the accident which he received.

Among the large classes of persons who file claims for accidents are those suffering from cardiovascular disease, aneurysm, varicosities, angina, pernicious anemia, diabetes, toxic goiter, nephritis, gall-bladder infections and stones, enteroptosis, intestinal stasis, abdominal adhesions, plenritic adhesions, gastric ulcers, chronic appendicitis, rectal fistula, hemorrhoids, amebic diarrhea, urethral stricture, pyelitis, stone in the kidney, hydronephrosis, hematuria, orchitis, epididymitis, varicose ulcers, perforating ulcers, eczema, ichthyosis, elephantiasis, leprosy, sarcoma, carcinoma, tuberculosis neurasthenia, hysteria, low mentality, and age.

Goiter Aggravated by Accident

Goiter in some of its forms is quite common in the Washington workmen, especially in the mountainous section of the state. Whole families are often afflicted with it. At one time I saw a family of seven, ranging from eight to twenty-two years of age, every one of the children and the mother having enlarged thyroid glands. In one section of the state it is claimed that even pigs suffer from the toxic goiter and die as a result of same.

We see a great many workmen who have some apparent thickening of the thyroid, accompanied by rapid heart action and nervous symptoms with more or less tremor with no exophthalmus. They become excited in talking about their injuries, complain of profuse sweating, fatigue, etc., which with our present knowledge of hyperthyroidism would lead us to a conclusion that these symptoms are due to a toxic thyroid and not attributable to the accident. They, however, contend that, although they had the enlarged thyroid, they

did not have the other symptoms until after the accident, which has often brought the question in my mind whether it is not a fact that in an individual, who has a mild form of iodo-toxinization an injury leaves the system less tolerant to an increased amount of iodothyronin and results in an increase of his symptoms.

This subject at present is under investigation in the state, and we have a few medical men giving their entire attention to this subject.

Difficulties with the Feeble-Minded

Low mentality in the individual workman complicates a claim for compensation much more than at first thought one would suspect. In my experience this type of claimant has about two thoughts that seem to have become entirely fixed in his mind. The first one is that there is a law compensating a workman for injury; second, that he had an accident resulting in injury. Through misconception of the law and lack of confidence in his advisers he thinks the compensation act is a game in which he is a player and it is only a question of win or lose, and he will not listen to the explanation of the application and intent of the law. He is not satisfied with time loss, but insists on being paid some amount because he was accidentally injured, and will not attempt to take up any gainful work because he thinks he knows of some individual who has had a similar accident and received compensation in addition to time loss. Any explanation offered to show the difference between his claim and those to which he may refer he attributes as being used by the commissioner to win in the contest in which he feels he is a contestant.

Such claimants often boldly assert that they are not receiving justice because of the fact that their cases have been poorly presented to the commission. After going away they are very apt to return and ask to have their claims reconsidered. In the meantime they have hatched a new brood of reasons why their claims should be reconsidered, and end by being very much dissatisfied, declaring that there is a good reason for being a Bolshevik.

Age Factor Important

In the aged workman having a moderately serious accident, as a rule, if the injury incapacitates him for a month or two, he comes to the conclusion that he is not able to return to any kind of work. In fact, he is not able to do much work, and was not at the time of injury, but he is certainly not entitled to a pension the rest of his life owing to the fact that he may only have been working a short time in a hazardous occupa-

tion and the injury was not sufficient to incapacitate a workman, eliminating the effect of age.

In the neurasthenic we have an apprehensive type of individual, one who is always magnifying his condition and is very talkative, using a deluge of words in which he complains that there is a misconception of his condition on the part of everyone coming in contact with him; that he is not getting a square deal; and that his accident has entirely destroyed his capacity for work of any kind. So he augments and magnifies his symptoms, always asserting that things are worse than ever. Back of all this he seems to have one single idea, that is, "How much compensation can I possibly get out of this?"

There is also the hysterical person, who always has something which he wishes to conceal or something which he wishes to avoid. So he proceeds to set up a train of symptoms, which, to his mind, will most impress the observer. The hysteriac is an actor, while the neurastheniac is a talker.

In war, both of these individuals would be classed as suffering from "shell shock." It is quite apparent, however, that we do not have to go to war to have the condition that has been designated "shell shock," because war statistics have shown that at least 85 per cent of the individuals who suffered from "shell shock" returned to the front; that the larger per cent of the remainder recovered on the way home after being S. C. D.; and that a very small per centage continued to have trouble until their compensation had been adjusted.

For this class of people a pension is the worst form of settlement. They should be given a lump-sum settlement, so that their pension is not dependent on their condition and they no longer have to make good in order to have it continued. Then they will recover entirely.

Then we have the individual who has just a plain "yellow streak." He is the individual that you can call by most any name and not exaggerate.

Psychic Effect of Expected Compensation

I should also like to call attention to the psychic effect of compensation acts. The very fact that the law compensates for certain conditions brings about a tendency in a great many individuals to lose sight of the real concept of the Compensation Act, and they insist that they be paid a lump sum of money for the accident, no matter whether or not they have any loss of capacity or earning power. While I am a firm believer in accident compensation and believe that all legitimate accidents should be compensated, a great many conditions arising under the compensation act would

be ridiculous if it were not for the pathetic side, because the idea of trying to get the most possible for a trivial injury has a bad influence not only on the individual's nervous system but on his idea of right and wrong. It is a breeder of dishonesty, falsehood, deceit, and a soporific to the conscience.

Universal Examination the Safeguard

However, social insurance legislation can only take into consideration the general welfare of its people at large and can not pretend to safeguard each individual case. Before a compensation act can be administered so that it will be just and absolutely impartial to the employer and workmen it will be necessary to have in the office of the insurance commission a record of the physical examination of every workman, and to require that a general examination be made at stated intervals and a record of same filed with the commission. Then it will be possible to separate the conditions that the individual had before his injury from the results of accident itself.

TAX ON CHILD LABOR

The tax of 10 per cent upon the entire net profits of employers of child labor in the United States became effective April 25. The Revenue Law of 1918 provides for a tax upon net profits to any mine or quarry in which children under sixteen years work, or of any mill, cannery, workshop, factory, or manufacturing shop in which children under fourteen work or children between fourteen and sixteen work more than eight hours a day or more than six days a week, or after seven in the evening or before six in morning.

RAILWAY SURGEONS SELECT LEADERS

The American Association of Railway Surgeons at its sixteenth annual meeting in Chicago, October 12-17, elected the following officers: president, Dr. Robert McConaughy, York, Neb.; vice-presidents, Dr. Isaac F. Harter, Stronghurst, Ill.; Dr. Paul E. Gardner, New Hampton, Ia.; George W. Thompson, Winamac, Ind.; treasurer, Dr. Henry B. Jennings, Council Bluffs, Ia.; secretary-editor, Dr. Louis J. Mitchell, Chicago; the two last named having been reelected. Members of the executive board are: Dr. Samuel C. Plummer, Chicago; and David Y. Roberts, Louisville, Ky.

VENTILATING PLANS EXAMINED

Besides the other work done by the Engineering Division of the Bureau of Inspection of the state of New York, the latter's Division of Industrial Hygiene is now examining and passing upon, in advance of installation, all ventilating systems proposed both in new construction and in existing factory buildings and mercantile establishments. Inspectors have been instructed to notify all owners of such establishments that their plans for ventilation systems must be submitted to and approved by the Industrial Commission before installation. By so doing they avoid any possibility of having their systems condemned later by inspectors of the Commission, which means needless annoyance, delay, and expense.

BETTER METHODS IN MEDICAL SERVICE

BY F. H. THOMPSON, M.D., MEDICAL DIRECTOR, OREGON STATE INDUSTRIAL ACCIDENT COMMISSION, SALEM, ORE.*

A PROBLEM of every industrial board that has a medical first aid provision is the securing of competent and efficient service to injured workmen. This is a paramount issue. The next in importance is the obtaining of such expert service at such cost as is commensurate with the ability and time rendered, and yet hold to the minimum that insures the funds solvency without abnormally high rating of hazardous work.

This problem, sooner or later, must be solved. It predicates a clear and harmonious understanding between the surgical profession and the industrial Board. It likewise necessitates placing in the Board rather broad power,—power to make and enforce certain rules.

Zoning and Standard Fee Bills

It is my belief that the first movement to better service is a standard fee bill for certain zones, the zones to include one or more states. This zoning idea is held because of the wide variation of fees in certain groups of states, with the overlapping of work in adjoining states. The fee scale should be a minimum scale that would be charged a working man in his respective community. Good surgical service can not be had for less, and there is no valid reason why it should be asked for at a less fee than the minimum. But it must be borne in mind by each medical examiner, that where a minimum fee is allowed, close scrutiny of reports is essential to avoid padding of bills by certain unscrupulous members of the profession, that would make the scale in reality far exceed the minimum. To secure a clear and harmonious relationship between the medical profession and the board, this scale should be chosen by representatives from the state medical society and the board.

Reports Essential to Good Service

A complete, original report, with clear follow-up reports, should be required of every surgeon. Too often incomplete reports allow an injured man to suffer a permanent partial disability that could have been avoided if the medical department had had full knowledge of the case earlier, and placed the man in proper and competent hands. This is especially true in rural districts where bone injuries are most frequently improperly cared for. This suggests the necessity of a suffi-

cient number of claim investigators who can render invaluable service by personal work among claimants and physicians, who can often save friction, and, more important, can report in cases of severity that are not in competent hands for the particular type of case in question. In this connection, one of the powers of the Board should be to refuse service from any surgeon who will not cooperate, or who ruthlessly operates.

A very important rule of the Board should be to require that no open bone work, such as grafting, wiring, pegging, etc., be done unless first taken up with and authorized by the Board. This, with the power of the Board to remove injured workmen from the care of one surgeon and place him under the care of another, will surely decrease the number of men that are surgical cripples rather than industrial cripples. Likewise, every eye and ear case should be treated by an eye and ear specialist. Some discretionary power would here have to be exercised by the Board on account of embedded foreign body cases in outlying communities, reasonable cases to go to the specialists.

There is one class of cases that we find are best treated by the orthopedist—namely sacro-iliac strain. These are fairly frequent, slow of recovery unless rightly handled, and too often aggravated by chiropractors, or neglected by the general practitioner. In Oregon even chiropractors are licensed. Since these are accident cases, the Commission should be empowered to recognize only surgeons as competent to treat such cases.

Selection of Specialists

Competent specialists should be carefully selected in the larger communities to whom men may be sent for special examinations; among these should be at least one neurologist. He it is who can best detect a beginning post-syphilitic condition or incipient insanity that is coincident with, but not the result of, an injury by industrial accident.

Medical service would be improved if closer attention were paid to reconstruction work by selected surgeons. While the leading consideration is restoration to earning capacity, rather than the cost in a given case, three or five hundred dollars judiciously devoted to reconstruction may easily save to the Board a life pension, and return the injured workman to a life of usefulness. This type of work should be done as early as possible,

*Read before the Sixth Annual Meeting of the International Association of Industrial Accident Boards and Commissions, Toronto, Ont., September 24, 1919.

and I would suggest that all temporary total disability cases extending over two or three months, unless the severity of the injury would easily account for the same, should be examined and cared for accordingly.

Direct Study Toward Injury Cases

One other thing that seems essential to the betterment of medical service is the occasional meeting of the county and state medical societies and the presentation of papers that deal with the problems arising between the surgeons and the Board, actually illustrating by stereoscope the good and bad results in certain injury types and thus the necessity of certain Board rulings and actions.

The Board should be clear and firm in all of its rulings and there should be a prompt acknowledgment of all questions or communications from the surgeons.

One other suggestion is to require filing early with the Board all x-ray plates, and the prompt reading of same by the medical examiner, in

order that errors in care of the injured may be detected in time to prevent permanent partial disability that could be avoided.

Abolish Hospital Contracts

One elimination is essential. Do away with the hospital contract system that too frequently renders poor services, overcharges the workman, and are not morally right, as every man should have the God-given right to be treated by a surgeon of his own choosing.

To summarize:

- (1) Pay a better fee for skilled service.
- (2) Give the Industrial Board broader power to regulate services, to make certain rules, and to enforce them.
- (3) Promote a clearer understanding between the medical profession and the Industrial Board by industrial programs at medical meetings.
- (4) Encourage reconstruction of injured workmen and, through investigation, etc., place the men in competent hands as early as possible.
- (5) Eliminate the pernicious contract system.

HOW CAN MEDICAL SERVICE BE IMPROVED?

BY MORTON R. GIBBONS, M.D., MEDICAL DIRECTOR INDUSTRIAL ACCIDENT COMMISSION, CALIFORNIA.

IN ACCEPTING the commission to write the following paper the author wishes it understood that he can not speak for all industrial accident boards and their problems. His opportunities for observation in this field have been markedly limited recently by reason of twenty-one months' service in the Medical Corps of the United States Army. The following remarks apply to California and to some other jurisdictions with which he is familiar.

In discussing this subject there will be included in the term "medical service" all that has to do with the physical, mental, and moral well-being of the injured, from the time of injury until he is returned cured to work, or receives a permanent disability rating.

There is no doubt that medical service whose aims include the functions implied in this statement has been defective. The onus is not by any means wholly upon the medical profession, because many influences beyond its control come to bear. The correction, however, lies largely but secondarily with that profession. The primary duty and initiative lies with the industrial accident boards.

In order to discuss the subject with economy of time there will be referred to here, for the sake of argument, some defects in the system as

now conducted. It must be understood that not all jurisdictions experience the same difficulties. Many of the defects here recorded will not apply to the experience of others.

Psychology and Medicine

Right psychology is probably lacking more often than right surgery. Insufficient medical guidance is present more than is poor surgery. However, poor surgery is too common.

Under the caption "psychology and medicine" come the defects due to lack of unity of interests. There is great divergence of interest incident to the injection of the middleman, that is, the insurance carrier, into this scheme. There are too much business and too little sympathy and understanding. An employer may be wholly in sympathy and have a laudable desire to care for the welfare of his injured employee; but the middleman, by methods with which all are familiar, may prevent and block that interest and solicitude, which might be of utmost value. Then there is delay in securing medical service. This often can not be helped, and in not many instances is it harmful except from a psychological viewpoint. It is to be noted that the results in the United States Army, on the field, were obtained in spite of terrible, but unavoidable, delays.

Another point is that the surgeon works for some one other than the injured person; that is, he is paid by another, and this fact tends to create suspicion in the mind of the injured. The suspicion may not be justified, but nevertheless, it is a reality to be coped with.

Frequently the representatives of insurance companies treat the injured as if he were disabled because of spite for the adjuster; every request or statement by the injured is combated. The injured employee is badgered, sometimes insulted; doubt is cast upon his veracity and he is constantly threatened with loss of compensation; his mind is filled with uncertainty at a time when he is particularly susceptible to shock to the nervous system.

Incentive to Get Well

Improper environment is another important factor. Solicitous friends in misdirected kindness give the idea that the injured is terribly hurt. He is made to feel abused and that his injury is worse than it actually is. His lodges serve the same purpose, and the unions likewise. In connection with this last feature,—the lodges and unions,—comes the question of incentive to get well, or the reverse. Sometimes the injured receives benefits which encourage him to invalidism. Red blooded men are not susceptible to influence of this kind, but, unfortunately, we have all types to deal with.

In conjunction with the psychological and surgical features combined, there is also the purely surgical consideration. This includes the lack of expert surgical attention. A degree in medicine and surgery is not sufficient qualification. To some employers and insurance companies the surgeon looks good in proportion to the smallness of the fee which he is willing to accept. On the contrary, no surgeon is too good. Is it not true that permanent disabilities cost far more than the best surgery? An average physician can count upon his fingers the men whom he would trust to operate upon his loved ones.

Poor surgery is not always to be attributed to poor surgeons. A fault of some most skillful surgeons is impatience. The recent Army experience has taught a telling lesson. Patient application of physiotherapy will often effect a practical cure when radical surgery would have destroyed all chances of anything but a makeshift.

For some reason or other, probably lack of information, possibly lack of interest created by lack of adequate compensation, surgeons have failed to follow up their work. The industrial accident surgeons have not been alone in this

matter. Men in private practice have been guilty of very much the same thing; that is, the matter of restoration of function after injury, which is a very important point, indeed, and it has been grossly neglected. The surgeon has contented himself largely with seeing the bones unite, the tissues heal in proper contour. In spite of the lessons of the text-book, to a large extent, he has allowed the function to come of its own accord. He has not followed up his case in that particular, which is just as much a part of his work as the actual setting of an original fracture. Apparently, surgeons of the United States have lagged behind those of older countries in this matter. The last five years, however, have firmly established the system upon a basis which will prevent it ever again being ignored. The object lesson provided by our own Army and Navy should be taken to heart by every surgeon who attempts to do industrial accident surgery, or any other kind of surgery. Surgeons of high attainment and who ought to be thoroughly familiar with this thing, but who have not been in the Army, are still in the dark and somewhat resistant.

Recently a case was presented for a permanent disability rating. The man was an Italian with poor mental equipment. He had received a Colles' fracture in both arms. The rating asked was for 50 per cent disability with reference to both arms, and the request was made by a skillful surgeon who does much industrial accident work. It was discovered that this injured man had received no physiotherapy whatever. His employer was so advised, and he was also advised that no permanent disability rating would be applicable until proper treatment had been exhibited. Two months later the man reappeared with remarkable restoration of function, yet he had developed it himself; he had had no physiotherapy. This simply illustrates the surprising fact that good surgeons fail in other legitimate functions than surgery.

Occupational Therapy Prevents Neurosis

In the matter of fees it is not so much the actual smallness of the fee which the surgeon receives as it is the constant pressure which is brought to bear upon him to keep fees down and to keep expense down, and the fear which he may entertain that his services will not be called for unless he does work economically from the standpoint of first cost. A surgeon can not, from the fees ordinarily offered, spend his time at physiotherapy. He can at best only direct the occupational therapy, the physiotherapy, and re-education. These departments naturally come

under the work of individuals skilled in and specializing in these matters.

Another lack, then, is that whole system of occupational therapy, physiotherapy, and re-education previously alluded to. Industrial injury practice now demands it. A conservative estimate will place the actual financial saving therefrom at from 25 to 50 per cent in the combined cost of medical service and compensation. One reason for this is that there are practically no traumatic neurosis cases when occupational therapy is exhibited. It is further accounted for by the shortening of convalescence and the restoration of function while convalescence is going on. It must be realized that the longer convalescence is delayed and the longer restoration of function is delayed, restoration of function will be less complete.

After this brief reference to the shortcomings of medical service, let us come now to the suggestion for correction. It will have been observed that running through the foregoing there is the charge of lack of understanding; lack of common interest; lack of willingness to assume the injured man's point of view; lack of willingness to incur expense; lack of foresightedness; lack of knowledge of modern methods, in which the employers, the insurance companies, and surgeons unite.

The correction will come through education. It will probably be demonstrated to the employers and insurance companies by the industrial accident boards that to save function, although the cost is greater at the beginning, will be economy in the end. A few weeks ago a case was presented for permanent disability rating. A rather harsh letter was written for the benefit of the insurance company, for the insurance company had exhibited no physiotherapy and no occupational therapy, and it was apparent that there was function present which needed only to be developed. The insurance company wished to know what was desired and what kind of treatment was to be expected. Proper directions were given. A few days ago the insurance adjuster reported 50 per cent improvement in function after two weeks' treatment, and acknowledged his great satisfaction and complete conversion. Such facts as these are rather elementary, but serve to show that the smallest details are to be considered. It is by this method of proselyting, too, that those responsible for the injured workman will be taught the advantages and will not fear the increased initial expense.

The psychological question is also very important and must be considered and met. There must not be antagonism. There must be a feeling of security in the minds of the injured. There

should be some system established to provide for reassuring the injured, as soon as practicable after his injury, regarding what is to become of his case and what he may expect in the matter of treatment, length of compensation, and restoration of function. He must be assured that his family will be taken care of, and that he is expected to comport himself in a certain manner. He must understand early what lines of discipline will be expected of him. The offer of cooperation should be made to him so that he cannot mistake it. All suspicion should be removed from his mind. The education here must extend to his friends, and his associates, and his union. He must not feel that his injury bears upon him as a penalty, but must feel that he is going to get well, that people want him to get well, and that a job awaits him in accordance with his capabilities when he does get well.

We must attribute the remarkable result obtained in the recovery from wounds of the United States Army in large measure to the unusual environment and to the anticipation most of the wounded feel.

The vast majority of wounded soldiers have looked toward discharge from the Army as their goal. There has been a veritable stampede in this respect and, whether right or wrong, the wounded have shared in this and have looked upon the discharge as a prize for the accomplishment of recovery.

The United States Army provides that no soldier injured in line of duty shall be discharged until he has received all of the physical benefits that the Army can give him. The soldiers know this, and, with the burning desire for discharge within them, make every effort to restore function and secure release. Such a condition can not be simulated in the industrial field, but the illustration indicates what psychological value incentive to get well has. The football player injured at the beginning of a season is striving with might and main to get into the game again. He will submit to any kind of painful treatment that promises restoration. There is the psychology again.

Efforts can be made, at any rate, to avoid circumstances surrounding the injured workman which are the reverse of those of the soldier.

Personnel of Medical Service

Next comes the selection of the surgeon, the hospital, and the others who treat the injured workmen under guidance of the surgeon. There have been two wonderful contributions to medical knowledge and efficiency in this country, virtually due to the war. These are the methods of Car-

rell and the use of Dakin's solution in the treatment of infected wounds, which have revolutionized surgery of such conditions. The other is the system of occupational therapy, physiotherapy, and re-education applied to the injured. The United States Army has at this time a tremendous staff of surgeons skilled in this latter work; of physical and occupational aid,—young women mostly who went into the work through enthusiasm who are willing to stay in it and to contribute the same enthusiasm,—and directors of re-education.

In a short time all of this magnificent organization will have been dissolved. The author has come into close contact with a hospital organized for the complete treatment of the wounded, and he has known the personnel. He knows that many of these workers are available for industrial accident service.

For re-educational work, physiotherapy, and occupational therapy there is a required something more than the relation of patient and surgeon, or pupil and teacher. There is injected a certain personal relationship, the manifestation of personal interest and sympathy. As a matter of fact, the entire system requires a great deal of the personal element. Everyone is not mentally equipped, no matter how competent, to carry on this work. From the highest to the lowest, the individual worker should be chosen according to adaptability and known qualifications. An easy way to secure a personnel would be to make a canvass of the surgeons who have returned from Government service and who have had general hospital or base hospital experience, and to enlist the services of certain selected individuals. They would know how to proceed to secure adequate occupational therapists, adequate surgical treatment, and adequate physiotherapy, and re-education. Remember, the Medical Department of the United States Army and Navy had full charge of installing, developing, and applying this system in their services. Since personality, interest, and genius help so much, this can not be machine made thing to be run by rule. A few years ago the writer had opportunity to visit, in England, a large hospital run substantially on the principles involved in occupational and physical therapy. The organization was wonderful, the results phenomenal; but it was a one-man organization. The one-man feature permeated the whole institution. That medical superintendent knew each one of his 250 different patients, the peculiarities of each. There were 250 different problems. Without that man or one with a comparable genius the place and the scheme would have been a failure.

So let the personnel be selected with the utmost

care, for value and not for low surgical cost. It can be done; it will be worth the trouble.

It would be superfluous in this sketch to try to outline a plan which would be a panacea for all ills of the medical service. However, any plan should take into consideration the psychology of the injured workman and free his mind of apprehension. It should provide the proper environment, and it should provide the proper surgical care; it should include the lately well learned lessons of occupational therapy, physiotherapy, and re-education; it should include a certain discipline to which the injured individuals should be subjected in order that they may not avoid the necessary treatment and environment.

ELIMINATION OF OCCUPATIONAL HAZARDS

The correction of defects which will eliminate unnecessary hazards promotes increased production, creates a higher morale, and makes for greater satisfaction among employees, says Dr. Tracy Hamilton Clark, medical director, National Union Assurance Society, in the October issue of *Medical Insurance and Health Conservation*.

According to Doctor Clark, the personnel of the Division of Industrial Hygiene requires the service not only of physicians, hygienists, and sanitarians, but of highly specialized engineers familiar with problems of light, ventilation, temperature, humidity, and all factors affecting the health of industrial workers. He gives a brief summary of the requirements of industries which involve special dangers and states that efficiency plus humanity demands the control of needlessly hazardous conditions.

POISONED AIR OF INDUSTRIAL SECTIONS

Pine trees die in industrial cities, especially where much soft coal is used, and they die because they can't breathe, says the *Medical Council*, November, 1919.

Deciduous trees that shed their leaves or breathing apparatus once a year may live there, for they renew their respiratory systems every spring. Coniferous trees, especially those with needle leaves, are easily choked by the carbon and sulphur products in the air, and they gradually die. Man is just as much biologically unfitted to live in a poisoned atmosphere as is the pine tree; for he is of the perennial type, not the deciduous one, and his respiratory system is very sensitive.

In addition to this, man is peculiarly sensitive to organisms that gain entrance to the respiratory tract; and the chemical irritation caused by the acids generated in the air of industrial sections renders him all the more susceptible. Indeed, with man, nearly all of the respiratory diseases, including catarrh, are more or less infectious; and if there is a great incidence of respiratory disease in an industrial city, with the gradual generation of peculiarly malignant strains of common catarrhal organisms, the persons in the surrounding country are apt to be infected, even if the air at their homes is pure. The great consumption of gasoline in the cities is also greatly adding to air contamination.

The lesson from all of this is obvious and it is becoming increasingly evident that smoke and gases resultant from combustion must be more intelligently handled and a way found to eliminate this menace to public health.

THE NATION'S HEALTH

Public Health and Public Welfare, Administrative Medicine, Organized Health Service

C. E. A. WINSLOW, DR. P. H., *Editor*

PUBLIC HEALTH MEETINGS IN NEW ORLEANS

THE annual meetings of the American Public Health Association offer recurrent reminders of the rapid progress of both theory and practice in the wide field of preventive medicine and health conservation. The meeting held at New Orleans was one of the most notable landmarks along this path. An attendance of more than a thousand persons, an increase of more than 100 per cent in membership and budget, were the outward and visible signs of a growth, even better evidenced by the serious and substantial quality of the proceedings and the united and militant spirit of service which characterized this note-worthy gathering.

The present of the American Public Health Association is the natural outgrowth of a long and honorable past. Reference to the proceedings of the last convention held at New Orleans seventeen years ago shows only seventy-one papers and addresses as against 225 in the present year; but the quality of the contributions was as representative of all that was best in the American public health movement in 1902 as in 1919.

A review of the proceedings of the recent convention, such as is presented elsewhere in this issue of MODERN MEDICINE, produces an almost staggering impression of the complexity and variety of the tasks of the modern health officer. They involve delicate problems of chemistry and bacteriology, complex questions of statistical analysis and interpretation and the application of skilled engineering construction and operation, as well as the more obvious tasks of medical diagnosis and personal hygiene. They correlate with the sociological problems of the minimum wage, with the economic problems of food preservation, food conservation, and food distribution, with the educational problems of the school, and with the political and legal problems of Federal, state, and local government. Above all, they involve the

study of group psychology and the constructive molding of public opinion if practical results are to be attained.

Dr. L. K. Frankel, in his presidential address, called special attention to three national movements which are pregnant with possible influence upon the public health movement of the present day,—the formal entrance of the Red Cross into the field of public health activity, the agitation of the question of compulsory sickness insurance, and the demand for the coordination and expansion of Federal activities along public health lines. Committees, which should be able to exert a far-reaching influence, were recommended to deal with each of these problems, the first to confer with the Red Cross in regard to the essential correlations between its public health nursing and health center campaigns and the work of the legally constituted public health authorities; the second to consider the inter-relationships between the prevention of disease, the medical and nursing care of the sick, and the compensation of wage earners for financial losses due to illness; and the third to urge the appointment of a congressional committee to report on the organization and development of Federal health activities.

The demand for a solution of the last of these problems by the working out of a plan for a more effective Federal public health service, was perhaps the outstanding feature of the convention. Eleven different bureaus at Washington are dealing with public health problems, most of them with skill and discretion, but none of them with funds adequate for the tasks at hand, and in many cases working at cross purposes with resulting confusion and loss of influence. There is no possible chance of securing action at the coming session of Congress but the next six months should be utilized in the preparation by a duly authorized Committee of Congress of a broad and comprehensive plan which shall realize the ideals striven for by the leaders of the public health movement for half a century.

Throughout the meetings of the Association, there was manifest a vigorous and determined resolve to obtain in the Federal, state, and local fields of public health work the organization, personnel, and funds requisite for the prosecution of a modern campaign for the promotion of the Nation's health. Progress in our knowledge of sanitary science and preventive medicine has been made by leaps and bounds, while progress in the application of such knowledge has been lame and

halting. Doctor Lumsden, of the United States Public Health Service, suggested a campaign for the saving of 250,000 lives during the coming year. It is quite certain that such an objective which would save five times our loss from combat in the war is within range of practical achievement. It behooves the health officer to approach the possibilities of his office with a new and wider vision and to deliver his message for the healing of the nations in a voice that must be heard.

A CRITICAL SURVEY OF PUBLIC HEALTH TOPICS

- I. *The Visiting Nurse Should be a Public Health Nurse.*
- II. *How About the Private Duty Nurse?*
- III. *Why is Poor Ventilation Harmful?*
- IV. *The Health Center.*

By JULES SCHEVITZ, GENERAL SECRETARY, OKLAHOMA TUBERCULOSIS ASSOCIATION, OKLAHOMA CITY

I—THE VISITING NURSE SHOULD BE A PUBLIC HEALTH NURSE

A great deal of good is bound to result from the spirited discussion found in recent issues of nursing and public health journals regarding the definitions and true functions of public health and visiting nurses. One is struck with the feeling that, regardless of some of the apparent differences entertained by health workers, nearly all agree that whether she actually is or is not, the visiting nurse should properly be a public health nurse.

Dr. H. W. Hill's assertion in the July issue of *Public Health Nurse* that the visiting nurse is not a public health nurse, and Miss Brainard's refutation in the same issue, have been productive of considerable discussion among health workers. The August and September issues of the above publication contained articles and correspondence from prominent public health nurses as well as other health workers on this subject. Dr. Lee K. Frankel, for example, disagrees with the stand taken by Doctor Hill. "While her (the visiting nurse's) primary purpose in the home, it is true, has been to render relief to the suffering, it is her value as an instructor that has made visiting nursing take such stride as it has during the past ten years."

Miss Katherine Tucker, of the Philadelphia Visiting Nurse Association, states that "the actual bedside care which the visiting nurse does is now admittedly and avowedly about one-third of her duty in any home which she enters. The other two equally, if not more important, sides of the visit-

ing nurse's services are in terms of teaching the family how to keep well, and applying social treatment where needed, in order to remove the environmental causes of illness, thus making it possible for the family not only to get well, but to keep well."

Miss Tucker offers a possible explanation for the cause of these differences in opinion, when she says:

"We are forced to admit that not all visiting nurses do lay sufficient emphasis on the public health side of their function." This latter view is further borne out by a letter from Miss Mary E. Westphal, of the Chicago Visiting Nurses' Association, who writes, "I do feel that there are some nurses doing this work, without qualifications or any preparation for it, who are not doing the work as it should be done." These admissions indicate in a very forceful manner that, while some visiting nurses are not fulfilling the functions of true public health nursing, yet the answer seems to be that all well trained and properly qualified visiting nurses should be public health nurses.

Dr. S. J. Crumbine, State Health Officer of Kansas, in a recent paper¹ speaks of the "evolution of the visiting nurse into the public health nurse." Yet such authorities as Dr. Julius Levy and Dr. Josephine S. Baker take exception to this view. In discussing a paper on public health nursing by Professor Winslow, Doctor Levy² states: "I believe we ought to make a distinction, from the very beginning, between public health nursing work and the district nursing work. To my mind

¹. Am. Jour. Nursing, September, 1919.

². Report on Child Welfare Standards, U. S. Children's Bureau, 1919.

public health work deals with the prevention of disease, and not with its treatment or cure," and further he goes on, "The greatest development of public health nursing work must not be expected to come from the district health nursing." Following Doctor Levy's discussion, Doctor Baker remarked: "I agree perfectly with Doctor Levy that public health nursing is not nursing the sick; public health nursing is nursing the well. It is the prevention of the disease, and not the correction of the disease, or the treatment of disease."

Yet, Professor Winslow, in a subsequent address on "The Rôle of the Public Health Nurse," reprinted in the *New York Health News* for August, 1919, states: "When I speak of the public health nurse, . . . I include every member of the Visiting Nurses' Association, if the Association is properly organized and recognizes its responsibility for health teaching." Later he says, "In this combination that has been worked out in our best Visiting Nurses' Associations of the care of the sick and teaching of the well, we have not only a great contribution to social nursing, but something very suggestive for the future development of social medicine."

II—HOW ABOUT THE PRIVATE DUTY NURSE?

In the trail of the discussion as to whether the visiting nurse is a public health nurse comes another worker, presenting claims that she, too, does public health nursing. Reference is made to the private duty nurse. The discussion is evoked by a paper presented before the meeting of the Northwest Nurses' Association by Dr. S. J. Crumble, of Kansas, in which he states: "Ordinarily the graduate nurse concerns herself only with the patient whom she is hired to serve; her relation to the family is incidental. . . . The public health nurse has an entirely different relation to the family. She comes to serve the family, as well as the sick individual, without the hope of fee or reward."

Under the title, "Unjust Comparisons," the editor of the *American Journal of Nursing* takes vigorous exception to Doctor Crumble's "comparison of the public health nurse with one whom he calls the graduate nurse, evidently the private duty nurse, as we term her." The editorial continues: "Every time we hear or read a comparison of the public health nurse with the private duty nurse, which exalts the one and lowers the other, we feel indignant at the misconception of the latter's scope of work. It would seem as if the people who are thinking and studying along lines of public health, exclusively, had lost their sense of proportion, or were ignorant of nursing history."

Speaking further of the private duty nurse, "her duties are exactly those described by Doctor Crumble as belonging to the public health nurse."

While the private duty nurse cannot legitimately lay claim to the title of public health nurse, it seems only just to admit that the ideal private duty nurse will take every advantage to impart much valuable health information to members of the family, other than the patient she is serving.

III—WHY IS POOR VENTILATION HARMFUL?

A discussion of the fundamental physiologic basis for current views regarding ventilation is presented by Carlos I. Reed,³ of the United States Public Health Service. The views of the early investigators along this line were many and diverse. Most notable among these was the theory, advanced by Brown-Sequard and others, that the harmful effects of poor ventilation depended on the presence of expired substances. The conclusions reached by the New York State Commission on Ventilation in its recent experiments, that neither excessive carbon dioxid nor bad odors in any way caused discomfort or decrease in efficiency, disprove the stand taken by these earlier workers.

Investigators of recent years have proved that conditions of ventilation depend upon control of moisture, temperature, and motion of the surrounding air; and that, when moisture and temperature rise, even moderately, and the air is allowed to remain stagnant, there is a decrease in physiologic efficiency; and that this effect is dependent on the interference with the elimination of heat from the body. If this interference is sufficient, the body temperature may rise.

The rise in body temperature acts in a variety of ways, to the detriment of the body, as shown by disturbances of metabolism, decreased working power, and early onset of fatigue. Neither the diminution of oxygen, the increase of carbon dioxid, nor the generation of odor, are of themselves factors in these effects, with the possible exception that decrease in oxygen may affect the appetite.

On account of the similarity of observed effects of fatigue to those of the now recognized poor conditions of ventilation, it is apparent that there is a close relationship between the two conditions and it may be that the effects are the same, though the mechanism is not clearly outlined.

It is apparent that the processes underlying the action of increased temperature have not yet been sufficiently determined, but it is possible that the

³. Am. Jour. of Public Health, September, 1919.

temperature nerves of the skin, the hydrogen ion concentration, the osmotic properties of the cells, and the electrical reaction of the body tissues may be of importance.

V—THE HEALTH CENTER

"A health center is a place where people may come to learn how to keep well," is the keynote of a paper by Dr. Merrill E. Champion, of the Massachusetts State Department of Health, at the International Child Welfare Conference held last May. While the subject of his address is "Health Centers for Pre-School Children," he dispels the view that these children require individual attention by stating that "we should have health centers which should include all, from the baby to the adult."

The health center is a distinct advancement over the "clinic," in that it signifies more especially the idea of disease prevention and health preservation, rather than medical treatment and disease cure. The efforts of the health centers should be constructive and positive in nature; "the workers should deal in 'do's' rather than in 'don'ts.' The important factors in a successful health center are the enthusiastic public health nurse and physician who can inspire in people the desire to pursue the ideal of health. Doctor Champion believes that the conduct of the health center should be left to the municipality.

In small communities the whole health center will be under one roof. In large places there

should be one main center, preferably in some municipal or county building, with as many branch offices as are necessary to reach all the people conveniently and to give a sense of neighborhood proprietorship. When a community is too small or too poor to maintain a health center, the only course is the combination of two or more similarly situated communities to provide requisite service for all.

"I doubt if it is wise to combine a hospital with a health center," says Doctor Champion. "This same objection would hold good for nose and throat operations. I do not see that they belong in a health center. Eye and dental examinations might be included. Dental treatment would be included at first, at any rate, simply because the people demand it. Such a health center would serve as a great educational center, comparable only to our public schools."

SOUTHERN MEDICAL ASSOCIATION

The Thirteenth Annual Meeting of the Southern Medical Association was held at Asheville, N. C., November 10 to 13, 1919. Special sessions were arranged jointly with the American Child Hygiene Association.

Public Health questions were markedly prominent on the program and a number of public meetings were held on problems of disease control and prevention.

Dr. Franklin H. Martin, Chicago, gave an address on "Medical Organization," and "Medical Organization and Public Health" was the subject of an address by Dr. Alexander Lambert, of New York. The Southern States Association of Railway Surgeons, as an auxiliary, provided a symposium on traumatic surgery.

The accompanying photograph was taken at the annual dinner of the Wisconsin Anti-Tuberculosis Association, held at their own building, the Health Service Building, in Milwaukee, October 31, 1919. About five hundred people attended.

THE LARGER FIELD IN TUBERCULOSIS

BY ALLEN K. KRAUSE, MANAGING EDITOR, AMERICAN REVIEW OF TUBERCULOSIS, BALTIMORE, MD.*

THE title of my address is of your committee's choosing. To do justice to it is really a formidable task. When you ask me to discuss a progressive program, I assume that you expect me to lay down lines of attack against tuberculosis that will work, procedures that will bring results, results that will be reflected in our daily life in such a way that every man and woman will begin to wonder what has happened to their old acquaintance, Consumption. When you ask me to do this, you lay a burden upon me that for centuries has taxed far abler talents than mine: you ask me to lay plans that will reconstruct society; to have our individuals put the living of a hygienic life above the amassing of a competence; our captains of industry everywhere, the health of their communities above the returns from capital; our officials, the abolition of rookeries above the erection of monuments, and the enforcement of laws above the making of them; our schools and colleges, the training of men for service above that for position; our medical schools, the example of Trudeau above that of the day's medical Croesus; our churches, the all round development of their people above marble and cloth and vessels of gold. When community or public health becomes as intimate a part of everyone's thoughts and plans and ambitions as the struggle for a motor-car, or the changes in the value of commodities, or the "front" to be maintained before all, or even the selection of that spot above which a final R. I. P. shall be chiselled bold, then we shall begin to see what can happen to our old friend, Consumption,—and to many another sticker of a crony besides.

A Price for Civilization

Tuberculosis is a price we pay for our civilization. The two are inextricably commingled and are continually being reflected upon each other. But this fact should not in the least condemn our civilization, or even impugn it. Whatever we may

Whatever makes for better conditions as regards tuberculosis infection and disease tends, with a very few exceptions, to reduce the incidence or deleterious effects of all other diseases.

A community of "no-tuberculosis" at once presupposes a community of cleanliness; of temperance and sobriety; of adequate light, space, and air, both within and without its habitations, offices, and factories; of labor enough for all; of economic and industrial over-strain for none; of an intelligent and enlightened medical profession to correct the disabilities of man; of a strong and sympathetic citizenry with an advanced point of view.

think of its present character, whatever its inequalities, we cannot gainsay that it is the best that man has yet evolved. If our criteria be standards like the distribution of comforts, the position of women and the child, the toleration of slavery and of cruelty to the criminal and unfortunate,—and I consider these fair tests,—then we stand on a rung from which we can look down upon every age that has gone before. But while we congratulate ourselves upon our position we must remember that civilization is no more static than is anything else in the world. In constant flux, it is nothing more nor less than the individual writ large; and its lineaments, its mind, its movements, and its ideals are simply Gargantuan projections of the individual's. Where civilization is headed and where it is going, no one can tell. But it is going somewhere; it will never stand still, though a thousand Canutes issue their commands. To every one who thinks, it is continually calling, "What are you going to do about it?" And if a man be of a constructive turn, he should venture a reply.

I cannot be a whit different from any of you in longing for that ideal state of society,—in other words, that state of mind, that point of view,—that will demand and allow for every soul enough light, enough space, labor and toil enough, to keep the human machine trim and fit. But in dreaming of such an ideal I am always struck with the futility of forcing a mechanism upon society to upset it and make it fit an ideal. Among free men it is the people who are the state, and any change of the state ideal must originate and come into being through a change of the popular ideal. There can be no real evolution by revolution: there may be much action and reaction, but never evolution. And it is as true as anything can be that the people, the mass, will

*An address delivered under the title, "Medical and Scientific Premises for a Progressive Program Against Tuberculosis," before the Fifth New England Tuberculosis Conference, Providence, R. I., October 16, 1919.

evolve just as surely as the individual will evolve; and this is certain no matter how repressive may be the Bourbon preservers of the existing order or how explosive its destroyers. Where there is the ballot,—and the ballot is coming all over the world,—there can be no revolution that is based on reason: it can be only passion that resorts to this "corrective" of social evils. If this is not true then man writes himself down as a fool, for he is putting the dynamite under what he himself has helped to erect or maintain.

Put the Health Message Across

I am led to these reflections because the more I look into what we call the tuberculosis situation, the more I am impressed by the fact that it cannot be considered without paying attention to the society in which it now exists. As a consequence the problem immediately presents itself of how to deal with this state of affairs, if we are to make any headway. There seem to be only two alternatives. One, the more spectacular, the more appealing to those who love the limelight or to those whose sympathies now and then play havoc with their intelligence, is to damn the existing state of affairs as all wrong and to come forward with a new broom: to make a clean sweep and then to start this world anew with the few immaculates who have escaped being caught in the refuse. The other alternative is to search through this sorry world of ours in an endeavor to find some solid ground peeping above the maelstrom, to hunt for a foundation and gradually enlarge this until it blocks the current or perhaps fills up the pool, providing the while an ever widening refuge for the poor unfortunates who have been struggling in the waters. I am still old fashioned enough to believe that if the appeal to reason will not be listened to, then the cry to passion would better not be uttered. I believe that every progressive movement must be based on information presented to the intelligence, and that the reconstruction, the evolution, of society can be accomplished in only this way. I believe that the *modus operandi* of any progressive movement against tuberculosis must follow this line. *We must get to the people, to all the individuals who constitute society: in the language of the street we must put what we know about tuberculosis across.* And although I may be here more to tell you what we know about tuberculosis, the matter of "putting this across" shall be my underlying text. Beneath every medical and scientific premise that I may establish is always the more fundamental premise that the man on the street and the dweller in the tenement know what you and I know. This vulgarization of information is ab-

solutely essential to any progressive movement. When a tuberculosis specific or a practicable method of prevention has been invented, there may be a different story to tell. But until this time arrives, there must be perfect cooperation between the organized authorities of the state and the people. With the people indifferent, the state will labor to no effect: with those in official position holding back, the efforts of the individual will avail little. Short of a catastrophe,—and tuberculosis does not work in cataclysmic fashion,—the only conceivable remedy for indifference is information driven home.

But let us get back to our particular topic. I would call that movement progressive which with increasing ratio would result in reducing infection, morbidity, and mortality from tuberculosis. If we reduce infection, we thereby reduce morbidity, and mortality. If by any special means we reduce morbidity, we thereby reduce mortality, though not necessarily infection. If we possess measures that directly reduce mortality, these need have no effect on infection or morbidity. The great desideratum, therefore, is something that will work against infection, though until we have hit upon a perfect anti-infection mechanism we must continue to make every possible direct attack on morbidity and mortality.

Not Contracted by Voluntary Association

Now I consider that we already have in our hands all the necessary medical and scientific information upon which may be based the premises for a progressive program against infection, morbidity, and mortality: and this is my answer to the superficial accusation that we are not getting anywhere with tuberculosis. I hope to prove this, and should be glad to have a similar proposition proved for any other infection that is not contracted by voluntary association.

We may first take up our scientific information. Most of this has to do with infection and morbidity.

For all but a thoroughly negligible proportion of infections, we know to a certainty the original vehicles of infection. These are human sputum and cow's milk. There is not the least doubt concerning the method of infection by cow's milk: it is by ingestion. The method of infection by human sputum may be debatable. The enormously widespread tuberculization of the human being during the first few years of life seems to me to weigh decisively against the opinion that intimate contact with the sick, the "open" consumptive, is the common method. This is a frequent method, undoubtedly: but that most children, or

even a fair proportion of them, are intimately associated with consumptives is simply not in accord with the facts of every day life. If, too, this were the common method of infection we would of necessity find many more tuberculous infants, for whom physical contact with adults is the most intimate. Yet 10 per cent of *infected* babies (under one year) is the high average maximum proportion in statistical studies; and from here the curve of infection rises steadily, keeping pace with all those activities of the child that take it out of the home and interrupt the continued intimacy of familial association. It seems to me that to explain the bulk of early infection we must look somewhere else than in the home. Nor do we have to go far to find all the human sputum,—all the loose bacteria, bacteria of all kinds,—that the most voracious bacteriologist might desire to snare. I don't know when the first anti-spitting law was enacted nor how many are buried in the codices of the land, but this I do know: that in this year of grace our highways are still besmeared with the offal of the throats and lungs of myriads; and I am equally certain that every child, at play in these highways, day in and day out, is putting into its mouth the sputum of others, sputum that can and does contain every variety of pathogenic micro-organism to be found in the sputum of walking men. Why should we be amazed when the students find so many children of healthy parents with tuberculous tonsils and adenoids? Why shocked at all the lumpy and fistulous necks? Why puzzled because we cannot eradicate diphtheria completely? And then we walk through all this sputum and bring it to our homes; and in the handling of our shoes even you and I have ample opportunity of acquiring others' sputum to ourselves. Right here on our highways plain to all, are the very conditions by which one consumptive can in an hour infect scores and hundreds of his fellow men; and seeing and knowing this, we need not search much further for cumbrous mechanisms to explain the rapid and universal tuberculization of the race.

Prevention That Is Practicable

What premises for a progressive program does this information suggest? First, that we must see to it that all milk that enters our households comes in clean. Every man who buys his milk, should buy it free from pathogenic bacteria. To reply that this is not a new weapon of attack is not to the point. What is pertinent is that efforts in this direction have heretofore been either only local, or wasteful, or inadequate, or based on misapprehension of the results to be obtained.

Under present conditions, to meet the situation nothing can be more wasteful, extravagant, and unproductive of real results than the slaughter of infected cattle. We have learned a tremendous lot about tuberculosis since this was the method put forward to prevent bovine infection of man. All know what has been done. Money has been poured out; herds have been depleted; evasion and trickery have been resorted to; animosity and strife have been engendered, and—tuberculous cattle are still as common as can be. This whole episode in the antituberculosis movement should teach a pregnant lesson to those who are so certain that they can eradicate human tuberculosis by the mandatory segregation of the sick. If we cannot wipe out a disease by the wholesale slaughter of dumb, pent cattle, what is there that would lead us to believe that we can get anywhere with the policy for the permanent or periodic captivity of aspiring man? I say "policy" because its actual practice and enforcement are beyond my imagination.

The only effective and economical way to prevent milk-borne infections is through the public control of the distribution of the commodity. From the time that milk enters the corporate limits of a community until it reaches the consumer it should be under the care of the authorities. There is to-day no more reason why a municipality should tolerate the private retail sale of milk than that it should put up with the pump on every corner.

The municipal control of milk should be the business of the Board of Health or a subdepartment under the latter's supervision. All milk that is to be consumed in the municipality should be brought by the producer or the wholesaler to stations that are set aside for its handling. Here trained employees of the milk department should bottle and pasteurize it: and from the several central stations it should be transported under civic control to the consumer, and the cost collected by the city.

Civic Distribution of Milk

Some such method is perfectly feasible. More than this, it would be vastly more economical than are the present methods and would undoubtedly bring down the cost of milk to the consumer.

Central collecting and distributing agencies would of themselves eliminate much waste that present methods entail; the producer or wholesaler would have only one or, at the most, several deliveries to make, and would carry on his books no slow or bad accounts. Distribution would be routed; there would not be, as at present, dozens of companies crossing one another's territory. Above

all, there would be safety for the consumer; and the responsibility for any lapse in the handling of the milk could be immediately fixed and shortcomings remedied. In its board of health every municipality already has in existence the nucleus of the organization that would control the milk supply: the increase in taxation necessary to equip and maintain it would be relatively slight. The argument that the taxpayer should not help to pay for the other man's milk is no more valid than the one that he should not help to pay for the latter's water and the collection of his garbage. Milk in adequate amount for the very poor would be supplied by moneys from public funds, or, as at present, from those of semi-public organizations.

Eventually some such plan is bound to be evolved. Civic control of the distribution of milk with pasteurization by civic authorities must form no small part of any progressive program to combat many infections, particularly tuberculosis; and it is one of our duties to speed the day when it shall arrive. Have the farmer slaughter his *sick* tuberculous cattle by all means: work with him for every possible improvement of his dairy: but make your loudest demands for municipal milk supplies that are regulated basically like city water supplies. Control the sources if you can; but if, as in most places, you cannot, control collection and distribution. Pasteurize the milk as you filter or chlorinate the water.

Opinions That Work

To bring into being a society that will not countenance public spitting must ever be a major premise of any progressive anti-tuberculosis program; yet it is in this very respect that our voices have been weakest and we have fallen down most miserably. The very fact that in his ascent from savagery and barbarism man has assumed some strong opinions,—opinions that work,—about the propriety of public micturition and defecation assures me that he is capable of being educated regarding spitting.

We once made a brave and showy beginning,—if you call this method of approach education. In thousands of places all over the world we passed laws that sounded as if they meant business. Then we buried them deep in big books between other laws and had copies beautifully framed and hung high up in railway coaches and post offices and other such places; and then,—well, you know the rest.

I imagine that it was the dust kicked up by Cornet, and the barrage of vapors turned loose by Flügge and his band that blotted out our path and threw us off our base, and for the last twenty

years or so made us reach for a gas mask whenever we thought of a plague coming. They influenced our sense of proportion mightily and made us just a trifle careless about sputum. It is curious that, if sputum is dissected and further dissected, and worked out into many figures and the figures set down in rows of columns in a book we should turn pale at the terrific possibilities of sputum; while if it is whole and fresh and everywhere next at hand, this should be of relatively trifling importance. All this may be part of the workings of "science," but it has about it none of the savor of common sense, without which all scientific observations must remain as nebulous as if they had never been made. When I prove that I can produce tuberculosis by inoculation, I do not prove thereby that human beings are *commonly* infected by inoculation: I should not even make the suggestion; nor when I find bacilli in dust and cocci in droplets suspended in the air, have I in the least shown the *common* method of any infection of man.

At any rate, human sputum on our streets must go; and it is our bounden duty to work everlasting-^{ly} to that end until this happy day arrives. Picking out one day a year and on that day haling one or a thousand men before a magistrate and fining them a dollar each will not get us anywhere. Our program must be planned with the idea of never a let-up of propaganda. This propaganda should not, in fact, it need not, tell anything but the plain, unadorned truth: but let this truth be told. Don't insult intelligence. Don't make people tremble before mythical and lying cocci and bacilli that swoop relentlessly through the air with claws outstretched, fangs and tusks poised, and beetling wings. Such representations might be justifiable for people who believed in gargoyles and griffins, but they have no place in our time. Besides, a public that finds out that you resort to sensational exaggeration and untruth to strengthen your cause, will put it down as weak; and cannot be blamed for looking askance when you again stray into the narrow path of truth.

Without cessation, yet ever taetfully, we must lay the truth before the people. We must aim to get the sympathy of the officials and of all individuals. As a growing number of the latter take upon themselves advisory, corrective, and police duties, our official and professional labors will be made the easier; but it is we who must organize and direct this movement, with never a qualm of discouragement. The object to be achieved is without a single demerit: no cause can be stronger whether from the point of view of utility, of estheticism, or even of morals. For

these reasons it invites our very best efforts; and when these are applied it will succeed even beyond our utmost expectations.

Pathological and experimental data furnish us information upon which we may base other premises for a progressive program against tuberculosis. It is absolutely certain that only in very rare instances does a tuberculous infection from without proceed uninterruptedly to the development of a condition that we recognize as disease. Between any exogenous infection and the appearance of symptoms there is a longer or shorter period of latency, of quiescence, of maturation, of development,—call it what you will. I am not here to debate what has become almost a doctrine, namely, the development of adult manifestations from childhood infection, or to dispute whether one or many infections is the common lot of man. I state merely what I think has been definitely proved,—that few infections go straight on to manifest disease. In many instances, particularly in children, there may be, however, certain definite disturbances which although surely tuberculous are not generally recognized as such and which, therefore, are overlooked so far as their connection with tuberculosis is concerned. In many children and adults warning signals of a relatively obscure and intangible nature are frequently thrown out long before frank tuberculosis develops, yet this relationship to tuberculosis is only too often unthought of. There arise, therefore, several premises which we might fit into our progressive program. None are concerned with preventing infection, but all would aim at reducing morbidity.

One of these premises would make it incumbent for us to arouse the medical profession to the significance of affections like phlyctenular conjunctivitis. This minor disease is quite prevalent, especially among children; and the weight of the better medical opinion is that it is nearly always a manifestation of tuberculous infection. In very many cases it may be the sole symptom; now and then it precedes the graver evidences by several weeks or months. As matters now stand, its tuberculous background is completely disregarded by the rank and file of physicians. It is treated as a minor and independent ailment of the eyes, whereas it should be treated as tuberculosis. There is no doubt that if its full meaning were appreciated and if a modified tuberculosis regimen were employed in the treatment of phlyctenular conjunctivitis, not a few attacks of undoubted tuberculosis and, consequently, a certain number of deaths would be averted.

We might indulge in the same prediction if practising physicians as a class were alive to

their full obligations when consulted for a variety of obscure constitutional conditions,—unusual nervous irritability, abnormal tendency to fatigue, chronic under-nutrition, obscure though slight anemia, etc. I am not now discussing the early diagnosis of clinical tuberculosis. As often as not, we cannot find enough to dignify the trouble with the term, tuberculosis; and as often as not the distemper is transient and passes over without special measures being directed against it. Yet in only too many of these cases the future explosion proves that tuberculosis has insidiously been getting in its work. Where a positive diagnosis of any disease cannot be made, I believe that these cases call for a modified tuberculosis treatment. The word tuberculosis should never be mentioned to these patients, except by way of warning them of eventualities that may occur: but a therapy that approximates that for tuberculosis would undoubtedly save much illness and many lives.

Reach Presumptively Tuberculous

Let us use the term "presumptively tuberculous" as expressing that common condition of ill defined lack of health, where the balance between quiescence and activity of infection is adjusted with exquisite delicacy. If then we could drive it home to every physician that he should handle the presumptively tuberculous woman's pregnancy, parturition, and puerperium just a little differently from those of the ordinary woman, or that he should treat the acute infections of all presumptively tuberculous patients a bit more conservatively than is his ordinary habit, there is no doubt that we would contribute much to the reduction of tuberculosis morbidity and mortality. All education of this kind is a highly practical and productive method of combating tuberculosis.

We come now to establish a major premise of the first order, one of such importance that it takes rank with the elimination of public spitting; yet, unlike the latter, it is not directly preventive, but is aimed at the reduction or abolition of morbidity.

This premise is based on three facts, all of which are perfectly well authenticated. They may be stated as follows: (1) infection is almost universal, yet morbidity is relatively very low; (2) a long interval elapses between infection and the manifestations of disease that may result from the infection; and (3) the manifestations of disease are not uncommonly ushered in or precipitated by collateral events in the life of the individual.

In other terms, something besides mere infec-

tion is necessary to the clinical expression of infection. Morbid infection depends not so much upon infection as such as upon non-specific contributory factors. Inasmuch as almost all of us still go about our daily business infected yet healthy people, and because it is tuberculous morbidity that is really responsible for all the evils of tuberculosis,—if in every case infection could be confined it would give us little or no concern,—perhaps our most important practical task is, for the time being at least, to accept infection as part and parcel of the normal make-up of men, and to lay the emphasis on preventing morbidity. In my opinion, so long as the present situation exists, this is the heart of any conceivable progressive program; and I should like to discuss this phase at some length.

Generalization Strictly Scientific

I might begin by reciting list upon list of particular things that make for disease once infection is established: of constitutional defects; of vicious habits; of abnormal customs and modes of living; of social, economic, and industrial conditions; of intercurrent diseases. Such a tabulation in this place would involve only a waste of time. If we are alive to the full significance of all clinical experience, we can at once hew our way through all confusing detail and assert with full assurance that *the contributory factors of tuberculosis morbidity include anything and everything that adversely influence the health of man.* Upon some such broad platform we must take our stand. Some such all-inclusive slogan must be our battle cry. Any less pretentious point of view will not fit the facts. The generalization is strictly scientific. It is certainly more so than to lay a preponderant and almost exclusive emphasis on this or that specific factor, and undoubtedly less likely to create a false perspective and bring on uncomfortable days of reckoning, when, while we do away with one or another contributory factor, tuberculosis still flourishes and the people ask us why.

Along comes someone and tells us, "Tuberculosis is a disease of under-nutrition. Give every man sufficient food and it will disappear." Certainly lack of food may play its part in awakening infection into life; we will grant that much, but when these "one track minds" put side by side columns of diminishing calory figures and increasing tuberculosis statistics they do not prove their case one bit. They seem to forget that there are underlying factors that as a rule make for insufficient feeding,—poverty is surely a most prevalent one,—and that these same underlying factors, poverty again, for instance,

may bring in their train evils of many kinds; improper housing, inadequate clothing, abnormal work and fatigue, unusual exposure to the elements and to every variety of infectious disease. Why then be so cocksure that it is specifically the lack of food that is getting in its work? The same mental antagonism is likely to greet the positive assertion that alcoholism has a direct influence on specific resistance to tuberculous infection: certainly figures that show an unusual amount of consumption among alcoholics do not prove the proposition. Alcoholism presupposes and definitely produces irregularities and exposures of many kinds and it is a most potent breeder of poverty: wherefore, tuberculosis because of alcoholism. But do not expect too much from the abolition of alcoholism unless many other things go with it.

I realize that much of this argument may seem like mere quibbling. But the point I want to make is that we should be very careful not to give the people the wrong impression. By picking out two or three or more superficial concomitants of a high tuberculosis morbidity and hammering away at these with a disregard of the larger field, promising the while vast and mighty results, we are surely getting ourselves into trouble; and, by not getting at the root of the matter, we are not likely to make as much headway against the disease as we might. The people are not likely to be responsive interminably and run from one anti-tuberculosis method to another, while as one becomes disposed of two or more crop up. You know and I know that there are scores and hundreds of determinants of tuberculosis. Then let us carry this news to the people to the point of impressing them with it. Let us, of course, continue our efforts against particular evils; it can be only by paying attention to details that we can affect the mass; but behind and ahead and on all sides of specific measures let us always project the larger vision, —*manifest tuberculosis is due to anything and everything that adversely influences health.*

Cumulation of Non-Specific Factors

If you grant the validity of this statement, it follows with certainty that any fruitful anti-tuberculosis program must involve nothing less than a thorough understanding of what has in general come to be known as public health and an active participation in it. The tuberculosis worker and propagandist can no more stand aloof from all the manifold currents that determine public health than can the public health worker neglect tuberculosis as a prime and almost predominant factor in his field. The tuberculosis

worker who confines his interest and attention to what may be called the specificities of tuberculosis, the tubercle bacillus, its habitats, and its habits, and particular measures directed against it and its effects; and whose eyes are closed or unresponsive to all the non-specific factors,—the inefficient teeth and throats of children, the faulty habits and environment, altogether apart from such things as lunger blocks and dangerous coughers and spitters, of the human being, the excesses of ordinary existence whether they be excesses of labor, of play, or of the passions,—that summon tuberculosis morbidity to the forefront, is not serving his cause well. He is merely pecking away at the flanks and commanding an attack which, no matter how showy and noisy its launching, can lead only to discouragement. He has failed to grasp the location and nature of the enemy's stronghold.

For the center of this whole thing that we call the tuberculosis situation is as fixedly and immutably non-specific as the cause of pathogenic tubercle is specific. Transcendent though the event of the disclosure of the tubercle bacillus was, its results have not been entirely happy. The knowing that there is such a living mite has now and again served us a scurvy trick. It has more than once made of our campaign a mere tournament against the bacillus, while we have forgotten or neglected the fact that morbid tuberculosis, the prevention of disease—of symptoms, of functional disability,—is our real objective. And this thing to be aimed at, this tuberculosis come to light, is in every particular the cumulative result of several or a host of non-specific factors or determinants that have operated for days, for years, aye, even for generations.

In its climb from Lazarus to Dives a family probably does not change greatly so far as concerns the numbers of tubercle bacilli that are embraced from without by the individuals of each generation, but we can predict with more than a little assurance that the incidence of morbid tuberculosis in the family will vary. In like manner it may take a hundred years for Dives of a positive Pirquet test to be brought down to Pirquet-positive Lazarus; and in these hundred years little happens to bacilli, yet much will happen to morbid familial tuberculosis. If you get my meaning you will have grasped the first and central principle of any and every attack on tuberculosis that may convey a promise of success.

As we approach the conclusion of this thesis, let us look this whole thing in the face.

The medical and scientific premises for a successful program against tuberculosis have, with

one or two exceptions, been privileged knowledge for twenty years. I have mentioned only a few of them, a few which I consider of major importance and of a character that invites their practical application. If you expected me to tell you anything new or novel that has emerged from the welter of bed side and laboratory study I am sorry that I have been obliged to disappoint you, for the fact remains that, save for the readjustment and crystallization of our ideas concerning infection and morbidity, nothing of the first importance for our present purpose has been disclosed since 1900.

But the mere statement of a premise is a sorry and unprofitable pastime, and may be a long way from the attainment of conclusion; and it is only by the proper application and working out of premises that proper conclusions may be reached. It is really our business to deal less with the erection of premises and to devote most of our energy to putting them to work. I really am growing a bit weary from observing our professors storm our gatherings with a deluge of papers on early diagnosis, and then go back to their classes and continue to graduate men who know nothing about early diagnosis or just little enough to make them smugly dangerous. There is enough on record about the desirability and necessity of undergraduate instruction in tuberculosis to guide successfully the veriest tyro; yet today in the United States there does not exist a single department of tuberculosis that can adequately instruct all the students of the school. There is to my knowledge not a single first class general hospital that knowingly admits cases of pulmonary tuberculosis to its wards,—“because of the fear of infection,” they say; fit concepts for 1885 or 1890; yet these same hospitals will crowd every type of acute pneumonia and typhoid fever with every variety of acute and infectious disease. You and I contribute to the continuance of dirty milk and promiscuous spitting and inadequate housing, and the social and industrial standards that keep up tuberculous infection and morbidity and which are at the root of these. We either fail to see that, so long as the health of the people is so profoundly depressed by their social environment as it is to-day and always has been, no devotee or practitioner of an improvement in public health can be an advocate or adherent of the social *status quo*; or, seeing this, we do not act because our motives are directed by some to us larger or more personal considerations.

We will get the grip on tuberculosis when we create a universal and correct public sentiment concerning it,—then, and no sooner. Of public health, we may say the same thing. Our task

as professionals in the field is to remain the professionals, yet to become less professional and more human. To attain results, never was an activity in the world quite so much in need of the human touch as is the endeavor to promote the public practice of hygiene. To exhibit pictures of bacteria and cross sections of the human torso and columns of figures to the dweller of the tenement whose belly cries for food and whose eyes are heavy with smoke and dirt is brainless business, busy though we seem to be. To show this man how his surroundings may approximate yours and *to prove to him that you are working with him to make them so* is making progress. The inventor of the glass window probably did more for public hygiene than all the millions of physicians who preceded the period of the invention. Similarly, the man or company of men who can bring about conditions of life that will ameliorate existence to the point of promoting public health will do more good than all pure bacteriologists, pure chemists, and pure statisticians, past, present, and prospective. When we train physicians, we should train men first, and repositories of morbid phenomenology second. When we initiate public health workers into the mysteries of their subject we should develop the sympathies,—that sympathy which Terence has immortalized,—first, and technical aptitude second.

Make Life Less Hazardous

I would not for a moment have you think that I am trying to deprecate study, or the value of study of any kind. I am merely trying to give detached study its proper place in the scheme of things. The study of phenomena will always attract a most unselfish side of man's nature and will enlarge the vision and capabilities of the race. What I have in mind may be stated somewhat as follows: that while much of our knowledge of bacteria must be got together in laboratories and altogether apart from the interests of the crowd, it is on the social mass and largely through and by reason of the character of the social mass that bacteria produce their effects, and that, therefore, in attempting to influence these effects in any far reaching way, we must work from the angle of changing the individual and, therefore, the social point of view.

There is an old saw that nothing is so hard to change as the habits and customs of a people. This may be true; but I have always had a sneaking idea that the maxim was highly debatable unless we introduced the reservation, "provided its environment is not changed." If, therefore, a scheme for the control of tuberculosis that is

based on changing the social point of view were set down as impossible because it premised changes of habits and customs I would refuse to be put out of countenance, for the simple reason that it is environmental change which is the thing we must aim for. We might just as well look at the situation squarely. I think we will all agree that a fixed social environment means a fixed tuberculosis standard. If, therefore, we are to influence tuberculosis we must in some way or other bring about an alteration of social environment; and, as members of any body that is making an attack on tuberculosis, that is exactly what we are here for,—that and nothing else, whether we admit it or not. It is time to change the emphasis which only too long has been laid on the sophomoric and unpleasant, though occasionally necessary, exercise of chasing the "lunger" about the block, to the real work to be done, namely, that of reducing illness by making life less hazardous.

How are we to go about this real work? The sum and substance of our task is that we must carry tuberculosis to the people, to all the people. And we should remember that in so doing we shall be laying before the public practically the entire field of public health. There can be little doubt that tuberculosis is or should be the hub and center of the whole public health movement. There is more than a presumption of plausibility that it should be made the pivot on which almost all good health measures turn. Whatever makes for better conditions as regards tuberculous infection and disease, tends with a very few exceptions to reduce the incidence or deleterious effects of all other diseases. A community of no tuberculosis at once presupposes a community of cleanliness; of temperance and sobriety; of adequate light, space and air, both within and without its habitations, offices and factories; or labor enough for all; of economic and industrial overstrain for none; of opportunities and facilities for the rational employment of leisure; of an intelligent and enlightened medical profession to correct the disabilities of man; of a strong and sympathetic citizenry with an advanced point of view. "Idealistic, Utopian, quixotic, crack-brained," you say; "there is human nature in the way,—egocentric, self-indulgent, prejudiced, uncooperative, etc., etc." Oh, well, maybe so; but take a look down the ages, and perhaps you will find that to-day we are living in a society that was idealistic to the thinkers of Plymouth and Jamestown. Perhaps, too, what is Utopia to us may be the common state of tomorrow. They must be thinking these things right now in your neighboring city of Framingham; and I am sure that, if they

search the depths, they will, when their work is finished, speak to you in a language something like that which I have used above.

Take tuberculosis to the people, and, of necessity, you must preach the doctrine of all good health, and the way to get there, to the people. But when I say the people, I mean *all the people*. For any program to be even measurably successful we must bring about a thorough vulgarization of our knowledge of tuberculosis. The truth must be told and the remedies must be made universally common knowledge. Once appreciation of what is what dawns upon the intelligence of the man of Wall Street, the ranchman of the Texan plain, the Slovak of the coal-breaker, the bent and cross-legged needleman of Hester Street, the people will begin to apply the remedy. If the remedy means the employment of a mechanism through political intervention, let the people take care of this phase. I do not believe that, as public health bodies or officials, we should ever mix actively in political movements, except in a defensive way. If short-sighted, venal, or selfish politicians attempt to undermine ground that has already been gained, then we should fight back and lead the people to the attack; but, to attain reforms that may at any time be non-existent, we should never become involved in all the manipulations, jockeying, and jumbling of issues that characterize the methods of party politics. We dare not court disaster in this way. We must keep our skirts clean; and, with a clear eye, crystallize our objective; and our one and only purpose in propaganda must be to work through publicity for those conditions that mean less tuberculosis. Then, with full knowledge, the people must assume the responsibility of action,—strike where it may. This position and this position only, inasmuch as our status is quasi-public or political, we can defend against all attack.

Publicity and Tuberculosis

Tuberculosis,—public health,—for their programs are identical, must achieve a publicity such as heretofore has probably never even been dreamed of. Our organizations must be enlarged ten and a hundred fold, and in every hamlet the preacher of public health must be as familiar and active a figure as the school teacher, or the friar in the lanes of old Quebec. We must enlist every newspaper syndicate to our cause and have them day in and day out lay the facts of disease and its prevention before their readers. Our leaders in tuberculosis must lay aside their "ethical" scruples, come down to true and effective simples, and become lay preachers through the press; for the time has about arrived when we should take

the writing of newspaper medicine out of the hands of charlatans and of hack writers who have to a certain extent preëmpted the field and who have no nobler motive than self-advertisement or the lust for money.

Misinformation Through the Press

The very fact that every newspaper carries as "feature" matter a "health" column for the instruction and entertainment of its readers shows at once how hungry the people are for information on how to keep well. We all know of what a dubious nature most of this health news now is and what more dubious motives have impelled the writing of all but a small fraction of it. Yet we sit supinely by, behind all the professionalism that hedges what we should be and really is the most humane and most human of activities, and allow this misinformation to go on. We all know how to prevent infection and disease, yet for the most part simply keep telling each other about it, and make but feeble efforts to put this knowledge where it will do the most good, that is, feeble compared to what we could do.

I can go further and affirm that it is probable that the newspaper syndicates would aid wholeheartedly in the right kind of a campaign. In fact, within the last month I have been told by the head of a prominent syndicate that if the right people in tuberculosis were interested, practically all the large syndicates could be got to go before the people with the subject and make it as much a part of their daily lives as any chief topic of the day.

I once more, therefore, come back to the point where I started, the point that I have more than once repeated in this address.

We professionals may know and know things. We may plan and plan and plan things. We may do many things: pasteurize milk here and there; enact laws regarding spitting; here and there invade a home and more or less forcibly make a consumptive conduct himself with some regard to decency and safety; hold exhibitions that reach perhaps 1 per cent of the people and only too many of these already afflicted, and come to learn how they *might have* escaped tuberculosis; provide schools and refuges for consumptives, or imprison them; make early diagnoses; talk about instruction and research, yet fail to endow them. Nearly all of these are based on correct medical and scientific premises and serve a purpose; in specific instances and at specific times they prevent infections and spare from illness and death. But all are merely incidental to a real program against what has become as much an integral part of civilization

as any universal custom or habit. I would repeat that tuberculosis, when associated with the matter of a program against it, cannot be considered apart from the society in which it exists, and its real conquest must originate in the demands of the whole people that it be done away with; and these demands will never be made until everyone appreciates the situation. We may pile premise upon premise, but the task is thankless and wasteful unless we teach and preach incessantly the premise to the world. To do this effectively is our work. Vast and tremendous? Yes; but so is tuberculosis. Impossible? To matter-of-fact minds, to timid natures, to men easily discouraged and of slight tenacity, yes; to romantic and enthusiastic, yet thick skinned individuals, no.

Lead Into Ways of Health

Let me now become really earnest. Pardon the personalness of a confession, if I make one. In this city I sat for five of my best years under Williams and Manatt and Allison and Greene and Mead and Gorham and Tower. I sat at the feet of others, several of whom were like the men I have mentioned by name. These taught, not by rule of thumb, not by the glorification of fact, not by the worship of method and technic. They taught by inspiration. They taught Latin and Greek and German and biology as things that had to do with the living of life, and the spiritual and physical development of man. I remember not a thing of the technicalities of the *Odyssey*; but the place of the Ulyssean character in the world remains ever green in my memory. I can recall but little of what I learned here about the actual anatomy of the frog; but the fact that there is a relationship between the frog and the human being was put to me in a way that I have often profitably dwelt on since.

The years have since taken me into places where my day is largely taken up with instruments of precision and with the controlled exactitudes of phenomena,—with microscopes and test tubes and rabbits and guinea pigs and tubercle bacilli and such things. Little by little my specific function has become that of trying to learn something about the nature of tuberculosis. Once in a great while I think I have learned a new fact; and then with full force there surges the query, "What is its place in the larger field, in the conquest of consumption?" "The conquest of consumption,"—a subject that engages much of my thoughts; and, whenever I brood over it, after all the fringes have been cut away, as the matter seems to take shape and stand out in the fog, I always find myself thinking in terms like these: —If I had my way, if I could so order it, I should

call to me my best and most sympathetic students. And I should say, "Here are the facts, —the premises. We have found them out here; but, confined here, they are useless. Go now out into the world and lay them before the people. Go not as Republicans or Democrats, not as individualists or communists, not as scientists or physicians. Go as *men* with a theme to teach and preach. Go with only one idea, and let this idea be the leading of man into the ways of health. Let the method be one of persuasion. Point out the things that man must do to achieve freedom from disease; and in this demonstration let nothing deter or divert you. Follow the trail wherever it may lead; and be not fearful of the consequences. You have only one responsibility, and this is the achievement of better health for man; and in this, the holiest, most unselfish, and most blessed cause that a human being can enlist in, you need suffer no misgiving concerning anything else that may occur in or because of the process of achievement."

PUBLIC HEALTH ASSOCIATION URGES EXTENSION OF MEDICAL SERVICE

Among the resolutions of most significance adopted by the American Public Health Association at its Forty-seventh Annual Meeting in New Orleans recently, were those urging the enactment of legislation under which provisions may be made for the correction of remedial physical defects by physical training; urging the appointment of committees in the several countries represented in the Association by their Federal Governments to study existing methods for preservation and improvement of the health of the people, such as hospital facilities, public health activities, charitable institutions, and compulsory health insurance, with a view to reporting some adequate plan for coordinating already existing activities and for extending the application of scientific and social agencies for accomplishing the desired ends; favoring legislation for increased compensation for officers in the United States Public Health Service; urging that a national medical examination week be appointed during the month of May, 1920, with a view to arousing the people to the necessity for periodical physical examinations; recommending that measures should be taken to assure for the future a National Health Program and a coordinated Federal health administration, and commanding the work of the United States Army and Navy in combating venereal diseases during the period of the war, and offering the active cooperation of the Association officers, members, and Committee on Venereal Diseases in promoting the Federal campaign against these diseases.

The officers elected for the coming year are: President, Dr. W. S. Rankin, secretary North Carolina State Board of Health, Raleigh, N. C.; vice-presidents, John Armyot, head of Canadian National Health Service, Ottawa, Canada; William H. Robin, superintendent, City Board of Health, New Orleans, La.; G. H. Sumner, retiring treasurer, Des Moines, Ia.; secretary, W. H. Hedrick, secretary American Public Health Association, Boston; treasurer, Lee K. Frankel, retiring president American Public Health Association, New York.

A "COME CLEAN" LECTURE

ONE of the features presented before the meeting of the American Public Health Association in October which is unusually well calculated to carry the message intended was the "Come Clean" lecture by Maj. Leonard G. Mitchell, D.C., U.S.A., a summary of which is made in this report. Disease prevention through the proper care of the teeth is urged in this lecture, illustrated by a three reel picture designed to teach oral hygiene. The picture is the outgrowth of oral hygiene lectures delivered to the officers and men at the Army Medical Museum.

A Dramatic Story

Private Tom Merrill as the center of the picture is being ridiculed for brushing his teeth. Some of his buddies hide his brush, and a fistic encounter results after which Tom explains why he takes such good care of his teeth. Views of several wards at Walter Reed Hospital are shown, including cases of joint arthritis with swollen joints, heart disease, and appendicitis with complications, growing out of neglect of teeth.

The picture then takes up the scientific part, showing how and why infection from pyorrhea and abscessed teeth reaches and infects various parts of the body, producing various diseases, the infection being shown on its way by the use of animated drawings.

Surgeon General Ireland and chiefs of various sections of the Army Medical Department witnessed the first showing of this picture and it carries their hearty endorsement. Copies of the films will be sent to camps and be made available for organizations desiring to use them in campaigns for the care of the teeth.

Strength the Objective

"The United States Government, through various departments, is now in the midst of a nationwide campaign of education, the purpose and scope of which is rehabilitation and reconstruction in several lines of endeavor to the end that we may become a more virile and stronger people. This campaign surpasses any like effort in the history of our Country, not even excepting the days following the Civil War. Our part in this great work is the conserving of health by combating preventable diseases; for good health is the logical and natural foundation upon which we may hope to erect the superstructure of contentment, happiness, prosperity, and natural greatness.

"The Surgeon General of the Army, and an in-

creasingly large number of America's leading surgeons, pathologists, and research men now recognize the diseased mouth and teeth as causative factors of many of the serious diseases of the body.

"When a subject, such as mouth hygiene, is presented for our consideration, overthrowing our preconceived ideas, conflicting with custom, or doing violence to our early teaching, or the lack of it, we are conscious of a certain degree of opposition, which is based upon a prejudice due to a lack of knowledge of the subject, or a general apathy. It is well, therefore, to state at the outset that we are now dealing with one of the most serious problems which confront the American people today—the unclean and diseased mouth in its relation to these systemic diseases. The three-reel picture we are about to show was made at the Army Medical Museum by direction of the Surgeon General of the Army, with a view of impressing upon the minds of our soldiers the very great importance of freeing the mouth of all infection and maintaining strict mouth hygiene. (Picture shown here.)

"It is quite impossible to show clearly and adequately in the picture all you should know about mouth hygiene; we will, therefore, briefly enlarge upon and emphasize a few of the more important features in order that you may appreciate their importance.

Causes of Constricted Arches

"The very early training of children must not be neglected, if they are to have strong teeth and good health. Thumb-sucking and the use of a pacifier can not be too strongly condemned as they cause constriction of the arches and nasal passages, resulting in mouth breathing, adenoids, enlarged tonsils, and irregular teeth, with their long train of systemic ills which will materially affect the general health and life of the individual.

"The deciduous, or first teeth, must be saved until the normal time for them to be replaced by the permanent teeth. These first teeth provide the required development of the jaws for the permanent teeth, thus preventing irregularity of the permanent teeth. The first teeth also guide the permanent teeth into their proper alignment and position.

"The first permanent molars, which erupt at the age of six, are the most important of all the permanent teeth, yet are the most neglected. The loss of one or more of these teeth means loss of

normal occlusion, inability to chew properly; the tipping into the space of the second molar, especially when the third molars, or wisdom teeth, erupt. This condition is also responsible for pyorrhea later in life.

Give Teeth Some Work to Do

"Children should have plenty of coarse food which requires much chewing; also food, such as milk and eggs, which contains plenty of lime. The teeth and surrounding tissues require exercise the same as other parts of the body.

"The picture quite clearly shows the formation of a cavity and how, if neglected, the nerve becomes involved, and an abscess forms; also how various parts of the body of the individual are reached and become diseased; but it does not sufficiently emphasize the danger of the so-called blind abscess. By this we mean the abscess which does not open through the gum to the surface or cause pain. This form of abscess will occur when the dental pulp or "nerve" has been removed and the canal imperfectly filled. The formation of pus in such an abscess is so slow that the blood circulation can absorb it and it is carried to all parts of the body, producing no swelling of the gum or pain about the tooth. In fact, this tooth may do its work year after year without pain or inconvenience to the individual, yet establish a serious infection in some remote part of the body, as shown in the picture. This process being painless, it is insidious and, therefore, dangerous.

The X-Ray an Adjunct

"The x-ray is proving that a very small per cent of root canals are properly filled when the nerve is removed from a diseased tooth. Indeed, so small a percentage is it that we are ashamed to tell you. However, it prompts us to say in all seriousness, if you have a tooth from which the nerve has been removed, you should by all means, have that tooth x-rayed and see for yourself that the canals are well filled and that there is no infection.

"A dentist can no more do root-canal work without the use of an x-ray equipment than can a physician successfully combat a fever without the use of a thermometer. At Walter Reed Hospital, Washington, D. C., where several of these scenes were taken, there are on record many cases where these blind abscesses, resulting from poorly filled root canals, have been the cause of serious diseases of the body.

"Concerning pyorrhea, very little need be added to what you have seen on the screen except to say that this dread disease is one of the most common and the most destructive that we have to fight.

Its causes are many. Among the most common causes we find: lack of cleanliness, food deposits allowed to accumulate and decompose about and between the teeth; lime salts allowed to accumulate; poorly constructed crown and bridge work, so food deposits may find lodgment under the edge of the crown or bridge where the brush can not reach it; irregular and malposed teeth, due to early loss of teeth; poor occlusion with opposite teeth, etc.

"The loss of teeth from pyorrhea is a serious one. The bone-process is so destroyed that there is little left to hold plates; therefore, it is quite impossible properly to masticate food. We exert a stress of from 100 to 300 pounds in ordinary chewing with our natural teeth, while with well-fitting plates the stress is but 50 pounds. If Nature designed our chewing mechanism for a stress of 500 pounds, how can we prepare our food for assimilation with a stress of but 50 pounds? This abnormal tax on our digestive system must make serious inroads on our vitality. However, it is infinitely better to go without teeth and without plates, if necessary, rather than retain diseased teeth if the pyorrhea is beyond curing.

Cure by Cleanliness

"Pyorrhea can be cured and it will stay cured if treated in time and the teeth are kept clean. But remember this: the tissue Nature builds up in these pockets where the bone has been destroyed is not as dense as was the original bone structure; therefore, what caused the disease in the first instance will bring about its return easier than it originally caused it.

"In the light of modern scientific research we must take cognizance of these established facts. Our people must be taught right and proper methods of living if we are to increase the general efficiency of the race and render coming generations more impregnable to disease. Our state legislatures should provide adequate protection for society against incompetent and unscrupulous dentists so that a license to practise is evidence to the public of efficiency, skill, and honesty. The physical welfare of the people should take precedence over all other matters. When the people demand this protection it will be granted."

Clinical Congress Elects

The Clinical Congress at its annual meeting October 23, chose the following officers for the coming year: president, Dr. George E. Armstrong, Montreal; vice-presidents, Dr. Rudolph Matas, New Orleans, and Horace Packard, Boston; regents for term expiring in 1921, Dr. Alexander Primrose, Toronto; Albert J. Ochsner, Chicago; George W. Crile, Cleveland; Harvey Cushing, Boston; George L.

de Schweinitz, Bethlehem, Pa.; and William J. Mayo, Rochester, Minn.; for the term expiring in 1922, Dr. John M. T. Finney, Baltimore; James B. Eagleson, Seattle; Charles H. Mayo, Rochester, Minn.; J. Bentley Squier, New York; Dr. Walter W. Chipman, Montreal.

SCHOOL MEDICAL INSPECTION

BY TALIAFERRO CLARK, Assistant Surgeon General, United States Public Health Service*

It is very desirable that communities, and especially the responsible officials, should take stock of resources for the health supervision of school children. Owing to inevitable adjustments that are now taking place in the national life as a result of the war, and especially in view of the changed economic conditions, the increased cost of the necessities of life, and the strong appeal of greater remuneration in other fields to those engaged in health activities, the importance of adequate health supervision of the children of the land is emphasized as never before in the history of our country.

Advantages of Health Supervision

The health of the growing child determines largely the health and bodily vigor of the grown man. The community, therefore, can take no more important step to insure the future efficiency of its citizens than that of growing healthy children. In the present state of society an intelligent supervision of the health of the children during the period of school life is probably one of the most potent measures for this purpose and is recognized as such by law in an increasing number of the states of the Union. This is especially true since in but a very few fortunate communities is any attention whatsoever given to general health supervision of children during the impressionable pre-school age covering the period from two to five years of age, inclusive.

Intensive studies of the physical conditions of children in many places have shown large numbers of them to have physical defects which were previously unrecognized and unsuspected. Many of the defects thus shown are preventable and remediable. Their persistence results not only in reduced individual efficiency, but also, in the aggregate, in reduced national efficiency, as is so clearly shown by the high percentage of those found unfit for military service in the physical examinations conducted under the selective service law.

The conditions under which children assemble in school, and not the school itself, are largely responsible for much of the sickness contracted during the period of school life and for the persistence of physical defects. The control of adverse causes during this period not only exercises an immediate beneficial effect on the health of the children, but serves most effectively to teach them the principles of personal hygiene, the non-observance of which is now believed to be mainly responsible for the large annual increase in the number of deaths from degenerative diseases that occur later in life.

Experience shows that the failure to prevent and correct impairment of hearing and vision and to detect abnormalities of color perception, to secure dental attention, to alleviate postural defects, to place the normal child in an environment best suited for physical development, greatly restricts the range of industrial, business, and professional opportunity in adult life. Moreover, a number of defective children are unable to take full advantage of their educational opportunity. They fall behind in

school work, become discouraged because unable to keep pace with normal children in their classes, and ultimately quit school poorly prepared for useful citizenship. It is of prime importance to the community, therefore, to take cognizance of these possibilities in order that steps may be taken to prevent them. Furthermore, the control of the communicable diseases in the community can be accomplished more effectively when undertaken in connection with the medical inspection of school children. Altogether, the loss of life, the impairment of hearing and vision, the tendency to degenerative diseases caused by neglect of personal hygiene, and the loss of time in school work render it highly desirable from the economic standpoint alone to inaugurate a measure so potential in the control of the communicable diseases.

System of Health Supervision

An effective system of health supervision of school children should provide (1) for the thorough sanitation of all buildings used for school purposes; (2) for the intelligent supervision of classrooms to detect and correct con-

Fig. 1. This decorated float which appeared in a parade on Commencement Day at Kinston, N. C., formed a novel advertisement of the benefits to be derived from Health Inspection.

ditions injurious to the health of the pupils as soon as they arise; (3) for the full-time services of medical inspectors qualified to discharge the sanitary and medical duties of the school physicians; (4) for the full-time services of school nurses; (5) for facilities for dental inspections; (6) provisions whereby necessitous children may receive free treatment best suited to their needs; and (7) for a thorough mental examination of all children who fail to progress normally in schoolwork. Objections have been made to health supervision of school children and the treatment of their physical defects on the ground that such measures discriminate against the regular practice of medicine, encourage pauperism in parents, raise the tax rate, and tend to bring about a lowered sense of responsibility on the part of parents in respect to the health of their children. The experience of countries and communities wherein these measures are in full force does not substantiate these claims. It has been found that the more regular attendance of children at school brought about by competent health supervision, and the educational effect on parents of such measures when applied to their children, reflect in time so advantageously on the community as to more than compensate for the expenditures involved in such supervision.

The demands of a reasonable medical inspection of school children are met by the following observances: (1) to examine for the presence of physical or mental defects which make it inadvisable for certain children to attend

*Reprint from the Public Health Reports, XXXIV, No. 36, Sept. 5, 1919, 2013.

school; (2) to measure and weigh all children to determine the average physical development by sex and one-year age periods, and the utilization of such standards as an index of nutrition and as a guide to the discovery of harmful causes in the case of children who do not develop normally; (3) to discover, remove, and prevent defects of dentition, hearing, posture, and vision that hamper children in schoolwork and retard their physical and mental development; (4) to aid the health authorities in the control of communicable diseases.

Requirements of Medical Inspector

The minimum requirements of an acceptable school physician are: (1) that he should devote his full time to the supervision of the health of school children; (2) that he should be skilled in medical diagnosis, able to advise with and assist the family physician when it is so desired; (3) that he should have a knowledge of bacteriology sufficient to enable him to take cultures, detect "carriers," and otherwise assist the health authorities so that it may be unnecessary to close schools during epidemics of communicable diseases; (4) that he should be well grounded in the principles of personal and general hygiene, and have the ability to apply them to school purposes; (5) that he should be competent to prescribe suitable exercises in individual cases to overcome postural defects, and advise with regard to regulated group exercises designed to promote the best physical development of normal children; (6) and that he should notify all parents of the presence of physical defects in their children as soon as these defects are discovered and make reasonable efforts to have his recommendations carried out.

In the selection of a school physician due regard should be given to his ability to direct the seating of children, to make observation of atmospheric conditions in class-

rooms, to measure illumination and to advise in regard to changes necessary to secure the maximum of illumination with the minimum of visual discomfort, and finally to advise janitors in respect to the heating and ventilation of school buildings.

Private Practice Interferes

The employment of a physician engaged in private practice to devote a part of his time to the medical inspection of school children is not productive of good results. On the average it requires the full time of a specially qualified physician to supervise effectively the health of 2,000 school children. Furthermore, the employment of a practising physician for this purpose is frequently the cause of jealousy and opposition on the part of other local practitioners that negative the efforts of the school physician.

One of the great drawbacks to the employment of a school physician heretofore has been the apparent unwillingness of the school and health authorities to recognize and clearly to define their duty in respect to school health supervision. Fundamentally, the duty of the school organization is to impart instruction, and this should include instruction in health through courses in personal and general hygiene adapted to the needs of various age-groups and by the organization of classes in physical training.

On the other hand, the function of the health department is preventive and corrective, and as applied to school health supervision should include the medical examination of the children for the detection and removal of the hampering physical defects and for the control of communicable diseases, as well as supervision of the sanitation of the school buildings and grounds and playgrounds. In fact, the measure of the mental and physical efficiency of the children of a community will be largely proportional

A school much above the average rural school of Tennessee.

Types which indicate degrees of under nourishment.

Fig. 2. The nurse has just finished the physical examination and the dentist has completed free dental treatment for these groups of Pender County school children. Both nurse and dentist were sent out free by the Department of Medical Inspection of Schools of the North Carolina Board of Health.

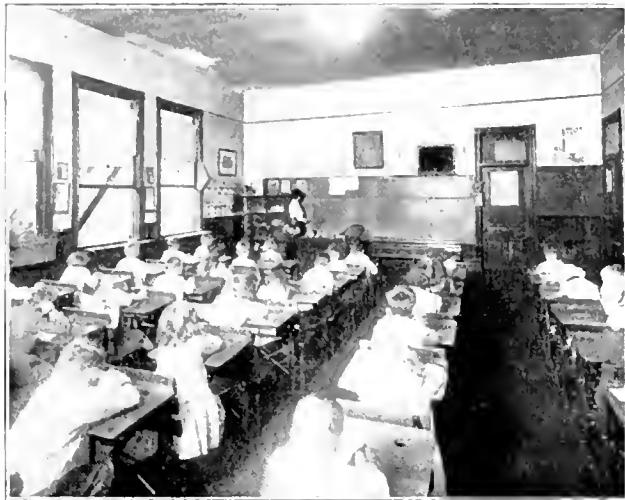

Fig. 3. The interior of a school room as it appears to the child with normal vision. Proper health supervision which would include examination of the eyes would demonstrate whether or not each pupil sees each detail clearly, or whether it appears to some as in Fig. 4.

to the completeness of the cooperation of the two responsible agencies in this work.

Dental Attention

Dental defects constitute the most numerous of all defects found during medical inspection. The percentage of children in need of attention to the teeth is highest among those from five to eight years of age, the percentage gradually decreasing in successive older age-groups. It is now recognized quite generally by the medical and dental professions that defective teeth are responsible for serious disturbances of the general health. Especially is this true of "rheumatic" affections, heart disease, and gastric disturbances. No system of health supervision of children can be thoroughly effective, therefore, that does not secure correction of dental defects or fails to instruct parents in dental prophylaxis.

All children should be encouraged to visit the school dentist as he is employed for their especial benefit. The time will come when the school dentist will be considered just as necessary a part of the school system as the school principal himself.

In school dental work, if it is ever impossible to care for all the teeth of all the children, the teeth of the children in the first two or three grades should receive attention first, and thus after awhile the task will have been accomplished for all children.

Duties of the School Nurse

The school nurse should be directly responsible to the school physician for the proper discharge of her duties. Her activities should supplement those of the school physician and correlate with them. She should have sufficient training to carry out the routine treatment of minor ailments in necessitous children under supervision of the school physician; she should be required to visit the parents of ailing children, when necessary, to instruct them in the care of the sick and in the prevention of disease; she should "follow up" children recommended for treatment by the school physician to induce parents to carry out his recommendations in case of their failure to do so; she should from time to time visit children who have been excluded from school for purposes of treatment, to insure their return without undue loss of time; she should be required to visit children absent from school for three successive days from unexplained causes, and

in case of sickness make inquiry as to its nature in order to guard against communicable diseases. She should report the results of follow-up work to the school physician so that they may be properly recorded.

The importance of home visitation can not be too strongly emphasized, and the absence of such visitation interferes greatly with the efficiency of the agencies which look after children. When an inexperienced mother tries to carry out at home the advice she has been given, she frequently finds that she has either forgotten, or has imperfectly understood the directions, or she meets with an unanticipated difficulty which she does not know how to overcome.

The services of the school nurse may be advantageously used during the vacation period in infant welfare work, or in some other form of community health supervision.

Recording Results of Medical Inspection

Every child should be subjected to a rigid medical examination as soon as possible after first entering school. The results of such examination should be card indexed and filed in such manner as to be instantly available for reference. Immediately following the examination, the parents of the child should be notified, in writing, of the presence of physical conditions which require medical or surgical attention. Such notification should be supplemented by visits from the school nurse, and neglectful parents should be advised of the necessity for such attention.

The form used for recording physical defects and other information regarding the school children should be arranged to suit the demands of local conditions. In general, such cards should show the name and address of the child, the name and address of parents or guardian, the exact date of birth, the sex and nationality of the child, the height and weight, the physical defects at the time of the examination, and such other information as may be useful. The subject matter should be so arranged as to provide space for recording the results of reexaminations in succeeding years. Such cards should also indicate the treatment advised, the results of treatment, and the subsequent disposition of each particular case.

Dental defects should be recorded on a card of the same size as the medical-inspection card, and filed with it. Such cards may be conveniently arranged showing cuts of the

Fig. 4. Many pupils are considered dull in school when properly fitted glasses are all that are necessary to make them rival the brightest. How can one do a sum in arithmetic when the blackboard on which it is written looks like a fog bank and the figures themselves are invisible?

temporary and permanent teeth, with spaces for recording the results of dental inspections and treatment.

The notification blank to parent or guardian may be arranged as follows:

OFFICE MEDICAL INSPECTOR OF SCHOOLS

Parent or guardian..... Address.....
 A recent physical inspection of..... Name of child.....
 attending the..... indicates the following
 Name of school..... abnormal conditions:
 You are advised to take..... Name of child.....
 family physician, dentist, oculist, or to a dispensary for advice
 and treatment.....
 Medical inspector.....

In every case where the child is excluded from school on account of sickness or disability, the medical inspector should be required to notify, in writing, the parent or guardian, specifying the cause of such exclusion and stating explicitly the terms under which the child may return to school.

AN APPEAL FOR HUMAN EMBRYOLOGICAL MATERIAL

BY WILLIAM W. GRAVES, ST. LOUIS

In 1906 I observed certain malformations of the human shoulder-blade, and in contributions to current literature I have given them the collective name, "the scaphoid type of scapula," and pointed out some of its hereditary, clinical and anatomical significance.

Probably the most important observation connected with this type of scapula in man is its age incidence, that is to say, it occurs with great frequency among the young and with relative infrequency among the old. There appear to be two possible explanations of this fact: either (1) one form of shoulder-blade changes into the other during development and growth; or (2) many of the possessors of the scaphoid type of scapula are the poorly adaptable, the peculiarly vulnerable, the unduly disease susceptible,—the inherently weakened of the race.

I have attempted to answer these questions by seeking evidence in various directions and one of the most important of these has been a study of intra-uterine development of shoulder blades. My investigations in this direction have been limited by the material at my disposal, which has been inadequate for a definite solution of this phase of the problem. I am, therefore, appealing to physicians for fetuses in any and all stages of human development.

It is desired that the material, as soon as possible after delivery, be immersed in 10 per cent formalin in a sealed container, and be forwarded to my address; Metropolitan building, charges collect. Due acknowledgment will be made to those forwarding material.

INCREASED FUNDS FOR RESEARCH

The Rockefeller Institute for Medical Research announces an added gift of \$10,000,000 by John D. Rockefeller, making a recent acquisition of \$30,000,000 for the spread of medical education. This fund will not materially enlarge the scope of activities, but covers increased costs which meant either additional endowment, or a curtailment of activities.

AMERICAN PUBLIC HEALTH ASSOCIATION ELECTS RANKIN PRESIDENT

WILLIAM S. RANKIN, president, American Public Health Association.

Watson Smith Rankin, recently elected president of the American Public Health Association, is a specialist in public health work. He was born in Mooresville, N. C., in 1879, and attended the high schools of this town and Statesville, N. C., prior to taking up the study of medicine at the North Carolina Medical College, Davidson College, and the Medical College of the University of Maryland.

Following his graduation, he served as intern in the University of Maryland Hospital for eighteen months, afterwards taking a year's postgraduate work at the Johns Hopkins Medical School. Upon completing his postgraduate work, he spent six months as resident physician in the Obstetrical Hospital of the University of Maryland. During the succeeding thirteen months he served as resident pathologist in the University Hospital at Baltimore. For a time he was pathologist in the Medical Department of Wake Forest College, Wake Forest, N. C., and from 1905 until 1909 acted as dean of its School of Medicine. Doctor Rankin is a Trustee of the Wake Forest College and of the North Carolina Sanatorium for the Prevention of Tuberculosis. He is secretary of the North Carolina State Board of Health, and a member of several medical societies.

PROBLEMS IN SOCIAL MEDICINE

Medical and Health Education, Child Welfare, Social Insurance, Rehabilitation, Medical Law and Allied Subjects

JOHN A. LAPP, LL.D., Editor

SOME LATENT CAUSES OF RACE DEGENERATION

IT was an unostentatious malady [malaria] which dimmed the blaze of glory that shone around early Greece, until it faded away into the dark degradation of Hellenistic times.¹

The change in the character of the Greek and of the Roman peoples had commenced long before the culminating disasters which led to the destruction of classical civilization. It was, if felt at all, but vaguely realized. The cause was not even suspected.

Should we not ask ourselves whether in our time there is no insidious agent at work which, given time and unchecked course, may lead to degeneration of our race? Our inquiries would take two directions. First, do we know of any relatively new or increasingly frequent disease which might have such an effect? Second, are there any signs of such an action?

In answer to the first question, it is certain that syphilis will come first to the mind. It is comparatively new; it was insidious. Syphilis is now, however, out of the insidious class. We can fight it in the open. We know its cause; we possess remedies of considerable specificity and potency; we are at last allowed to speak frankly to the public on the subject. Whatever in the past has been the effect on the race of syphilitic infection, we have good reason to believe that much of its power for generalized evil will disappear in the near future.

But what of influenza? Our attention is more liable to be attracted to the striking dangers of its acute manifestations. Do we know that it leaves no disability behind?

The febrile attacks of malaria, the secondary rashes and tertiary gummatous of syphilis fixed the attention more than the cachexia and the temper-

amental changes due to chronic paludism, in the one case, and the remote nervous and mental lesions of the other.

We do not know, *pace* some bacteriologists, the cause of influenza. We have no accepted specific treatment.

Some historians affirm the existence of a physiological change in the race, occurring gradually in the early nineteenth century, a change involving greater irritability, leading to social unrest. Even the ability of our near ancestors to be three-bottle men, and to transact their business, and live to a hale old age, according to these authorities, has been lost; and the loss, they would have us believe, is one of the signs of a racial degeneration. However, this may be, we may well ask ourselves the questions:

Are our adults more irritable, less tolerant, and shorter lived, more subject to diseases of degeneration, than their forbears? If so, do the recurring epidemics of influenza have any share in the production of this condition?

MIDWIVES

SOME valuable discussions of the problem of midwives have been given to the public during the last few weeks. One of these is from a report by Dr. Chas. E. Terry, on sanitary and health conditions in Wilmington, in which he deals to some extent with the problem of regulating the midwives in that city. After stating the fact that the practice of midwives is general and is not adequately regulated, Doctor Terry puts the case thus:

If a physician from another state, although a graduate in medicine, and possibly highly skilled in his profession, should enter the state of Delaware and attempt to practise medicine, without first securing a license from the State Board of Medical Examiners, he would be prosecuted, and rightly so, even though he confined his practice to obstetrics. Any ignorant woman, however, of the

1. Jones, W. H. S., Malaria and Greek History.

type above described, has only to style herself a midwife to be permitted to assume the responsibility of life and death in the practice of one of the most complicated and difficult branches of medicine. It should be remembered that, while we are accustomed to consider childbirth a physiologic process, yet nothing in the field of medicine or surgery presents, at times, such perilous situations as are encountered in the practice of obstetrics,—situations wherein the utmost skill and the most expert judgment are required and wherein ignorance, neglect, or carelessness, may cause the loss of two lives.

After citing the dangerous practices which were found to exist, he says:

Many of the customs and practices of these women will not bear repeating and all of them would be ridiculous, were they not potential for such tragic effects on mothers and babies. Not a single one of the midwives visited showed the slightest conception of surgical cleanliness, so important in the prevention of childbed fever.

The remedy for the situation disclosed he suggests is to require midwives to register and to show sufficient elementary knowledge to fit them for their calling.

He urges further that they be forbidden to make certain examinations, and be required to call a physician in every complicated case. Further-

more, he recommends that every case of child-birth attended by a midwife should be visited by a trained public health nurse within twenty-four or forty-eight hours.

The second discussion which recently appeared, is found in "Standards of Child Welfare" issued by the Children's Bureau, in an address by Dr. Chas. V. Chapin, of Providence, R. I. After broadly treating the subject, Doctor Chapin points out the following conclusions applicable chiefly to cities with large foreign populations:

- (1) The midwife is unnecessary and can gradually be eliminated.
- (2) There should be an annual registration, and supervision should be maintained.
- (3) The foreign population must be educated, the most valuable agencies being nurses and clinics.
- (4) Prenatal clinics are needed and especially an enlarged out-patient obstetric service, partly free and partly pay.
- (5) More maternity wards are needed.
- (6) There should be better obstetric training for medical students, which will be made possible by greater opportunity for clinical instruction.

AN IOWA ENTERPRISE IN MEDICAL SERVICE

BY A. E. KEPFORD, DEPARTMENT OF TUBERCULOSIS, BOARD OF STATE INSTITUTIONS, DES MOINES, IOWA

IT is difficult to put down in cold type a great inspiration. It is like trying to photograph a beautiful face in which one desires to reproduce spiritual qualities. The only thing one can do is to get a delineation of the face in which the deeper meanings of character are not revealed. The same difficulty is faced in any attempt to describe adequately the inception and organization of the Greater Community Association of Creston, Iowa, which is at once a plan and a prophecy and which involves the highest principles of democracy.

Dr. F. E. Sampson, a physician and surgeon of Creston, Iowa, may be called the prophet of this great movement; he has led the way to the promotion of the Greater Community Association by which six counties have organized their social, religious, educational, and economic forces. Through his long experience he had witnessed thousands of men and women who were the victims of social ignorance and neglect coming to the hospital for surgical and other care. This appalling waste of physical resources, much of which could have been prevented, made a dramatic appeal to him. Many of the persons who sought relief were the victims of a system of medical and social procedure in which society had made the fundamental mistake of failing to recognize and remove the causes which produce these unfortu-

nate effects. Attempts at hospitalization are often only perfunctory because of the lack of adequate equipment and the scientific training which is necessary if persons seeking relief are to be cared for properly. In other words, many hospitals are but a step removed from ordinary boarding houses and, through insufficient financial or other support, possess but limited opportunities to become efficient. And then, too, there are those petty and irritating misunderstandings in the community, not only civic but medical, which prevent the highest interest of the patient being al-

Fig. 1. The rented cottage where Cottage Hospital began October 1, 1894, with a few pieces of white enameled furniture, including five beds and an operating table; working force of one nurse, one cook, one chambermaid; and the notion that these justified calling the place a hospital.

ways taken into consideration. Superstition and suspicion are the results of ignorance; tragedies arise from the fact that people do not know each other well enough. Generally speaking, people desire to do what is right, but through lack of knowledge, organization, and coordinated effort they can not accomplish the things which are for the best interests of the whole neighborhood. As a rule, people are kind-hearted and deeply interested in community welfare, and there is always an avenue of approach open to those who seek the public good.

Dr. Sampson sensed this. He saw the human possibilities. He has an abiding faith in humanity. He has a very deep reverence for the genuis of Christianity. The greater community association of his vision was to be a correlated expression of the social forces of a population of over a hundred thousand souls.

In ancient times the physician was also the priest. Medicine and religion are and always will be coordinate. The healing of the souls of men has a close relation to physical welfare, though this fact has not been recognized by the church. There can be no permanent separation between the spirit and the body in the present order of things. They are coexistent and interdependent. That which makes for physical welfare has always its moral reflex action on the soul. The church is part of the very foundation of the Greater Community Association. It is permanent. Men die, but man lives, and, so long as man exists as man, instinct will group men for spiritual enterprise.

The medical profession is also a fundamental group upon which the Greater Community Association is built. As the nineteenth century was the era of discovery and invention in which equipment was assembled, so the twentieth century is the era of prevention. The achievements of medical science in both civil and military affairs proclaim its right to leadership in public welfare.

Completing the triangular foundation upon which the Greater Community Association rests is the educational group comprising public, private, and parochial schools. Secondary to these primary divisions are the economic and civil groups. The completed scheme, therefore, includes churches, lodges, schools, commercial clubs, women's clubs, city councils, boards of supervisors, medical societies, and any other form of social or economic organization throughout the area.

Prevention is better than cure. In fact, prevention is more easily accomplished than cure. To prevent disease, delinquency, and crime is the social gospel of the twentieth century. What multitudes of human beings may be seen today socially, morally, and economically unfit, loading the

Fig. 2. Cottage Hospital as it appeared on its twenty-fourth anniversary of continuous service. On January 1, 1919, it was transferred to the Greater Community Association, and its name changed to the "Greater Community Hospital." The south wing is to have one more floor, and a solarium will be built upon the roof. The Spaulding Service Building to the rear of the fourth story of the central building does not show in the picture.

ship of state down to the very water line, who through proper social cooperation could have been kept fit and at a high point of civic efficiency! It is not to be wondered at that the Greater Community Association puts its emphasis on child welfare. It makes provision for the adequate physical and mental care of children. It proposes to establish child welfare stations and psychopathic and tuberculosis clinics accessible to every child in the various communities throughout the countryside.

This preventive work will be directed by a social service secretary, who will not only supervise a staff of nurses doing extension work along this line, but who will also help to solve the social problems growing out of such nursing service.

This plan might appear to be the fabric of a beautiful dream but for the fact that a very material foundation has been laid, upon which this entire social structure has been erected. That foundation is a hospital located in the city of Creston, which represents an investment in grounds, buildings, and equipment of over \$100,000. It has had a successful existence of twenty-five years. This hospital has been donated as a free gift to the Greater Community Association and is now a hospital belonging to a population of over a hundred thousand people. It is the people's hospital and stands without incumbrance, a monument to the faith of those who devised and promoted the Greater Community Association.

The hospital belongs to and is controlled by the people. It does not exist for any physician or group of physicians. The motto of the Greater Community Association is "Service." The hospital affords no special privileges to any physician. It does, however, offer multitudes of opportunities to every visioned doctor. The hospital stands as a challenge to the genuis, ability, and energy of every medical man in the area. Its

hospitable doors are wide open to every physician who can prove his worthiness to enter. The Greater Community Association says: "Here is the equipment. Here is an x-ray equipment and an expert roentgenologist. Here are the laboratories. Here is a nursing service, second to none. Here is your community. But you must prove worthy to serve your own community in your own

are the precept that it shall be a long way from the threshold of the hospital to the operating room and the rule that from the time a patient enters the hospital a complete record of his case is kept. There can be no dark and sinister compacts here between physician and patient.

The government of the Greater Community Association is vested in a board of governors. (See

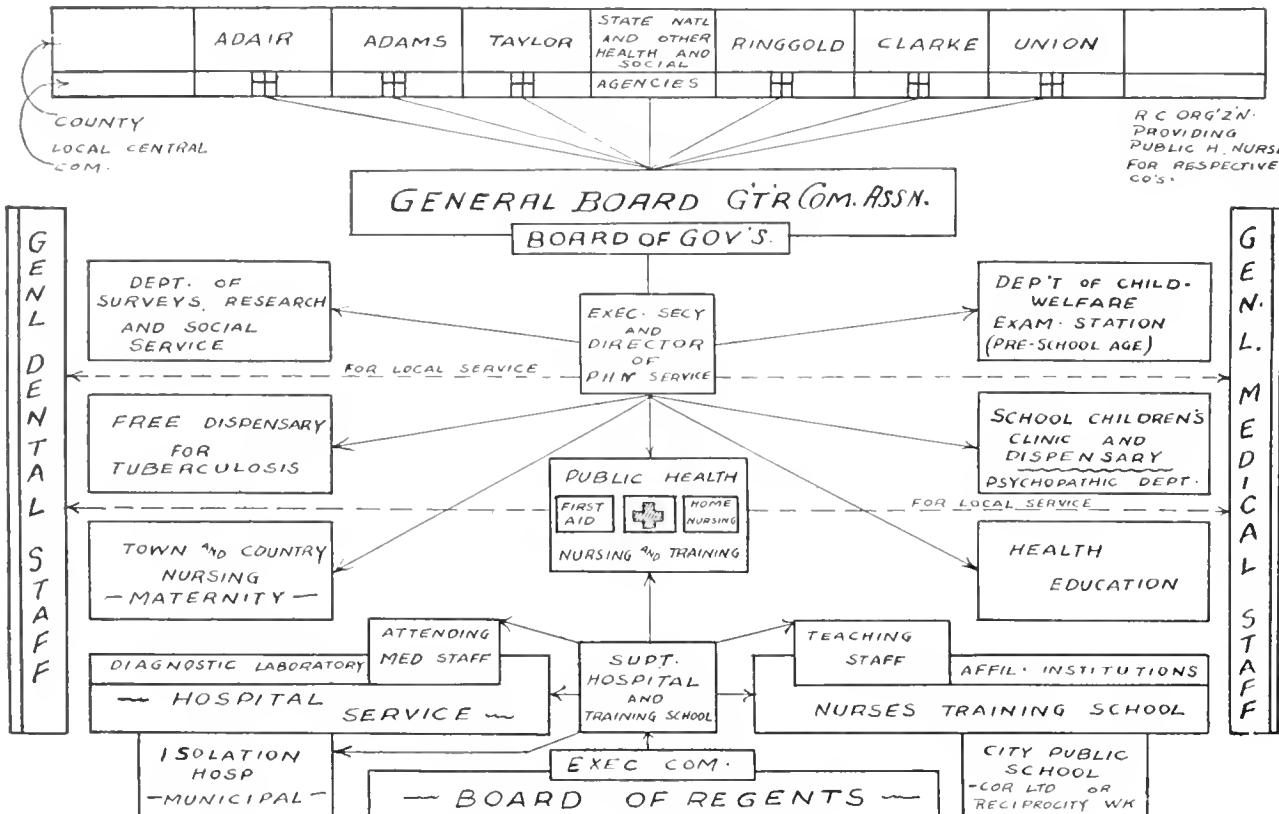

Fig. 3. Diagram showing organization of the government of the Greater Community Association.

neighborhood first, and thus demonstrate whether you have the vision of service. As a physician in your own neighborhood you must be identified with the great program of socialized medicine, and, only when preventive measures have failed and it is necessary to bring your patient to the hospital, will you find a welcome here."

The physicians of this community, among the most progressive in the country, with few exceptions have studied this plan and are heartily in accord with the general program. They are enthusiastic. Indeed, practically all of the county medical societies in the jurisdiction have taken memberships in the Greater Community Association, and the doctors themselves are discussing its reaches of influence with the people of the countryside and devising ways and means for success. Moreover, many physicians have themselves taken memberships in the association. Among the principles of the hospital management

Fig. 3.) Each participating group, however, has a committee of three, known as the social service committee. This committee represents the organization in what may be termed a general assembly. Necessarily the general assembly is a large body. This group selects the board of governors. Their jurisdiction is limited to the social side of the service, including the departments of child welfare, dispensaries, public health nursing, etc. The hospital and training school are in the custody and under the direction of the board of regents. This board is the supreme authority, and is elected by members of the association, individual and institutional membership voting. The hospital and training school is under the authority of a superintendent, who is responsible to the board of regents. (See lower line of diagram in Fig. 3.) The department of welfare, social service, etc., is under the authority of the executive secretary (a public health nurse), who

is responsible to the board of governors. (The board of governors is in effect the executive committee of the general assembly.)

The finances of the two departments of service, hospital (or scientific) department and the welfare (social) department, are entirely separate. All charity patients must come through the social service department, and this department is held accountable for the actual cost of hospital care. The hospital contributes the gratuitous service of its medical staff and the advantages of its organized diagnostic and nursing service. This puts it up to the welfare and "up-lift" agencies of each community to look after their own people or see to it that their county

thereafter is perpetually a member, so long as active interest in the association continues. Provision is made, however, to cut off any dead members. This money goes into an endowment fund, the purpose of which is to maintain a social service secretary and such office force as may be necessary to carry forward the work of the association.

Recently one of the board of governors brought in six memberships, and, in a number of towns in the various counties throughout the jurisdiction, every church has taken membership.

Each county is organized from within to co-ordinate its various forces for the promotion of community welfare and especially for the con-

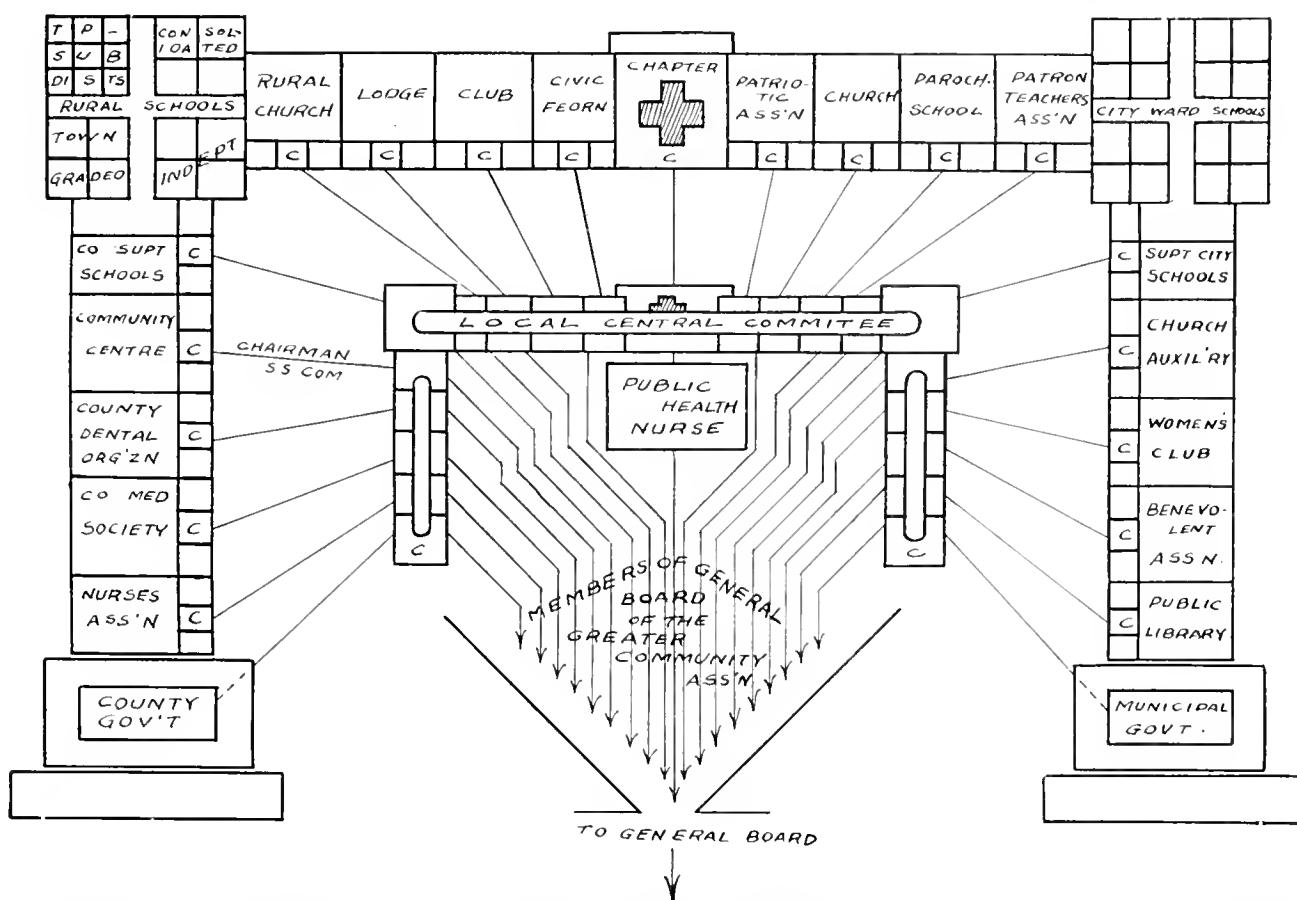

Fig. 4. Diagram showing local central committees of the Greater Community Association. These committees coordinate the local forces—social, fraternal, religious, educational, commercial, agricultural, industrial, professional, and political—for local service. Each trio of squares equals the social service committee of the organization; C stands for the chairman of the committee who represents his organization on the local committee and on the general board of the Greater Community Association.

assumes responsibility for the hospital expense. In either event, the medical staff contributes gratuitous service.

The assembly meets from time to time in discussion of the public welfare and health movements which have to do with general community betterment.

Membership in the association is \$25, payable but once. Each church, club, school, lodge, or other organization participating pays \$25 and

servation of human life values. (See Fig. 4.) The local central committee includes educational, medical, and local government administrative heads. The public health nursing activities are directed by the public health nurse (provided by the county Red Cross Chapter). The local central committees of the six counties meet quarterly in the assembly room on the fourth floor of the new Central Hospital building. The aggregated central committees constitute the general assembly

of the general board of the association. Each participating organization has its own committee of three members (the social service committee). The chairman of this committee represents his church, lodge, club, etc., on the local central committee, and is also a member of the general assembly where he is authorized to cast the vote for his organization in the election of the regents and the board of governors.

The American Red Cross is participating, and

manage it. The question here is, How shall the hospital be supported? The answer has been worked out in this way. No patient is received in this hospital free; someone must pay for room and board. An illustration will serve to make this point clear. The social service committee of a church at Bedford, forty miles distant from Creston, applies at the hospital for the admission of a woman who needs a surgical operation and is unable to pay. The secretary will then ask this

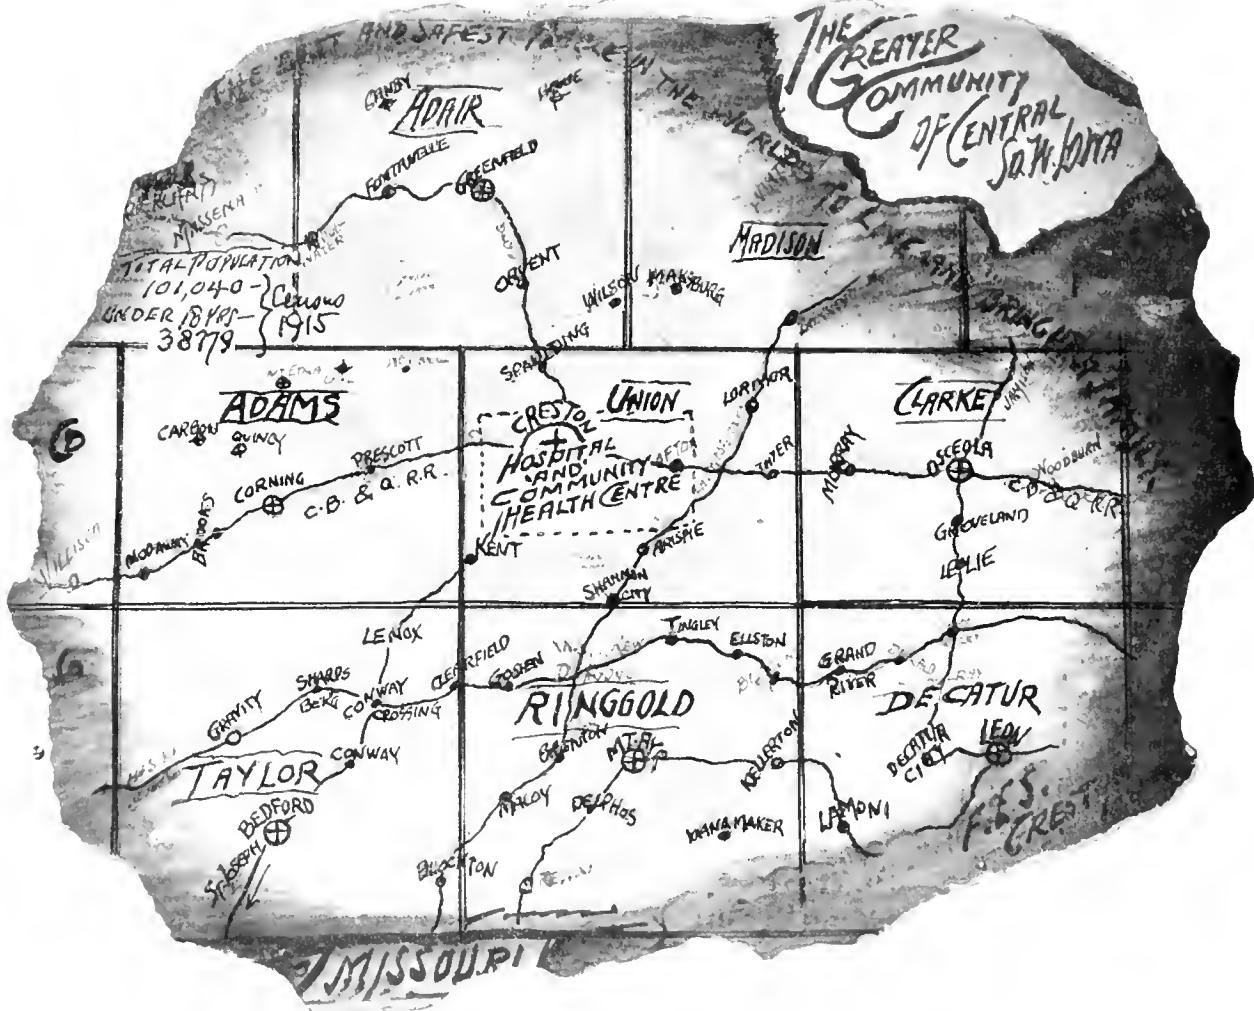

Fig. 5. Map of the six counties served by the Greater Community Association.

chapters and branches throughout the district have become a part of the association. A scheme has been worked out by county superintendents of some of the counties, at least, for Junior Red Cross membership in each township. There are nine schools in the average rural township. Nine schools combined will hold one twenty-five-dollar membership. Thus the juniors become a part of this great achievement.

The hospital does not receive any of its funds for operation expense from the Greater Community Association. A board of regents direct and

question: "Has your church sufficient interest in her to pay her room and board?" The answer being in the affirmative, the woman is brought by her physician; the operation is performed either by him or by a surgeon of the hospital staff. The room and board at the hospital are paid by the church, but neither the attending physician nor the member of the hospital staff can make any charge whatever for his services. The maintenance of the hospital is thus assured.

One of the charter principles of the confederation is that no physician, either in private prac-

tice or as a member of the hospital staff, can charge a fee for any service rendered by him to any patient whose room and board have been paid in whole or in part by any person or group or from public funds. That is, free professional service for charity cases is the contribution made by the physicians practicing in the hospital of the Greater Community Association. On the other hand, when a physician brings a patient to the hospital who is able to pay, the patient pays the regular hospital rate and whatever fee may have been agreed upon between him and his physician. Meanwhile the Greater Community Association has provided a hospital equipment and service as fine as can be had in any city of a hundred thousand.

Here, then, we approach what may be considered a solution to the problems of the rural hospital. We have a hospital which makes no attempt to pattern after the great city institutions, but is organized to meet the needs of a rural neighborhood. The Greater Community Association has been taught to regard the hospital as a repair shop, necessary only where preventive medicine has failed. The standards of this hospital are adapted, therefore, to the demands of a rural population, and the ethics governing the whole plan are expressed in the law: "Thou shalt love thy neighbor as thyself." This hospital has in itself three general functions: social service, which includes preventive medicine, child welfare, and clinics; nurses' training school; and the maintenance of an adequately equipped hospital, which challenges the finest scientific skill.

A great many plans have been suggested for a memorial to the American soldiers who have been killed in action or died of disease during the great war, but the Greater Community Association has established a memorial fund to be used for child welfare. This foundation is to perpetuate the name of a soldier who made the supreme sacrifice whose name otherwise would perish from the earth. The memorial is in the form of a tablet on the wall of the reception corridor of the hospital with the name of the man in whose memory the money is given inscribed upon it. Many liberal citizens are contributing Liberty bonds for this purpose. The idea is a beautiful one. The hope is that eventually an endowment will have been created large enough to support by its income a trained nurse whose entire time will be devoted to the care of the babies and little children of the hospital area.

Recently another feature has been added in the shape of a \$20,000 block of capital stock in the one daily newspaper published in the "greater community," which has been given into the care

and keeping of the Greater Community Association's board of regents; the income derived from this stock is to be contributed to the maintenance of the child welfare service, and with this is included assurance of adequate publicity for the work of the Greater Community Association. The story of how the hospital came to possess 40 per cent of the capital stock of this *Greater Community Newspaper* will, of itself, provide material for an interesting story and one that should carry encouragement to any who may be striving to promote efficient hospital service against the current of perverse political influence that not infrequently afflicts rural as well as urban communities.

I can not close this article without making the suggestion that this experiment is a tremendous challenge to the church. The fundamental principles of this organization are those laid down twenty centuries ago. It remained for a physician to discover the plan and to become the prophet of a new era. The church is beckoned forward. Public health and public morals are intimately related. Meanwhile democracy is justified.

CLINICAL CONGRESS OF SURGEONS PLANS HOSPITAL STANDARDIZATION

The meeting of the Fellows of the American College of Surgeons, gathered at the Waldorf-Astoria, New York, October 24, marks a most constructive step forward among hospitals. The day was given to hospital standardization. Two thousand, nine hundred and forty doctors were registered. In addition, a group of hospital superintendents and trustees was present.

Probably never before was so large a group of doctors assembled to consider hospital problems; nor did any group ever strike a higher or more unselfish note in considering hospital matters. Such a spirit in the medical profession means a new era among hospitals. It means coöperation. After years of work the College placed before the hospitals a "minimum standard" and then asked the coöperation of hospitals in meeting it. It asks coöperation only on the basis that the "minimum standard" is sound and right.

John G. Bowman, director of the College, stated the minimum standard as follows:

The Minimum Standard

1. That physicians and surgeons privileged to practice in the hospital be organized as a definite group or staff.
2. That membership upon the staff be restricted to physicians and surgeons who are (a) competent in their respective fields, and (b) worthy in character and in matters of professional ethics.
3. That the staff hold meetings at least once each month to review and analyze the successes and failures in the treatment of patients.
4. That accurate and complete case records be written for all patients and filed in an accessible manner in the hospital.
5. That clinical laboratory facilities be available for the study, diagnosis, and treatment of patients.

THE TRAINING SCHOOL OF PSYCHIATRIC SOCIAL WORK AT SMITH COLLEGE

BY EDITH R. SPAULDING, M.D., FORMERLY DIRECTOR PSYCHOPATHIC LABORATORY, WOMEN'S REFORMATORY, BEDFORD HILLS, N. Y.*

WHEN it was proposed last spring to train a group of social workers for the purpose of aiding in the re-education and treatment of the soldiers who were suffering from the war neuroses and psychoses, much anxiety was felt regarding what was considered very much of an experiment. What should such a group of women be taught? How could they be made of the greatest use? If they were to help carry out the instructions of the psychiatrist intelligently, would it not be necessary for them to know much of the detail of the mental life of the patients? Would not this knowledge necessitate their delving into fields which are usually unfamiliar to the lay worker, and even to the medical social worker? What would be the effect of dispensing such knowledge to young women, many of whom had only just finished college? Were they old enough to assimilate what has caused many an older person mental and emotional indigestion?

The Need Warrants the Experiment

Although we wondered and feared, at the same time we also desired. It seemed such an opportunity, such a chance to jump ahead in our ideals of mental hygiene, such an opportunity to broaden the field of the social worker. Besides, there was an urgent demand for persons thus trained. The physicians from Canada told of the great need of specially trained social workers to help in the reconstruction of their soldiers who were suffering from mental and nervous disease. A neuro-psychiatric unit had already been mobilized in our own country, which included some of our best mental nurses. But there were few social workers who had had the special training which would equip them to do the social work that might be necessary.

In giving such a special training, however, should we not be taking too great a risk in introducing to the theories and actualities of mental disease a group of young women who represented a variety of experience and training? In answering this, we had only to recall the pluck and endurance that had been shown by women of other countries in the midst of the most horrible situations, and to remember what some of our own

countrywomen had already accomplished, to be convinced that even though the war was two thousand miles away, a group of our women, if wisely chosen, would be equal to any task for which they were needed.

Furthermore, there was the question whether it was wise to take a group of women without medical training into the sacred precincts of the temple of psychiatric thought, which not infrequently had been withheld from the, shall we say, profane touch of the mental nurse. Here again the need seemed to warrant the risk taken. The psychiatrists themselves would hardly be able to devote as much time as would be necessary for the reconstruction of each case. Some one would have to help in carrying out the detail of the plans they would indicate. Should it not be a trained rather than an untrained person, and should not that training be the most fundamental possible?

Study Problems of Human Behavior

What part of the field of psychiatry should such a group be taught? We had no intention of including the whole field and attempting to make psychiatrists of lay workers. The greatest emphasis should, we thought, be laid on the study of the principles of mental hygiene. Much time should be devoted to the interpretation of mental symptoms, considered in general as they occurred under the headings of different mental diseases, and in particular as they appeared in the war neuroses and psychoses. From the first it was emphatically stated that our purpose was not to make diagnosticians of our students, but rather to cultivate in them a comprehending and sympathetic attitude toward the problems of mental disease. Therefore, a course was decided upon which should give to the students a knowledge of human behavior, both normal and abnormal, and should train them to be of practical use in the study and treatment of abnormal mental conditions.

Besides the course in psychiatry, there were courses in sociology and in psychology. Each of these from its own point of view aimed to show the struggles in the adjustment of elemental instincts which have been necessary as civilization has advanced from lower to higher levels. The course in sociology included lectures and confer-

*Read before the Mental Hygiene Section, National Conference of Social Work, Atlantic City, N. J., June 2, 1919.

ences on case work, and the practical problems of the adjustment of the individual to the community through the consistent utilization of its many resources.

In addition to the lectures in psychology, a short course was given in mental testing, again not with the purpose of making diagnosticians, but of increasing the student's understanding of the significance of mental tests when performed by others. Some of the class who had had previous experience were given opportunity to test patients at the State Hospital.

Continuity of Course Sustained

In order that the training given might be as intensive as possible and might represent the best work that has been done in the field of mental medicine, the cooperation of many of the leading psychiatrists of the country was asked. Vassar had already established such a precedent in the plan of a course for the training of nurses. This plan which we were glad to follow far exceeded our expectations in the amount of continuity it was possible to maintain and in the intense interest which it aroused among the students. In the course in psychiatry alone, there were twenty-three visiting lecturers. Contrary to what might be expected, the subjects followed each other in as consecutive a manner as if it had been given by one lecturer alone, and what repetition there was, was said on the authority of the president of the college to be good pedagogy!

The course in social psychiatry was introduced by a lecture on mental diseases in general. It was thought desirable to consider then the mental conditions that have a definite physical basis. This naturally took us into the field of neurosyphilis and the mental conditions that are caused by poisons and trauma.

Personality Studies Made

Early in the course the class studied history-taking in detail. Later on, there was required from each student a history based on this outline, which was to include a well worked out personality study. Each student was urged to take herself as a subject as it was supposed that in this way much data would be available. It was also felt that a knowledge of her own conflicts and adjustments would constitute one of the best preparations for her work with the conflicts of others. Personality was studied in the greatest detail, first as seen in the normal individual, and then as it develops in the various abnormal mental types in the disorders of delinquency, in the psychoneuroses, in mental disease of alcoholic or-

igin, in the manic depressive psychoses, and in *dementia praecox*.

The class was extremely fortunate in having two weekly clinics at the Northampton State Hospital. This added greatly to the interest of the course and made it possible for the students to see the various types of mental disease they were studying. Besides this, lectures illustrated by lantern slides and a moving picture film added to the graphic presentation of the subject. Once a week an evening lecture was given which the public was invited to attend.

Those who are familiar with the study of psychiatry know that there are different schools which deal with mental problems from quite opposite points of view. As it was probable that the different points of view would be presented in the various hospitals to which the students would be sent later on, it was thought advisable to present to them opposing opinions and theories even at the risk of causing some confusion. In order as far as possible, to eliminate unnecessary and unproductive controversy, each lecturer was asked to state his point of view frankly in the interpretation of mental symptoms, and to omit all expression of opinion which would tend to prejudice his hearers against other points of view.

Ready Response from Pupils

In looking back over the course, it seems impossible that the group should have been able to assimilate so much in so short a time. Each lecturer, however, spoke on the subject to which he had devoted much time and in which he was consequently greatly interested. His enthusiasm was contagious and the class responded with a corresponding amount of interest. They appreciated the opportunity of hearing men who had given years to the study of one subject, and faith in the judgment of these men enabled the students to utilize theories which, under other circumstances, it might have taken them years to accept. The four hours of lectures daily lengthened frequently into a much longer time because of the unflagging interest among the students and the lecturers. The additional four hours for daily reading, which supplemented the lecture hours, were conscientiously utilized.

The two months' course of didactic work at Smith College was followed by six months of practical work at various mental hospitals and clinics, where there was also opportunity for a continuation of the psychiatric instruction. At the present time, the forty students who completed the course are holding positions of responsibility in this country and in Canada.

As a result of last summer's experiment, a per-

manent school is to be established at Smith College for social work in the following four branches: psychiatric social work, medical social work, child welfare, and community service. Furthermore, three other schools of a similar type have been started in Philadelphia, Chicago and New York. If the interest in this type of training continues, it will be possible for every mental hospital and clinic in the country to be supplied with a psychiatric social worker.

Digressing a moment, let us consider life a series of adjustments, roughly classified as two-fold: First, the internal or the individual adjustment, and second, the external or the environmental adjustment. The rôle of the social worker is, we believe, to aid in the solution of the problems of maladjustments of both types. The task of the medical social worker, as we know it, consists first in aiding the physician to make the patient more fit physically (the patient's internal adjustment from a physical point of view), and second, in utilizing the social and industrial resources of the community in helping the patient make his external or environmental adjustment. The task of the psychiatric social worker consists first in aiding the psychiatrist in making the patient more fit mentally and in developing his personality to the extent of his individual capacity (the patient's internal adjustment from a mental point of view), and, second, in common with the medical social worker, in utilizing the resources of the community in helping him make his environmental adjustment.

Fundamental Requirements of Training

It is this difference which calls for the difference in training. The healing of a lung from tuberculosis or the treatment of a heart that is not functioning properly requires detailed treatment, it is true, but of a very definite nature, which demands usually the following out of a physical procedure. On the other hand, the treatment of mental symptoms and the adjustment of cases exhibiting anti-social conduct requires a knowledge of individual mental adaptability and development. The social worker who is to help carry out such treatment must be able to appreciate her patient's capacity for adaptability and assist the physician in helping the patient to make his individual as well as his environmental adjustment.

It is doubtless true that all of us, the mentally normal as well as the abnormal, are capable of greater powers of adjustment than we display; that with wise counsel, followed by the process of mental and physical re-education, we could all attain greater power and usefulness. The time

will come, we believe, when a knowledge of human behavior and of the principles of mental hygiene will be required in the training of every social worker. The war has brought about the realization of the need of such knowledge for the social worker in the field of psychiatry. Before long there should be a realization of the importance of such training in the field of social work in general.

The dissemination of knowledge regarding the principles of mental hygiene may be accomplished in two ways: (1) through the education of the mass by means of public lectures, literature, and educational procedure in general; (2) through the intimate contact between individuals in the clinic and in the home. It is in the second type of work that the psychiatric social worker has an opportunity to spread in a community knowledge of the principles of mental hygiene.

Recognize Social Maladjustments

In the past there have been on the one hand our mental hospitals where the psychiatrists come in contact with the well marked cases of mental disease; on the other hand, there has been the community where social maladjustments and incipient mental disease come only too seldom to the knowledge of the psychiatrist. The social worker is the natural go-between. She visits the hospitals and she visits the homes in the community. If she is equipped with knowledge that will enable her to recognize social maladjustments which should be corrected and abnormal mental symptoms when they first develop, she can guide the patients to appropriate channels, while readjustment is possible and the prognosis favorable. She will thus have vast opportunities for supplying the much needed link between social maladjustments and mental disease, or, in other words, between the community and the mental hospital.

To summarize what we believe to be the field of the psychiatric social worker, she will, through understanding of the true interpretation of mental symptoms, be able to spread in the community an attitude toward mental disease that will do much toward encouraging treatment in early stages. She will be able to carry out in detail and with intelligence the treatment which the psychiatrist indicates but which he does not have time to carry out, and she will be able to aid him in his study of each case by contributing a true picture of the patient's reactions in his different environments. Besides this, she will bring to the mental problems that confront the psychiatrist the help that a knowledge of the social and industrial resources of the community can contribute.

The psychiatric social worker is the outcome of a war emergency. What the field of war neuroses and psychoses might have evolved, and of what service these workers and others similarly trained might have been in work with our soldiers will perhaps never be known. Still a definite need for such workers, psychiatric aids they have been called, has already been recognized in the community. The opportunities of the future lie in applying their usefulness to the general field of mental hygiene. Since here the field is boundless, their opportunities will be unlimited. The degree of their success, however, will depend largely upon the opportunities given them by the psychiatrists and the community to prove their usefulness.

LAW FOR THE DOCTOR

BY LESLIE CHILDS, ATTORNEY AT LAW, KISSIMMER, FLA.*

Validity of agreement to pay attending physician percentage of damages recovered for personal injury.

In *Sherman vs. Burton*, 130 N. W. 667, the plaintiff, Dr. A. T. Sherman, was called to treat the defendant, Geo. E. Burton, for an injury to his knee, the result of a collision between cars on the Detroit United Railway. Subsequently the doctor and his patient entered into the following written contract:

"Detroit, Mich., March 14, 1906.

"I, George E. Burton of the city of Detroit, do hereby agree as follows with Dr. A. T. Sherman of the same place. I will pay to the said Dr. A. T. Sherman for professional services, one-third of any sum which I may receive from the Detroit United Railway, as damages, arising out of an injury to me on said D U. R., December 7, 1905. And I further agree to pay to said Doctor Sherman the sum of ninety dollars (\$90) in addition to the above mentioned one-third if the amount received by me is two thousand or more dollars, that is, if the settlement is made out of court."

GEORGE E. BURTON.

Later Burton, it appears, settled out of court with the railway company for \$1,800. He and Doctor Sherman had some difficulty in agreeing upon the settlement under their contract, which ended by the doctor bringing an action on the contract in which he claimed there was a certain amount still due him.

On the trial of the cause the testimony of Doctor Sherman and that of the defendant, Burton, his erstwhile patient, showed a remarkable degree of variance. The doctor insisted that it was Burton who conceived the idea of settling his doctor bill from a percentage of any amount in damages he might obtain from the railway company. That Burton proposed the contract, and that he (the doctor) objected to it, but finally upon the urging of Burton agreed to it.

When Burton took the witness stand, he was equally as positive that the contract was the child of the doctor's brain; testified that the doctor had remarked about what a good case he (Burton) had against the railway company, mentioning vague sums of money that could be obtained if the case was handled in such and such a way, and considerable more along the same line.

The court in reaching its conclusion made no apparent effort to reconcile the testimony of the parties; in fact,

gave little weight to the evidence of either, basing its opinion upon the principle of law involved and the intentions of the parties as disclosed by the written contract. The court said:

"At the time the agreement was made, the parties contemplated that unless a settlement was made a suit would be instituted against the Railway Company and the agreement expressly provided that, if the matter was settled out of court for \$2,000 or over, the plaintiff should receive \$90 in addition to one-third of the amount received. The amount which the defendant could obtain from the Railway Company must depend principally upon the nature, extent, and character of his injuries, to be determined by the testimony of experts like the plaintiff, and in no small degree by their opinions, incapable of conclusive refutation before a jury of non-experts. We think it necessarily follows from the circumstances of the case as disclosed by the plaintiff and the agreement that the parties contemplated that the plaintiff should be a witness in case of suit and should give a history of, and opinion upon the case in the event of a proposed settlement. The plaintiff's interest in the amount of damages furnished a powerful motive for exaggeration, suppression, misrepresentation,—a temptation to swell the damages so likely to color his testimony as to be imminent to the pure administration of justice, and therefore invalid." Holding that the physician could not recover under the contract, as it was invalid, for the reasons stated above.

The ruling in this case is in accord with the rule enunciated in a long line of similar cases that precede it. And, too, in every one of these cases the identical question arose, i. e., the question relative to the part the attending physician was expected to play as a witness in the prosecution of the contemplated damage suit, out of which his fee was in a measure dependent.

In none of these cases does it appear that the physician agreed to, or did, give anything but true testimony; there is an entire absence of fraud, collusion, or attempt to "fix" the testimony; yet contracts of this kind have been uniformly held invalid. These opinions have been quite generally based upon the probable effect the existence of a contract of this nature would tend to have upon the testimony of an attending physician at the trial of the cause.

It appears reasonable to suppose that a contract of this kind would be valid were it hedged about in such a manner as to show plainly that nowhere along the line was it contemplated that the attending physician should act as a witness, or participate in any manner in the negotiations between the injured party and the prospective damage payer.

But a case in accord with the above hypothesis has not, to the writer's knowledge, been brought before the courts, and, when the intimate relationship existing between physician and patient is considered, along with the usual method employed in the approximation of damages for a personal injury, it appears extremely improbable that there ever will be one.

EUGENICS AND IMMIGRATION

Usually the problem of immigration is considered only from its economic viewpoint, but inasmuch as the characteristics so acquired may improve a race or cause its deterioration, this process of absorption should be studied before it is complete. Thus reasons Dr. Alexander Graham Bell in the *National Geographic Society Bulletin*. Doctor Bell believes that Congress should provide an

*The eighth of a series of articles on "Law for the Doctor," written for MODERN MEDICINE, by Leslie Childs.

ethical survey of the people of the United States. "We should have definite and reliable information, concerning those foreign elements which are beneficial to our people and those which are harmful . . . The process of evolution should be carefully studied, and then controlled by suitable immigration laws tending to eliminate undesirable ethnical elements."

SANITATION OF SCHOOLS AND FACTORIES

The report of the sanitary conditions in the Framingham schools issued as *Monograph No. 6* is a somewhat delayed publication of detailed surveys made of conditions existing at the beginning of the Framingham Demonstration. One of the first steps of the Demonstration was

Fig. 1. As in most communities, the school buildings in the territory covered by the Framingham Demonstration vary from the old frame structures to modern brick buildings. Even in the best type of buildings, the design and construction do not always favor good illumination.

a general sanitary survey conducted by Mr. Franz Schneider, Jr., then of the Russell Sage Foundation. In the study of school conditions he was materially assisted by Mr. W. Turber Fales, an advanced student at the Massachusetts Institute of Technology.

The study deals strictly with general sanitary and hygienic conditions, indicates the approach to this field, and is perhaps suggestive of general conditions as regards school hygiene in American urban conditions.

The study does not purpose to cover the question of the adequacy of the plant as an educational institution; the interrelation is apparent, however, in the provision of sixty-eight rooms,—all types of buildings from old frame structures to modern brick buildings,—for a school population of about 3,000. Instances of children sitting so close to radiators as to be uncomfortable, or so near windows as to receive drafts are in part due to over-crowding and to inadequate equipment.

The tests for heating were made in May. Due allowance must be made for the fact that outside temperatures were not relatively low, nor were the conditions for humidity as unfavorable as in the winter when very cold air containing little moisture is heated to room temperature.

Many defects in temperature were recorded. More than half the rooms were above 70°; a fourth were above 72°; nearly three-fourths were above 68°. The extremes were 75.2° and 62.2°.

An important defect was noted as to the accuracy of the thermometers in use, one of which read 7.6° too high;

another 3.1° too low. More than half the thermometers read too low, a circumstance which tended to over-heating. It was emphasized that operation is the secret of good ventilation, even when modern mechanical plants are provided. It is an evident folly to spend thousands of dollars on expensive ventilating equipment and then turn it over to the sole control of a man who does not thoroughly understand what the apparatus is designed to do. It is recommended that supervision of ventilation be placed in the hands of the full-time school inspector, and that he receive the teachers' reports of temperature, make tests of ventilation from time to time, and see that proper conditions are maintained.

Fifty-four rooms were studied as regards window and floor area space, the finish of the walls, and the nature and condition of the shades. A watch was kept for glare.

Taking all the rooms together, nearly 50 per cent of them were poor or bad with reference to the proportion of glass to floor area. In some of the rooms the placing of the windows constituted conditions obviously serious. It was not found possible to correct these conditions by artificial lighting, and usually the shades did not afford the means of control.

The recommendations as to lighting emphasize the un-

Fig. 2. Examples of fixtures which indicate a poor installation for cleanliness,—spring faucet, an impractical bowl, no soap, and a cup fountain.

Fig. 3. This is good equipment for cleanliness, non-spring faucet, bowl, individual towels, soap from holder, and a convex fountain.

satisfactory design of the older schools. The conditions in each room should be scientifically studied and properly regulated,—another important function for the full-time inspector of schools.

Other recommendations had to do with seating, with washing facilities, and with adequate provision of drinking fountains of hygienic type. Special emphasis is laid upon a consistent policy of janitorial instruction regarding the many details of the hygienic management of the school plant.

Framingham is a typical American industrial community. In the industrial survey of typical plants which

Fig. 4. The flashlight photograph at the left shows a dark interior. The side light from the windows comes from a covered porch. The defects in the lighting and arrangement of windows are more apparent when contrasted with the photograph at the right where the seating is excellent.

was made some time ago three principal phases were developed:

(1) A special study of ventilation in certain typical plants where the questions of dust, fumes, chemicals, and general ventilation were touched upon. This was carried out through the cooperation of the New York State Commission on Ventilation.

(2) A special study of safety in a number of the Framingham plants, conducted by the New York Museum of Safety.

(3) A general sanitary study of the great majority of the Framingham industries, over-lapping in a general way the particular interests touched upon more intimately by the special ventilation and safety studies, carried out through the cooperation of the Massachusetts State Board of Labor and Industry.

The technic of the procedure in the investigation of dust and ventilation is given in detail. Tabulation is made of the results of the dust samples in six establishments. With two exceptions they are characterized as "dusty" or "very dusty." Comparison of dustiness on the basis of counts alone is, of course, meaningless. None of the samples taken was considered abrasively dangerous.

The study of mechanical hazards led to recommendations regarding power control, standard conduits for wiring, locking off apparatus for repairmen working on electric lines. Goggles are mentioned for the prevention of life accidents. The fire hazard was regarded as the greatest danger in Framingham industries. The general recommendations state that "the chief problems are those of equipment and method as to general sanitation, depending for their solution in large part upon the personal factor, and therefore on an effective program of education as to personal hygiene."

"Evidently the meeting of all the needs indicated involves not only improved hygienic conditions, but a more adequate personnel for medical, nursing, and clinic service."

BACTERIOLOGISTS MEET IN BOSTON

The Society of American Bacteriologists will hold its annual meeting in Boston, Mass., December 29 to 31, 1919. General and technical bacteriology will occupy the Conference on December 29 under the direction of S. H. Ayers, of the Bureau of Animal Industry, Washington, D. C., and agricultural bacteriology will be directed by

H. J. Conn, Agricultural Experiment Station, Geneva, N. Y.; John W. M. Bunker, of Digestive Ferments Company, Detroit, Mich., presides at the Public Health Section, which program is arranged for December 30. Comparative pathology will be presented by C. P. Fitch. The last day of the session is devoted to human pathology, under L. W. Famulener, St. Luke's Hospital, New York, and to immunology under C. G. Bull, School of Hygiene, Baltimore, Md.

As we go to press the programs on the several subjects are not completed, but as each section is to be a sort of open forum for the presentation of the outstanding work in that field, the meeting promises to be one of the most important meetings of the Society up to this time.

INTERNATIONAL CONFERENCE OF WOMEN PHYSICIANS*

The closing sessions of the International Conference of Women Physicians were devoted to specific phases of social morality. That these problems are being attacked in a scientific, unprejudiced manner is evidenced by the liberal attitude taken by some of the representative physicians.

"Most men and women desire abolition of prostitution," said Katherine B. Davis, "but how shall we go about it?" Segregation has failed as have efforts to curtail vice by legislation, injunction, and abatement.

If a double standard is to be retained, the alternative is a sanction of polygamy and concubinage; if a single standard is to be accepted, it will have to be a modifica-

* Prepared from notes supplied by Dr. Dora Greene Wilson, Kansas City, Mo.

tion of the present standard for men, which would involve educating the people to the toleration of sex indulgence. Such a program would necessitate birth control. Marriage and divorce laws would need to be revised. Scientific research would need to be invoked to work out such a program, but it is a possible solution that would do away with prostitution, and would provide one standard for men and women. Prostitution cannot be made safe. The Government has accepted the single standard "fit to fight," and all agencies should join forces to legislate and enforce fair and decent standards.

The white slave trade was the question treated by Alicia

ers, or wives and widows, in the support of their children. Out of 3,330 children cared for by one government bureau, 2,603 were illegitimate.

The Psychological Section of the Conference found that as friends they had very much in common but as psychologists they could not come together in a report of findings. A sort of general resolution was offered:

"Inasmuch as mental health is fully as important as physical health, we as medical women place ourselves on record in support of a movement to make all schools and colleges responsive to the emotional and instinctive as well as the intellectual needs of children and young people,

Group of inter-allied physicians who attended the recent Y. W. C. A. National Board conference during the six weeks from September 15 to October 25, under supervision of the War Council of the Y. W. C. A. Never before has there been such a large gathering of noted women doctors assembled at one time. Sitting, left to right: Dr. Marie Feyler of Lausanne, Switzerland; Dr. Constance Long, London, Eng.; Dr. Mary Gordon of England; Dr. Tomo Inouye, Japan; Dr. Radmilla Lazarewitsch, from the legation of the Serbs, Croats, and Slovenes in Washington, D. C.; Dr. Yvonne Pouzin, Nantes, France. In the second row, standing, l. to r.: Dr. Christine Murrell, London; Dr. Alice Armand Ugen of Montevideo, Uruguay; Dr. Frances S. Johnston of Edinburgh, Scotland; Dr. Ada Potter, Utrecht, Holland; Dr. Natalie Wintsch, Lausanne, Switzerland and Dr. L. Thuillier, Landry, Paris, and Dr. Margerite Gibeulet, Paris, France. (Photo by Western Newspaper Union.)

Moreau, M.D., of Argentina. There is little change through the ages in this traffic, said Doctor Moreau. It is an ally of prostitution everywhere. It is very flagrant in Argentina. Many states in South America have signed to abolish the traffic but it is not enforced. The causes of white slave trade are economic, social, and psychic. Socially, women should have the same rights as men. Illegitimate maternity should be protected by society.

Psychic conditions offer greater difficulties. The education of the masses is involved. Prejudice is to be overcome. Sex education is to be improved, and the period of adolescence safeguarded. Nothing is impossible. The cause is gaining advocates and solutions will be found.

Illegitimacy was presented by Dr. Anna Moutet, Lyon, France. Her plea was for the protection of motherhood out of wedlock. The needs of a nation whose population is decreasing tends to lessen the prejudice which makes the unmarried mother an object of general censure. If irregular birth is no longer a disgrace to the child, neither must it be a dishonor to the mother. Stringent laws should attach responsibility for the child to the father.

"In 1917 France assisted 70,562 abandoned girls, moth-

to the end that education may become an instrument for teaching the best social adjustments possible."

On sex education they presented the following:

1. WHEREAS, Sex education and understanding are necessary for all human beings, in order that they may understand new complexities of their own lives, and their duties to the social organism, and

WHEREAS, The understanding of sex is one of the most effective ways of meeting the problems of prostitution and numeral diseases we are of the opinion that

A—Definite sex education should be given in all normal schools, training schools, medical colleges, and universities in order that future teachers and parents may be enabled to handle the subject wisely in teaching the children, as it comes up in the home and in teaching the subject in schools.

B—While waiting for a trained leadership to be obtained, that we continue sex education with the means we have at hand in all social classes and groups.

Resolved, That physicians shall call the attention of parents to the importance of sex education, and give them the instruction necessary to that end.

THE MONTH IN MEDICINE

Survey of Current Medical Literature with Editorial Comment

WALTER W. HAMBURGER, M. D., Editor

ANTE-NATAL SYPHILIS

ROUTH¹ offers a novel and decidedly interesting explanation of a possible relation of antenatal syphilis to the proteolytic action of the chorionic ferments. In his opinion, in contrast to most writers, paternal infection of the ovum is not only possible but probably not infrequent. He quotes many authorities in support of this contention and emphasizes the importance of certain clinical observations not in accord with the decidedly more prevalent view that syphilis is transmitted to the fetus solely through the mother.

His theory in the main is based upon the assumption that the investigations of McDonagh, O'Farrel, Balfour, Noguchi, and others have definitely established that either "spores" or "granules" play a rôle in the life cycle of the *Spirochaeta pallida*. It is held that under certain conditions typical spirochetes have been observed to develop from such spores, or spirochetes, to break up into granules, from which eventually normal spirochetes re-develop. Routh summarizes: "Taken as a whole, these observations seem to show that when attacked by salvarsan, and probably other drugs, by antibodies or toxins, the spirals of the spirochete may break into granules which may for a time remain latent, and then, unless themselves destroyed by the same agents, may develop into mature spirochetes under other circumstances at some later date."

Chorionic (syncytial) ferments are present at the point of interdigitation of the fetal and maternal portions of the placenta. These ferments, or their derivates, Routh considers capable of exercising destructive properties upon the *Spirochaeta pallida*, which may be present either in the maternal intervillous or fetal intervillous tissues, both of which are in intimate relation with the syncytial cells of the villi whence the ferments arise. This destructive action of the chorionic ferments is able to break the spirochete

into granules. During pregnancy, action of these ferments may continue on these granules, render them latent and biologically inactive, and perhaps occasionally may actually destroy them. After pregnancy, with the disappearance of the chorionic ferments, the granules re-develop into mature spirochetes. On the basis of this theory Routh attempts to explain four of the main problems evidently incompatible with the prevailing view that direct paternal transmission of syphilis to the fetus is impossible.

(1) Why can a pregnant woman, who later gives birth to a syphilitic child, have a negative Wassermann reaction during her pregnancy, and for some time afterwards? This negative reaction can only occur in cases in which the ovum has been infected by the paternal seminal fluid, either at fertilization, or after the fertilized ovum has reached the uterine mucosa, and when the mother hitherto has escaped direct infection. The chorionic ferments either break the seminal spirochetes into granules or, if the ovum is already infected, it can contain only granules, since the mature spirochete is longer than the head of the spermatozoid. These granules would be kept inactive by the chorionic ferments and during pregnancy could not develop into spirochetes. The mother could be infected only by latent granules. After pregnancy, about fifteen days, according to Abderhalden's investigations concerning the disappearance of the chorionic ferments,—granules still present would develop into spirochetes, when the reaction would gradually become positive.

(2) Why are some syphilitic children at birth and for some time afterwards negative? It seems probable that this will occur in the cases in which the ovum is primarily infected by paternal syphilitic semen or soon after fertilization. Granules formed under the influence of the chorionic ferments are prevented by them from further development till after the child's birth. It is even possible that during pregnancy the protective chorionic ferments might actually prevent maternal spirochetes from invading the fetal tis-

¹ Routh, Amand J.: Am. Jour. Syphilis, 1919, II, 484.

sues, which would lead to a positive reaction of the mother, and to a permanent negative of the child.

(3) Why are spirochetes so rarely found in abortions, even though alternating between still-births in whose tissue they are swarming? Some observers have suggested that the early abortions, so commonly seen in syphilitic women, are not actually due to the syphilis but to abnormal uterine conditions. Routh thinks that if chorionic ferments had been able to granulose spirochetes from father or mother before they could infect the ovum, naturally no spirochetes could be found in the early abortion ovum. Later in pregnancy, maternal spirochetes might succeed in entering the ovum in spite of the protective ferments. It is quite likely that granules, resulting from the spirillolytic action of the chorion, could be found in the embryonic tissues of early abortions, if looked for carefully.

(4) He finally discusses Colles' law from the point of view of his new theory. Colles' original statement was that a woman who gives birth to a syphilitic child does not get infected by that child after its birth. The words of this "law" still hold good, but the general view now held is, that she does not get infected because she already is infected, "every syphilitic child having a syphilitic mother." Whenever this is true, the mother actually has a positive reaction; but occasionally she is found negative during pregnancy, and for a shorter or longer time after delivery. Routh suggests that she has been infected by granules only; when the store of chorionic ferments is exhausted the spirochetic granules develop into the mature organisms.

Comment.—In his closing remarks the author himself points to a few of the objections that might be raised against this undeniably appealing explanation of some of the intricate problems of the transmission of syphilis to the fetus in the uterus. Physiologic and pathologic chemistry of the placental ferments is but little understood; the very presence of such ferments is difficult to demonstrate. So far, not even the action of such ferments on the living spirochetes has been studied. Experiments and tests of all sorts will be required to confirm or disprove this theory. But Routh fails to mention the one most important argument that obviously must be made. Is the spore or granule stage of the *Spirochaeta pallida* really an established fact?

A spirochete is too large to enter the head of a spermatozoid. The entire problem of the direct paternal infection of the ovum, therefore, hinges solely on the question of this assumed granule stage. Routh apparently considers this question

as solved beyond any reasonable doubt. There are many who will thoroughly disagree with him on this point.

H. E.

CURRENT ADVANCES IN PEDIATRICS

IT IS surprising that in spite of the increased demands made on pediatricians during the war both at home and abroad, a great deal of work has been done in pediatrics that is of permanent value. We shall dwell here on only a few of the contributions made to pediatric literature during the last year.

Owing to the scarcity of milk in the European countries, a renewed interest has been evinced in natural or breast feeding. Dozens of articles have been written on the value of maternal nursing, and on the importance of infant welfare work. Of real interest is the attempt made by Chessier,¹ to stimulate the breasts, in cases in which they fail to secrete sufficient milk, by means of faradization. She uses two hollow, cone-shaped, flexible zinc electrodes. The circular bases fit round the breasts and they can be adapted evenly to the surface of the glands. The electrodes are fixed in place with an elastic bandage. An ordinary faradic coil is used, and the connecting cables are attached from the secondary terminals to soldered terminals on the electrodes, which may be used bare or underlaid with several layers of moist lint. The current is passed through the two breasts for twenty minutes twice, or even three times a week. The patient feels a gentle tingling; there is no discomfort or pain, and the only inconvenience consists in having to strip to the waist so that the electrodes may be properly applied.

The results of the treatment surpassed the author's expectations. In the ten cases treated the children improved in health and showed an average gain in weight of $3\frac{1}{2}$ to 5 ounces a week. In six cases the average gain in weight prior to beginning electric treatment was $1\frac{1}{2}$ to 2 ounces a week; in four cases the treatment was instituted at the first or second attendance of the child at the clinic, as the test meal showed that the infants were having less than half the required amount of milk from the breasts and the cases seemed urgent. This work is interesting and should be tried by pediatricians with the hope of lessening the number of infants who must be robbed of mother's milk because of scarcity of milk in the breasts.

In the line of artificial feeding, no startling revelations have been made, but it is gratifying to see a calming down in regard to fancies in

¹ Chessier: *Lancet*, Lond., Sept. 14, 1918.

feeding. Talbot² points out that we must not go to extremes, that both the caloric requirements and the percentage of the milk elements should be taken into consideration. He also emphasizes the importance of combining the clinical symptoms with a study of the stool. The article by Talbot takes on greater importance by the fact that until very recently people drew an imaginary line between the so-called Boston method, or percentage feeding, and the Chicago method, or caloric feeding.

Dry milk has become quite popular in this country. Dennett³ believes that dry milk is better tolerated by those infants who have already received a food injury than raw or boiled milk mixtures. He bases his observation on a study of more than fifty cases in private practice which have been followed over a prolonged period with the utmost care. He also found that dry milk will often control vomiting, overcome intestinal indigestion, and increase the child's weight.

Hess and Unger⁴ studied dry milk from the standpoint of scurvy and found that, when given to a guinea-pig to the equivalent of 80 cc. of fresh milk, it was able to cure scurvy. They also tested dry milk in two cases of human scurvy. The babies showed the typical signs of scurvy, peridental hemorrhage, tenderness of the femora, and the milder symptoms of scurvy. When the diet of the one child was changed from malt soup to four ounces of dried milk diluted with a quart of water, there occurred distinct improvement in all the scorbutic signs and in the general condition. In the other case the malt soup was replaced by the same quantity of dried milk solution (one quart) to which, however, malt, flour, and potassium chlorate were added according to the previous formula. In this instance, likewise, a decided improvement in the scorbutic signs occurred; the hemorrhages of the gums disappeared, the child soon began to stand, and her temperament became happier.

In the line of nutritional disturbances, Hill's work is interesting. Hill⁵ gives a critical review of sugar in its relation to infant feeding. He admits that sugar is the disturbing element in alimentary intoxication, but he is not convinced that the salts in the whey of cow's milk also contribute to the intoxication. So, while he uses Eiweiss (protein) milk in cases of sugar fermentations, he is not certain that the exclusion of salts in the Eiweiss is responsible for the therapeutic effect. He goes still further, claiming that Eiweiss contains as much salt (NaCl) as undi-

luted cow's milk, and much more than woman's milk, and, therefore, he does not see how the salt could be responsible for the intoxication.

A marked turn in the line of treatment of gastrointestinal diseases has been noticed in connection with pyloric stenosis. Of late the treatment of pyloric stenosis had been accepted as surgical. It is, therefore, a relief to find some one who attempts to treat pyloric stenosis medically.

Sauer⁶ obtained good results by the feeding of thick cereal. He prepared the cereal in the following manner:

Skimmed milk	9 oz.
Water	12 oz.
Farina	6 tablespoons
Dextri-maltose	3 tablespoons

Boiled for 1 hour in a covered double boiler.

During the past four years the author used thick cereal feeding in twelve cases of pyloric stenosis. In eleven of the twelve cases the vomiting soon stopped, although in most of the cases the peristaltic waves and the tumor, where palpable, persisted for weeks or months after the vomiting ceased. As to the character of the action of the thick cereal, the author says that it seems likely that the thick, immobile cereal can not be ejected from the stomach by the sudden explosive contraction that produces vomiting of milk feedings. The thick cereal remaining in the stomach can be moved along by the slow peristaltic contraction of the gastric wall.

The observations of Sauer are corroborated by Porter.⁷ In the ten cases under his care so treated the results have been as striking and as satisfactory as in the cases reported by Sauer. None of the ten has been brought to operation; in all the vomiting ceased so promptly that it seemed almost a miracle, and, with cessation of the vomiting, came a rapid and gratifying restoration of nutritional balance. There were a striking increase in tissue turgor and marked improvement in the child's well being.

Still⁸ gives a lengthy discussion of celiac disease, or chronic diarrhea. The child is pale and emaciated; the large abdomen contrasts with the wasted limbs, and the general appearance is that of tuberculous peritonitis, for which celiac disease is apt to be mistaken. The most striking feature is the surprising inconsistency of the child's size with its age. What appears to be an infant little more than twelve months old startles one by unexpectedly talking, and so reveals the fact that it is at least a year or two, or perhaps three or four years, older than its appearance would suggest.

The child's stools are generally pale or the color of oatmeal. At intervals of a few weeks the stools

⁸ Still: Lancet, Lond., August 10, 1918.

become more loose and frequent, perhaps three or four a day instead of one or two. These recurrent bouts of increased looseness are very characteristic of the disease.

The disease drags on for months and years. The child passes an invalid existence with intervals of improvement followed by relapses until, as a result of rigorous dieting, the stools gradually become more normal, and the child eventually struggles back to health, able to take food more or less like other people, but handicapped in growth by the lost time during which the development has been arrested.

Hirschsprung's disease is discussed by Carr.⁹ The diagnosis of megacolon is made readily when the record of a child is complete, but it may be puzzling when a history is unobtainable. Medical treatment of these patients is largely symptomatic and it is probable that children who have a minor defect in the development of the large intestine go through life without serious evidence of colonic enlargement and obstruction. When such patients are under medical care, laxatives, special food, and an occasional enema will relieve them. The more serious cases of Hirschsprung's disease are to be treated by enemata to empty the rectal pouch and high irrigations when there is impaction in the sigmoid or colon. Mechanical evacuation with the aid of a sound or the finger is to be used if the enemata are not effectual.

Influenza naturally occupied an important place in pediatric literature during the past year. Montgomery and Dunham¹⁰ found that the tendency in uncomplicated influenza in infants and children was toward a leukopenia rather than a leukocytosis; that there was a tendency to a slight leukocytosis in complicating pneumonia, and that in all pneumonia cases resulting fatally the leukocyte counts were under 10,000.

Levinson¹¹ found that the course of the disease in children, like that in adults, was mild or severe; that is, there were two groups of cases, those which did not develop pneumonia, and those which did. The physical findings in the former were practically nil except for a pharyngitis which was aggravated by irritation from the cough. The rash noted in a few cases could be traced to belladonna or serum; it usually occurred late, or after the attack had subsided. In twelve cases he noticed, opposite the second molar, a group of shining round vesicles closely aggregated, the mucous membrane all around being markedly congested. This condition lasted from three to four days.

Allowing for the normal differences in the blood

of children and of adults, the changes in the blood in influenza seemed to be about the same, namely leukopenia and lymphocytosis, the leukocyte count running from 6,000 to 8,400 which, of course, is a leukopenia for children. A leukocytosis takes place on recovery. In most uncomplicated cases the differential count showed a distinct lymphocytosis, although in a few it was normal. The red blood cells were usually below five million. The urine in children as a rule was normal, albumin generally absent.

The question of vaccine therapy still holds the arena. The use of pertussis vaccine is as unsettled now as it ever was. Huenekens¹² found that two to four weeks old pertussis vaccine conferred immunity in from 25 to 75 per cent of cases. Freshly prepared vaccine, employed in the same dosage, shows evidence of antibody formation in 94 per cent of cases. When used in still larger doses,—one, one and one-half, and two billion,—100 per cent positive reactions were obtained. The antibodies were demonstrable within one week after the last injection.

Barenberg¹³ reaches the conclusion that pertussis vaccine, given even in large dosage, not only has no curative effect, but does not tend to lessen the severity of the disease. As regards the prophylactic value of pertussis vaccine, the case is different. In two epidemics the percentage of vaccinated children who developed the disease was considerably less than of those who were not vaccinated. The author emphasizes the fact that in his study it was possible, for the first time, to vaccinate children some weeks before they came in contact with cases of pertussis, and that, therefore, there was no chance of their having been in the incubation stage at the time prophylactic therapy was instituted.

Hess and Unger¹⁴ studied the question of protective therapy for varicella. Thirty-eight children were injected by them intravenously with the contents of chicken-pox vesicles. Of this number only one developed chicken-pox subsequently; the rest did not, although they were all exposed to the disease. The authors believe that the acquisition of immunity indicates that the specific virus is contained in the vesicles.

Findlay persists in his "close air" theory of the causation of rickets. Paton, Findlay, and Watson¹⁵ found that pups kept in the country and freely exercised in the open air remained free of rickets although they had actually a smaller amount of milk fat than those kept in the laboratory, while the animals kept in the laboratory all developed rickets.

Juvenile diabetes, which was considered fatal, holds out a ray of hope by the three cases reported by Horowitz.¹⁶ The author concludes that diabetes in children is not necessarily fatal and that, if they can be tided over for a certain length of time, they will outgrow the tendency.

Brennemann¹⁷ reviews the literature on rheumatic nodules and expresses the view that pos-

sibly nodules are not found by people because they are easily overlooked. The author attaches special importance to the nodules found on the knuckles. The hand is the only exposed part in this connection. By a glance at the knuckles in such a case, the author has been able to say: "This child has rheumatism; it is probably active; it is severe; he has an endocarditis."

COLLECTIVE ABSTRACT PRESENT DAY PROBLEMS IN OBSTETRICS

BY JOHN T. WILLIAMS, M.D., F.A.C.S., BOSTON, MASS.

IT may be stated as an axiom that the ideal of the practice of obstetrics should be the attainment in every case of the four following conditions: (1) a living mother; (2) a living child; (3) a child normal in every respect and free from injury or disease; and, finally (4) a mother left in good health and able to take her part in the world as well as before her confinement.

Vital statistics show that we are still far from accomplishing the first two of these objects. The maternal and fetal mortality are appalling. The pediatric and gynecologic clinics reveal numerous failures to attain the latter two objects. The purpose of this review is to point out as far as possible where these failures lie, to show what efforts are being made to overcome them, and to enumerate the unsolved problems of present day obstetrics.

MATERNAL MORTALITY IN OBSTETRICS

The statistics of the Metropolitan Life Insurance Co. for the year 1916 show that among more than two and three-fourths millions of women of the child bearing ages, 15 to 44, among its policy holders there were 1,769 deaths from diseases and conditions incident to childbirth. Puerperal infection was responsible for 41 per cent of these deaths; conditions characterized by albuminuria, including both toxemias and chronic nephritis, caused 29 per cent; accidents of labor accounted for 10 per cent, hemorrhage for 8 per cent, and abortions and miscarriages, also, for 8 per cent of the deaths; miscellaneous causes made up the rest.

Harrar¹ collected the statistics for 100,000 cases of labor delivered by the New York Lying-

In Hospital, including both indoor and outdoor departments. In the outdoor department, among 69,081 cases there were 218 deaths, or 0.31 per cent mortality. In the indoor among 23,130 confinements there were 109 deaths, or 0.47 per cent mortality among the regular patients of the clinic; but in the emergency cases sent in by physicians from outside the hospital the maternal mortality rose to 5 per cent. Here again puerperal infection heads the list, being the cause of death twenty-three times in the indoor clinic, and fifty-nine times in the outdoor department. Eclampsia and albuminuria again ranked second with 10 deaths in the indoor and 26 in the outdoor patients. Peritonitis following Cesarean section caused 16 deaths, which should be added to those above given for sepsis. Rupture of the uterus and *placenta praevia* were next in order of frequency. The other causes of death given were nephritis, cardiac decompensation, pneumonia, shock and hemorrhage following Cesarean section, shock and exhaustion, postpartum hemorrhage, pulmonary tuberculosis, toxemia without convulsions, accidental, abdominal pregnancy, rupture of vaginal vault, pulmonary embolism and thrombosis, suicide in acute mania, carcinomatosis, brain tumor, sarcoma of liver, ether and chloroform narcosis, and unknown.

Infection the Chief Cause of Death

DeLee² states that in the registration area of the United States 10,518 women died from childbirth during the year 1914; at least 4,664 of these died from puerperal infection. Lobenstine³ quotes the death rate from childbirth in the United States as 14.9 per 100,000 of total population.

¹⁶ Horowitz: New York Med. Jour., August 30, 1919.

¹⁷ Brennemann: Am. Jour. of Dis. of Children, Sept. 1919.

¹ Harrar, Am. Jour. Obst., 1918, lxxvii, 38.

² DeLee, Am. Jour. Obst., 1917, lxxvi, 15.

³ Lobenstine, Am. Jour. Obst., 1917, lxxvi, 381.

These figures demonstrate the existence of a considerable maternal mortality in obstetrics. In spite of modern aseptic technic the chief cause of death in childbirth is still puerperal infection. Though the work of Pasteur, of Holmes, and of Semmelweis has produced an enormous reduction in the incidence of puerperal infection and has effected a wonderful saving of human life, the wastage of womanhood from this cause has not been eliminated. It may be said fairly that, in the author's estimation, no small part of the incidence of infection is due to the failure to carry out well known and commonly understood aseptic methods, such as shaving the vulva, adequate scrubbing before every examination, avoidance of unnecessary examinations, etc. The writer recently reviewed an otherwise admirable textbook of obstetrics in which the author stated his conviction that shaving the vulva is unnecessary. That same author, although he advised just as careful preparation of the obstetrician's hands for a delivery as for an abdominal operation, was satisfied to operate through a field prepared in a manner that he would not have tolerated for an abdominal section.

However, even at the hands of men whose aseptic technique is as careful as it is possible to make it sepsis has not been altogether eliminated. The conduct of labor without vaginal examinations as advocated by Green⁴ or the substitution of the rectal for the vaginal examinations advised by DeLee⁵ and others has definite place in the prophylaxis of puerperal infection. It is certain, however, that infecting organisms may gain access to the vagina in other ways than on the examining finger. DeLee⁶ gives an excellent discussion of these methods of transmission. He found that the least number of postpartum fevers occurred in patients cared for at home; the next smallest number in those cared for in a hospital limited to clean maternity cases, and much the largest number in those delivered in general hospitals. The aseptic technic was the same in all cases.

Epidemics of Infection

The occurrence of epidemics of infection in lying-in hospitals is a well recognized fact. Therefore, it is not sufficient simply to maintain excellent aseptic technic in the delivery room. The patient must be guarded from exposure to possible sources of infection before and after delivery as well. Among the less common sources of infection which must be recognized and guarded against are the entrance of dirty water

in the vagina during the bath, coitus during the last weeks of pregnancy, transmission of pyogenic organisms from a focus elsewhere on the patient's own body, contamination from infected bed pans, bed clothing, or mattress.

As regards the treatment of puerperal infection recent literature is barren. In the past nearly every conceivable form of surgical intervention has been tried: curettage, instrumental and digital, incision of the posterior culdesac followed by packing with iodoform gauze, ligation of the internal iliac and ovarian veins, and even hysterectomy. Practically all these procedures have been abandoned, and the surgery of puerperal sepsis is to-day limited to the evacuation of localized collections of pus.

Following the failure of purely surgical methods there came an era devoted to attempts to reach the infection by systemic measures. The intravenous use of silver salts, bichlorid of mercury formalin, magnesium sulphate and latterly, arsenobenzol⁷ have all been tried. Anti-streptococcal serum, vaccines, and, more recently, transfusion have been employed but without success. The bad results of many of these methods of treatment has caused a great wave of conservatism to sweep the obstetrical world, and attention is now limited to increasing the patient's natural powers of resistance. The outdoor treatment of puerperal infection which was first advocated by Stone⁸ of New York, and Young¹⁰ of Boston, and later by DeLee⁹ has a decided value. At the Boston City Hospital¹⁰ following the introduction of the outdoor treatment the mortality of puerperal infection was reduced one-half.

Conservative Methods Indicated

If the present conservative methods fail to save a certain percentage of the cases of puerperal infection, there is little doubt that many of the measures enumerated, especially the surgical procedures, have increased rather than diminished mortality in the past. One of the hardest things an obstetrician has to do is to refrain from active treatment in a case of puerperal infection when he is convinced that active measures can do only harm. The family demand that something be done, and are satisfied if something is being done even if it takes away the patient's only chance. Only the most conscientious firmness and the greatest moral courage on the part of the obstetrician are sufficient to keep him from being driven into some injudicious surgical interference against his better judgment by the importunities of the patient's family.

¹⁰ Young and Williams, Boston Med. and Surg. Jour., 1912, clxvi, 40.

Eclampsia and allied conditions constitute the second most common cause of death in child-birth. Nevertheless there has been a great reduction in the mortality of these conditions. In 1906 Williams¹¹ quoted the maternal mortality of eclampsia as 20 to 30 per cent. These figures were certainly conservative for the lines of treatment followed at that time, which consisted of two extremes: the Stroganoff treatment with morphia in large doses and no attempt at delivery; and the *accouchement forc * with its high percentage of shock and rupture of the uterus. Young,¹² for the Boston City Hospital, shows a reduction from 36 per cent mortality for *accouchement forc * to about 25 per cent for cases treated by the induction of labor by the Vorhees bag. Similarly Cragin¹³ gives the following figures from the Sloane Maternity Hospital. In the first 20,000 cases delivered at the hospital there were 251 cases of eclampsia with 71 deaths, a mortality of 28.3 per cent. In the subsequent 15,774 deliveries there were 138 eclamptics with 20 deaths, or 14.5 per cent mortality. Cragin attributed this reduction in mortality to a change from *accouchement forc * to bag induction, combined with colon irrigations and the use of chloral by rectum.

The Handling of Eclampsia

In discussing the treatment of eclampsia at the present day it is no longer necessary to consider either the absolutely conservative expectant treatment or *accouchement forc * since both have been definitely discarded. There is one fact in connection with eclampsia which has been established beyond all question: that the condition is due directly to the presence of the fetus in the uterus, and that removal of the fetus always results in a cure unless death is due directly to the operative procedure by which the fetus is delivered, or unless a sufficient accumulation of toxins has already taken place in the maternal system to cause death even if the absorption of further toxins is prevented.

Only two methods of delivery need be considered seriously: the induction of labor by bag or bougie, and abdominal Cesarean section. A very small percentage of cases may perhaps be better delivered by vaginal Cesarean, but this does not enter into competition with the first two as a routine method. Unfortunately, no one operator has reported any considerable number of personal cases of eclampsia delivered by Cesarean section and our statistics are all therefore com-

posite, based upon the experience of a number of operators. Peterson¹⁴ collected reports of 283 recent cases of Cesarean section for eclampsia with a maternal mortality of 25.79 per cent. At first sight it would appear that Cesarean section does not compare favorably with bag induction as a means of delivery, but, when considered more carefully, it is apparent that there are certain types of cases where better results are to be expected from Cesarean than from the induction of labor. These types would be: (1) where age or pelvic contraction would lead one to expect a difficult delivery by the natural passages, and (2) where extreme haste is necessitated by the rapid progress of the toxemia. It is probable that the future will result in a sharp delineation of the boundaries within which lie the indications for each procedure.

Search for Toxic Principle

Further progress than can be made in the prompt recognition and delivery of these cases must await the discovery of the chemical substance or substances which constitute the toxins of eclampsia. Although investigators have not been idle in researches dealing with the chemical aspects of eclampsia, beyond demonstrating minor chemical changes in the blood they have not achieved important results. Plass¹⁵ demonstrated that in true eclamptics with liver changes there is little alteration in the nitrogen constituents of the blood, but in renal cases there is always a decreased total nitrogen while the relation of the non-coagulable nitrogen (urea, creatin, lecithin and ammonium salts) to the total nitrogen is decidedly increased. Plass has also demonstrated that creatin and creatinin pass to and from maternal and fetal circulation by diffusion.

Morriss¹⁶ studied the blood sugar with relation to placental interchange. He found that the blood sugar was normal in the first stage of labor and in pre-eclamptic toxemia but that following the muscular efforts of the second stage, or following a convulsion in eclampsia, it became increased. The fetal blood sugar at birth is lower than the maternal. Emge¹⁷ studied the acidity of the blood in normal pregnancy and in toxemias. He found a slight acidosis connected with normal pregnancy which is not increased in toxemia but is somewhat increased by muscular activity as in the second stage of labor and after eclamptic convulsions. This gives a rapid glimpse into one of the most fascinating fields for obstetric investigation which may one day lead to the isolation of the toxin of eclampsia.

Next in importance to sepsis and eclampsia as a cause of maternal death from childbirth come the accidentals of labor, especially rupture of the uterus. Only better obstetric training, and more careful conduct of labor, can be expected to reduce the incidence and therefore the mortality of these unfortunate mishaps. Next in frequency comes hemorrhage, especially hemorrhage from placenta praevia. There is a marked similarity in the obstetrical treatment of placenta praevia and eclampsia. In both instances delivery of the fetus from the mother is the foundation of treatment. In both conditions the same methods of delivery enter into competition, namely, induction of labor with bag and Cesarean section, save that in placenta praevia a third method, Braxton Hicks version, has also to be considered.

At the Seventh International Congress at London in 1913 Doderlein stated that in Bavaria from 1878 to 1907, there were 8,729 cases of placenta praevia, for the most part first attended by midwives, with a maternal mortality of 19 per cent. In a total of 5,615 cases collected from reports by obstetricians of different countries there was a mortality of 8 per cent. This he analyzed according to treatment as follows:

<i>Method</i>	<i>Cases</i>	<i>Mortality</i>
Simple rupture of membranes.....	309	1 %
Braxton Hicks version	1,434	8 %
Bag induction	777	6.5 %
Cesarean section	145	9 %

It is of course evident, as it was in the case of eclampsia, that no one treatment is applicable for all the cases. Given an uninfected patient, at the beginning of the hemorrhage, with a central, or in some instances with a partial, placenta praevia, with a child near term, and especially in the somewhat rare instances of placenta praevia in a primipara Cesarean section is almost unquestionably indicated; but it is comparatively seldom that the patient fulfills all these requirements. In the majority of the cases one of the other methods must be selected. Boyd¹⁸ in 8,697 deliveries at the Philadelphia Lying-in Charity Hospital found 59 cases of placenta praevia. Only two were delivered by Cesarean, with one death and one recovery. The remaining cases were delivered for the most part by tamponade followed by version or forceps with six deaths.

Cardiac Disease and Pregnancy

The importance of cardiac disease as a complication of pregnancy and labor has hardly been recognized, yet after the major obstetric complications just discussed it holds next rank as a cause of maternal death. The danger of a cardiac lesion depends in part upon the nature of the

lesion (all authorities agree that mitral stenosis is by far the most serious) and to a greater extent upon the degree to which the lesion is compensated. Newell¹⁹ believes that if a heart has become decompensated previous to the occurrence of conception that the heart can not stand the additional strain of pregnancy, and that the pregnancy in such a case should be terminated at once. In all cases in which there is a demonstrable cardiac lesion labor should be shortened to relieve strain on the heart. Kellogg²⁰ found in 30,000 pregnancies from 1 to 2 per cent of cardiac disease. He formulated a rather elaborate schedule for the treatment of these cases based upon the nature of the lesion. C. H. Lawrence²¹ believes that the presence or absence of decompensation is the only criterion upon which the treatment of such cases can be based.

Space forbids a discussion of the remaining causes of maternal death in pregnancy in labor. Many of them are accidental and inevitable, yet no doubt better medical treatment and more thorough study of these as well would result in a considerable reduction of the maternal death rate.

FETAL MORTALITY IN OBSTETRICS

Lobenstine²² estimated the percentage of stillbirths in New York City during the year 1916 as 4.61 per cent of the total births. The Women's Coöperative Guild of London²³, in a study of 348 families, found a history of 1,396 living children, 83 stillbirths, and 218 miscarriages. In other words, for every 100 pregnancies successfully terminated by the birth of a living child there were 21 $\frac{1}{2}$ which terminated in failure.

Miller²⁴ gives the following statistics for Philadelphia: He tabulated the stillbirths for a period of ten years from 1906 to 1916. The average yearly number of stillbirths due to injury at delivery was about 1.95 to every 1,000 births. In the year 1916 this figure rose to 3 per 1,000. The total stillbirths to total births varied from one in every 18.7 births in 1906 to one in every 27.2 births in 1916. He analyzed the causes of 100 stillbirths; 36 were due to prematurity, 4 to syphilis, 5 to birth injury, 3 to strangulation of the cord, 1 to hydramnion, and 1 to eclampsia. In the remaining 50 no definite diagnosis could be made on the information furnished.

The Wastage from Premature Birth

The wastage of infant life from premature birth is tremendous. Miller estimated the proportion of premature to total births as from 1.69

¹⁸ Boyd, Am. Jour. Obst., 1917, Ixxvi, 26.

¹⁹ Newell, Jour. Am. Med. Assn., 1912, Ix, 1147.

²³ Maternity, London, 1915.

²⁴ Miller, Am. Jour. Obst., 1917, Ixxvi, 615.

to 1.64. The reviewer has been struck with a similar experience at the Boston City Hospital obstetric ward. In 367 births during the year 1918, he found 93 premature, among which 48 died at birth or before leaving the hospital, i. e., 25 per cent of total births premature and 50 per cent of prematures died.

The influence of syphilis as a cause of stillbirth has long been recognized and may be accepted as accounting for a large percentage of the stillbirths occurring after a normal labor. Chronic nephritis is also a prolific cause of fetal death *in utero*. The fetal death rate in eclampsia is variously given as 33 per cent by Young¹², 44.9 per cent by Cragin¹³, 19 percent by McPherson²⁵, and 30 to 60 per cent by DeLee²⁶. It is doubtful if this fetal death rate in eclampsia will be greatly reduced until the chemistry of the toxemia is more fully worked out as the babies delivered from eclamptic mothers are usually premature and always more or less toxic. Placenta praevia also has a high fetal death rate, the issue in the individual case depending chiefly upon three factors: the period of pregnancy, the amount of hemorrhage, and the method of delivery. Doderlein* in the 8,729 Bavarian cases found a fetal mortality of 50 per cent. In his collected series of patients treated by obstetricians he found that the fetal mortality varied from 25 per cent in the cases which could be treated by simple rupture of the membranes, 30 per cent in those delivered by Cesarean section, 45 per cent in those delivered by induction of labor, to 74 per cent where Braxton Hicks version was employed. Boyd¹⁴ in 59 cases at the Philadelphia Lying-in Charity Hospital had a fetal death rate of 79 per cent, but only 50 per cent of the babies delivered were viable anyway. It is hard to see how the fetal mortality in placenta praevia can be greatly improved. The very character of the condition imperils the child's life even sooner than the mother's.

Placental Bacteriemia and Stillbirth

Attention is now being drawn to placental bacteriemia as a cause of stillbirth. The infectious abortion of cattle had been recognized as a specific infectious disease even before Bang²⁷ in 1897 isolated the *bacillus abortus* and demonstrated it as the infecting organism. The symptoms of this disease which occurs in epidemics are those of septicemia associated with the death of the fetus *in utero*. The death rate of the mothers as well as of the embryos is very high. There is no evi-

dence that the *Bacillus abortus* is pathogenic for human beings, although DeForrest²⁸ reported 11 cases of stillbirth in women with symptoms suggesting the infectious abortion of cattle, and who during their pregnancies had been more or less directly exposed to surroundings in which there had been cattle sick with disease. In one case a bacteriological examination was made but the *Bacillus abortus* was not found.

Slemons²⁹ has studied the histological picture of the placenta in 34 cases of placental bacteriemia. Typically the bacteria are found in the subamniotic connective tissue sinuses where they come in contact with the fetal vessels which cross the placenta. It was occasionally possible to demonstrate the bacteria in the act of penetrating the walls of the vessels. In most cases the epithelium of the villi was intact. The capillaries in the villi did not contain bacteria. It is thus evident that infection did not proceed from the maternal circulation. The bacteria enter the placenta by way of the amniotic membrane and amniotic fluid. Generally the latter becomes infected because the membranes rupture prematurely, labor is prolonged, and repeated vaginal examinations are made. As placental infection is usually limited to the amniotic surface of the placenta, this complication is more serious for the infant than for the mother. Not infrequently such infection of the fetus leads to its death either before or soon after birth. Slemons believes that placental bacteriemia is out-ranked only by syphilis as a cause of fetal death. In one series of 100 labors placental bacteriemia was noted 24 times. Elevation of temperature is always significant of placental bacteriemia.

Cornell³⁰ reported an interesting case in this connection. The patient, a quadripara, age 29, had been delivered of a breech, living baby, at end of her first pregnancy. The second and third were stillborn, cause unknown. Being pregnant for the fourth time fetal death *in utero* was diagnosed. Culture taken from the cervix uteri at this time showed staphylococci, a Gram-positive diplococcus resembling streptococcus viridans, and diphtheroids. Cultures from the throat showed occasional staphylococcus and streptococcus viridans. Culture from the teeth showed staphylococcus-streptococcus viridans, the usual anaerobes, bacillus fusiformis, diphtheroids and streptococci. Three weeks later a macerated fetus was delivered. The fetus and placenta were examined bacteriologically. The placenta showed Gram-negative bacilli, and spore-bearing Gram-positive bacilli, both saprophytic. Similar organisms were

³⁰ Cornell, Illinois Med. Jour., Springfield, 1918, xxiv, 266.

found in the liver and body fluids. In the latter, diphtheroids were also found but no streptococci and no spirochaetae.

The mother made a good recovery, having no temperature higher than 99.5. The fetal death was undoubtedly due to placental bacteriemia, but Slemmons' conclusions that infection enters through the amniotic surface of the placenta can hardly hold true here. Nevertheless, an important cause of stillbirth has been recognized, and further study will no doubt result in measures for its control.

Mechanical Injuries in Labor

After the consideration of fetal deaths due to disease in the fetus or mother we next come logically to the fetal mortality the result of mechanical injury during labor. The reviewer³¹, in 1916, collected the reports of the results of delivery by the intrapelvic operations, forceps, version, etc., in eight clinics. In a total of 2,936 such operative deliveries there was a fetal mortality of 17.2 per cent. To overcome the dangers of these hard intrapelvic deliveries to the child the operation of Cesarean section was devised over three centuries ago and first performed so far as we know by Trautmann, of Wittenberg. Cesarean section, while, accident excepted, guarantees a living child, has a definite maternal mortality. This mortality in certain cases is a decidedly high one. Therefore, other operations have been devised to overcome the danger incident to Cesarean section in late and infected cases: pubiotomy and the extraperitoneal Cesarean section. The consideration of these operations therefore, may be properly taken up under the general subject of infant mortality since they are all designed to reduce it.

Dangers of Cesarian Section

If the maternal mortality of Cesarean section were zero, all cases where the forces of nature fail would be delivered by Cesarean, thus saving all the babies, and this part of the problem would be solved. The reviewer, in the paper above mentioned, collected also the reports of 849 Cesarean sections done under favorable conditions with a maternal mortality of only 1.6 per cent. On the other hand, Newell³² collected the results of Cesarean section in various New England cities where the operation had been performed on badly selected cases and by inexperienced operators. He concluded that the actual mortality was about 10 per cent. Rongy³³ reported 109 personal cases with a mortality of 7 per cent, but his cases were for the most part consultation cases done after

failure of the natural forces, and included some eclamptics which should not be considered properly in this place.

To reduce the dangers of Cesarean section in late and infected cases the extraperitoneal operation was devised by Frank in 1906 and modified by Sellheim in 1907. According to Nicholson³⁴, there are now about twenty different techniques for the extraperitoneal operation. These may be subdivided into (1) transperitoneal operations in which the peritoneum is opened, stripped off the anterior surface of the lower segment of the uterus and the uterine peritoneum united to the parietal peritoneum before the uterus is opened; and (2) true extraperitoneal in which the approach is made through the pelvic cellular tissue at the side of the bladder, without going through the peritoneum. As a matter of fact, the peritoneum is very frequently opened in the attempt to operate by this latter method. In 255 cases collected up to 1916³⁵, the maternal mortality was 3.5 per cent, which was good considering that in most of these the classic Cesarean was contraindicated by long labor or infection. De Lee³⁶ has obtained the most recent figures. He sent out a questionnaire to ten well known operators. In reply he received statistics of 39 true extraperitoneal operations with 4 maternal deaths, and 117 transperitoneal with 1 death. Reusch³⁷ collected 595 European cases with 2 per cent mortality.

Methods of Pubiotomy

Pubiotomy has never been received with enthusiasm in America. Jacobson³⁸ in 1912 was able to collect only 53 American cases. Recently Williams³⁹ has reported a series of 43 operations performed at the Johns Hopkins Hospital on 40 women without maternal death. The semi-subcutaneous method of Doderlein was used after a prolonged test of labor in the second stage. The operation was restricted to patients presenting moderate degrees of pelvic contraction, the smallest pelvis having a *conjugata vera* of 7 cm. In one-half of his cases there were vaginal tears, and in two bladder injury. He tries for fibrous rather than bony union in order permanently to enlarge the pelvis. The increase he found was greatest in the transverse diameter of the outlet which makes the operation of most value in funnel pelvises. Twenty of his 40 patients were subsequently delivered by the natural passages without difficulty, their pelvises being permanently increased in size. Eleven pelvises were markedly enlarged, the aver-

³¹ Rongy, Am. Jour. Obst., 1918, Ixxviii, 840.

³⁴ Rensch, Zentralbl. f. Gynäk., xli, 595.

³⁵ Jacobson, Surg. Gynec. and Obst., 1912, xv, 213.

³⁶ Williams, Am. Jour. Obst., 1915, Ixxii, 1.

age increase being 1.8 cm. in the transverse diameter of the outlet. In several pelvies not only were the diameters increased, but the shape was also changed.

Jellett⁴⁰ has recently advocated what he calls "The Radical Cure of Pelvic Deformity" by which he means performing pubiotomy in advance of labor or even in advance of pregnancy. I mention this in order to condemn it. It is universally admitted that pubiotomy should be restricted to moderate degrees of pelvic contraction. It is also a well known fact that labor terminates spontaneously in 75 to 80 per cent of such pelvies (Williams⁴¹) so that if one performs pubiotomy in advance of labor in all cases of pelvic contraction, the operation will be done needlessly in 75 to 80 per cent. Jellett reported 35 pubiotomies from the Rotunda Hospital with two deaths. Eleven of these patients were subsequently delivered of living babies by forceps, version, or normal labor, testifying to the permanent increase in the size of the pelvis, but not justifying the wholesale performance of the operation without a test of labor. The problems of the obstetrician are not ended with the birth of a living child. Ballantyne⁴² has shown that one-third to one-half of the children dying under one year of age die during the first month, during which time they are ordinarily under the care of the obstetrician. McConnell⁴³ states that in Glasgow from 1909 to 1912 the death rate of infants during the first four weeks was 44.33 per 1,000 live births. Upon scarcely any subject in medicine has so little thought been expended as on the infant mortality during the intrauterine period and the first four weeks of life.

INFANT MORBIDITY

From a purely economic standpoint the birth of a child free from injury is of even greater importance than the birth of a living child, for a dead or stillborn child is a loss to the state but a child crippled either physically or mentally is not only a loss but also a liability.

Frazier⁴⁴ believes that 30 per cent of all children who recover from cerebral hemorrhage at birth develop epilepsy later in life. Mouser⁴⁵ found that 17.64 per cent of his cases of epilepsy had a history of difficult birth. In cases of idiocy he found that 11.6 per cent had a history of difficult birth. Shuttleworth⁴⁶ put the figure at 29 per cent.

⁴⁰ Jellett, *Surg., Gynec. and Obst.*, 1919, xxix, 117.

⁴¹ Williams, *Surg., Gynec. and Obst.*, 1917, xxv, 194.

⁴² Ballantyne, *Monthly Bull. Mass. State Dep. Health*, 1919, vi, 166.

⁴³ McConnell, *Brit. Med. Jour.*, 1918, ii, 365.

⁴⁴ Frazier, *Progr. Med.*, 1907, i, 24.

⁴⁵ Mouser, Quoted by Porter, *Jour. Am. Med. Assn.*, 1909, lii, 937.

⁴⁶ Shuttleworth, *Brit. Med. Jour.*, 1886, i, 183.

⁴⁷ Stein, *Jour. Am. Med. Assn.*, 1917, lxix, 334.

Stein⁴⁷ discussed in an admirable article the influence of labor on the brain development of the child. He said: "Instrumental delivery, more particularly by the obstetric forceps, has often been accused of being the cause of birth traumatism, and has undoubtedly caused serious mutilation in the hands of the unskilled; but its action can never be so prolonged or profound as the moulding of the soft cranial bones in very narrow or otherwise obstructed pelvic passages."

Difficult Labor and Mentality of Child

Difficult labors cause damage to the child's brain through three mechanical processes: (1) direct contusion of brain substance; (2) local congestion and rupture of the intracranial vessels by over-riding of parietal bones; and (3) general congestion of the venous system resulting in capillary hemorrhage.

Stein concluded that (1) prolonged labor is responsible for much harmful compression during labor; (2) the damage results in the production of all degrees of mental impairment from feeble-mindedness to idiocy. (4) In the interest of the prevention of idiocy better records should be kept of the conditions during labor and the subsequent mental development of the children. Obstetric forceps, correctly applied, are less dangerous than the prolonged passage of the child's head through the pelvic canal.

Goddard⁴⁸ says that since many normal children are delivered with the use of instruments and the temporary deformity of the head is without effect on mentality, it is unreasonable to conclude that where there is both hereditary feeble-mindedness and a history of instrumental delivery that the instruments were the cause of the mental deficiency.

Sachs⁴⁹ found idiocy present in 60 per cent of paraplegias, and 13 per cent of hemiplegias. He described the case of a child born after a hard, dry labor and presenting symptoms of mental impairment. The child died when a year old and autopsy showed adherence of the pia over the frontal halves of both hemispheres.

Fletcher Beach⁵⁰ found a history of prolonged parturition in 27.28 per cent of idiocy, but in only 3.3 per cent were forceps used. In the Darenth Asylum for Imbecile Children, among 810 cases of idiocy there were 4.3 per cent who had been delivered by forceps, but 26.6 per cent had been delivered normally after a prolonged labor. König⁵¹, in 260 cases of simple idiocy, found 39 cases of difficult birth, all but five of which were spontaneous, however.

⁴⁷ Goddard, *Feeble-mindedness, Its Causes, etc.* N. Y., 1914, 447.

⁴⁸ Sachs, *New York Med. Jour.*, 1891, iii, 503.

⁴⁹ Beach, *Lancet*, London, 1889, i, 97.

⁵⁰ König, *Allg. Ztschr. f. Psychiat.*, 1904, xlii, 133.

From these various figures quoted it is apparent that, after hereditary causes, difficult delivery forms a large etiological factor in mental impairment. It is not evident, however, that traumatism with the obstetric forceps has been the cause of such cerebral injury, but rather the prolonged pressure of the child's head against the pelvis. The earlier employment of the obstetric forceps would perhaps have prevented many of these cases; but the real aim of the obstetrician should be to anticipate these difficult deliveries by the early performance of Cesarean section when it is apparent that labor will be prolonged and difficult.

While less serious from an economic and humanitarian point of view, since it is not connected with any mental impairment, but of very great importance, since it partially cripples the unfortunate subject, injury of the brachial plexus during delivery deserves serious consideration. Thomas and Sever⁵¹ give an excellent summary of previous work on this condition together with their own experience. They conclude that in the great majority of cases the paralysis is due to injury of the brachial plexus by stretching. They reject absolutely the theory of Gaugele⁵² that birth palsies are not true paralysis, but due to injury of the capsule of the shoulder joint with subsequent contractures. In 109 x-rays taken in Thomas' clinic only one fracture each of the clavicle and humerus were seen in obstetrical paralyses. The stretching of the brachial plexus which produces the paralysis may result from the delivery of extended arms when the fetus presents by the breech or, more commonly, because vertex presentations are more common, results from difficulty in freeing the shoulders after birth of the head. This difficulty is the result, in the reviewer's experience, of resistance from a contracted outlet with a v-shaped arch or, less commonly, from a contraction ring closing down about the neck after birth of the head. The anterior shoulder is practically always the one affected.

When such paralysis occurs the child should be at once put under the care of a competent neurologist, as Thomas has shown that in nearly all cases the muscles gradually recover voluntary control and, if contractures can be prevented and re-education of the paralyzed muscles carried out, function can in most cases be restored.

MATERNAL MORBIDITY IN OBSTETRICS

It may be stated without fear of contradiction that the maternal morbidity in obstetrics de-

creases in direct proportion with the amount and quality of the care bestowed upon the patient before, during, and after labor. Prenatal care is of comparatively recent origin. Postnatal care, extending beyond the hospital period of two weeks at most, is even yet limited largely to the well-to-do private patients. While all well equipped maternity hospitals in the large centers have prenatal clinics, these care for only a small part of the women of the world and it may be of interest to review such beginnings as have been made toward the extension of prenatal care to less fortunate districts.

Belt⁵³ has contributed an interesting article on this subject especially in regard to work done in England, France, and Germany during the war. July 30, 1914, the Local Government Board for England and Wales issued circulars in regard to grants which would be made by it for maternity work, offering to county councils and sanitary authorities one-half the expense of carrying on the following work:

1. Arrangements for the local supervision of midwives.
2. Arrangements for antenatal clinics, antenatal home visits, and maternity hospitals for the care of complicated cases of pregnancy.
3. Arrangements for skilled assistance during confinement, if necessary in a hospital.
4. Arrangements for the treatment in a hospital of complicated cases after confinement, systematic infant clinics, clinics for young children, and systematic visitation of the homes of infants and young children.

In 1915 and 1916 the same offer was made. In a majority of the districts some child welfare work is done and some maternity centers are under way, but no prenatal work has been done as yet except by private agency.

In Paris during the year 95 per cent of the women were delivered by public aid, not necessarily by midwives. In Germany 90 per cent of the women were delivered by midwives. In America there is no real midwife problem for, while the immigrant women are in large number attended by midwives, the generation of women who have been born here and educated in the public schools will not tolerate the midwife, and the midwife will automatically disappear.

Maternity Benefits from the State

The subject of maternity aid from the state has aroused much discussion. Belt states that the national insurance acts in England passed in 1911

⁵¹ Thomas and Sever, Jour. Nerv. and Ment. Dis., 1916, xlii, 289.

⁵² Gaugele, Ztschr. f. Orthop., Chir., 1914, xxxiv, 511.

⁵³ Belt, Am. Jour. Obst., 1918, lxxvii, 174.

and 1912 allow two maternity benefits of thirty shillings each, the second one payable only if the woman refrains from work outside her home for four weeks following confinement. The French maternity grants allow 10 to 25 cents a day over a period of eight weeks. Maternity benefits established in Germany in 1911 allow \$5.95 toward the expense of the confinement, 24 cents a day for eight weeks, six of which must be after the confinement, \$2.38 prior to the confinement for midwife or doctor, and premiums of 12 cents a day until the twelfth week for nursing mothers.

In this connection the investigations of Deacon⁵⁴ into the employment of pregnant women in munition factories are of interest. In one factory he found 101 women employees pregnant. At the time of his report 46 had terminated successfully, 34 were still pregnant but 19 were later delivered without trouble, the remainder being still pregnant. Only two premature births were reported and of these one mother had syphilis and the other carcinoma. There were 13 early abortions, no more than the usual proportion under ordinary circumstances.

After Care in Maternity Cases

Too little has been done to follow up the treatment of minor complications of childbirths, such as small lacerations, prolapses, subinvolution, etc., until the patient is restored as nearly as possible to a state of efficiency equal to that before confinement.

The New York Lying-in Hospital has established a clinic for the after care of its patients. Every obstetric patient of the hospital is given a card to this clinic on discharge and told to report to it. Smith⁵⁵ reports observation made in this clinic over a period of one year; 289 patients returned to the clinic for advice or treatment. During the first month 81 patients reported, the most common disorders being subinvolution, unhealed perineal lacerations, hemorrhoids, and retroversion; 92 patients came back during the second month after delivery. Here troubles with the breasts and nipples, subinvolution, rectal disturbances, perineal lacerations and back-strain predominated. Thirty-eight patients presented themselves during the third month after delivery; the most common complaint among these was retroversion. In the fourth month 39 patients presented largely adnexal and perimetric conditions. In the fifth and sixth months 39 patients returned for the most part concerned over a possible diagnosis of pregnancy.

There is some difference of opinions to how

much immediate repair work should be undertaken at the time of delivery or during the puerperium. Most obstetricians and all general practitioners confine repair work at this time to the immediate suture of perineal lacerations. A very few, like Skeel⁵⁶, advise the repair of every tear of the genital tract immediately after labor and report excellent results. The arguments against such procedures are the difficulty of technic, which can be overcome by proper assistants and good illumination, however, and the fact that much of the damage done in delivery is not in the form of clean cut lacerations but rather in subcutaneous rupture of fascial bands and muscle fibers, and, furthermore that failure of involution results in more permanent harm than unsutured lacerations.

The work of Hirst⁵⁷, however, who has for many years done what he calls the *intermediate* repair of lacerations, is deserving of consideration. He does not attempt to repair lacerations immediately after labor, but in those patients who require repair he operates one week after delivery, at which time the edema of the parts has gone down, the tissues can be approximated perfectly, and the lochial discharge has diminished sufficiently so that the operation can be conducted without having the field constantly obscured by blood. The argument against this method is purely one of expediency but, unfortunately, one which is very powerful, namely, that few patients will consent to such an operation one week after having gone through the exhaustion and suffering of labor.

Conclusion

The perusal of the foregoing review can not fail to impress the reader with the vast amount of work remaining to be done before the present day problems in obstetrics shall be solved. In spite of the vast benefit which has resulted from the introduction of asepsis and anesthesia in obstetrics, and, admitting the undoubted advances of recent years, our results are still far from perfect and a wide field of investigation, including not only problems for the obstetrician, but for the chemist, the pathologist, the sociologist, and even the legislator lie open to the future.

THIRD HOSPITAL SURVEY BEING MADE

A reliable list of hospitals which can furnish a satisfactory intern training is the immediate end sought for by the American Medical Association in its third survey of hospitals, which is now being made. A mass of information on the subject has been obtained by the Association through wide-spread correspondence and a questionnaire. This data is being carefully checked.

BOOKS OF THE MONTH

Comment on Current Medical and Health Literature and Announcements of New Books

PERSONAL HYGIENE AND HOME NURSING. A practical text for girls and women for home and school use. By Louisa C. Lippitt, R.N., assistant professor of corrective exercises, University of Wisconsin.*

This small book is an admirable guide for those interested in the care of the adolescent girl. The articles are well written and are based on accepted principles of rational hygiene.

It should prove an excellent text for use in secondary schools and colleges.

HYGIENE FOR NURSES. By Nolie Mumey, M.D., lecturer in hygiene, chemistry, and bacteriology, Logan H. Roots Memorial (City Hospital) Training School; assistant instructor in surgical technic, University of Arkansas; resident physician of City Hospital and a member of the visiting staff, Little Rock, Ark.†

We fail to see the particular value of this book among the already too numerous works on the subject. It will hardly find a favorable reception in the better training schools owing to many of its inaccurate phrases, such as, on page 380, "bacteria alone are responsible for all of our diseases" or, on page 40, "Jews are immune from tuberculosis."

The printing is clear and there are a few good pictures, but the book necessitates a thorough overhauling before it can be conscientiously recommended as a reliable text book.

THE DIAGNOSTICS AND TREATMENT OF TROPICAL DISEASES. By E. R. Stitt, A.B., Ph.G., M.D., LL.D., Rear Admiral, Medical Corps, United States Navy; Commanding Officer and Head of Department of Tropical Medicine, United States Naval Medical School; graduate London School of Tropical Medicine; professor of Tropical Medicine, Georgetown University; professor of Tropical Medicine, George Washington University, etc.‡

The popularity of this text is justly shown by the complete exhaustion of the second edition which appeared less than a year ago. This new edition does not contain any material changes, these having been made in the second edition.

The paragraph on Trench Fever has been rewritten so that it covers the work of the English and American Commissions which quite clearly showed the exact etiology of the disease and its clinical manifestations. In addition to minor changes in other paragraphs a plate of benign tertian, quartan and malignant tertian, malarial parasites has been appropriately added. An illustration of *D. andersoni* has been inserted in the paragraph on Rocky Mountain Fever.

This edition will undoubtedly be as popular as the former ones, which well indicates the value of the book.

OCCUPATIONAL THERAPY APPLIED TO RESTORATION OF FUNCTION OF DISABLED JOINTS. By Bird T. Baldwin, Major, S.C., U.S.A. Director of Occupational Therapy and Chief Psychologist Walter Reed General Hospital.§

This work is a preliminary report on the aim, scope and methods of one phase of occupational therapy as worked out inductively at the Walter Reed Memorial Hospital.

Occupational therapy is defined as a purposeful, remedial activity adapted to each particular case, and directly encouraging voluntary efforts and personal initiative on the part of the patient. The workshop type of therapy has an added value in that the patient constitutes a part of a social group and the product of his activities has an economic value, which is encouraging and inspiring to the patient.

MILK. By Paul G. Heineman, Ph.D., director of the laboratories of the United States Standard Serum Company, Woodworth, Wis.||

Despite the fact that the author does not claim to have treated the subject exhaustively, he must be given credit for producing the most complete and comprehensive volume on milk that has been published in the English language up to date.

The text might well be styled a so-called "Handbuch," for it contains most valuable and accurate information for all persons interested in milk, no matter what that interest might be, ranging from producer, inspector, on to consumer.

For the laboratory worker the text is of great value for the various chapters, which are excellently arranged, are quite complete from a historical standpoint, continuing through the physiology of lactation, physical and chemical properties of milk, and several chapters of bacteriological subjects relating to milk. A detailed description of the technical methods for the physical and chemical examination of milk are very clearly given. The author has judiciously selected the better methods and these are so described that the laboratory worker will have little difficulty in the interpretation and correlation of results.

The chapters of interest to bacteriologists are very complete, covering the sources and kinds of micro-organisms in milk, fermented milks, the bacteriological examination of milk and milk-borne infections. This latter chapter depicts in a rather decisive manner the various infections that are milk-borne, and shows their relative importance and rôle in daily health work and control. Methods for certifying, pasteurizing, and reducing the germ content of milk are also given.

The chapter on the control of milk supplies is quite

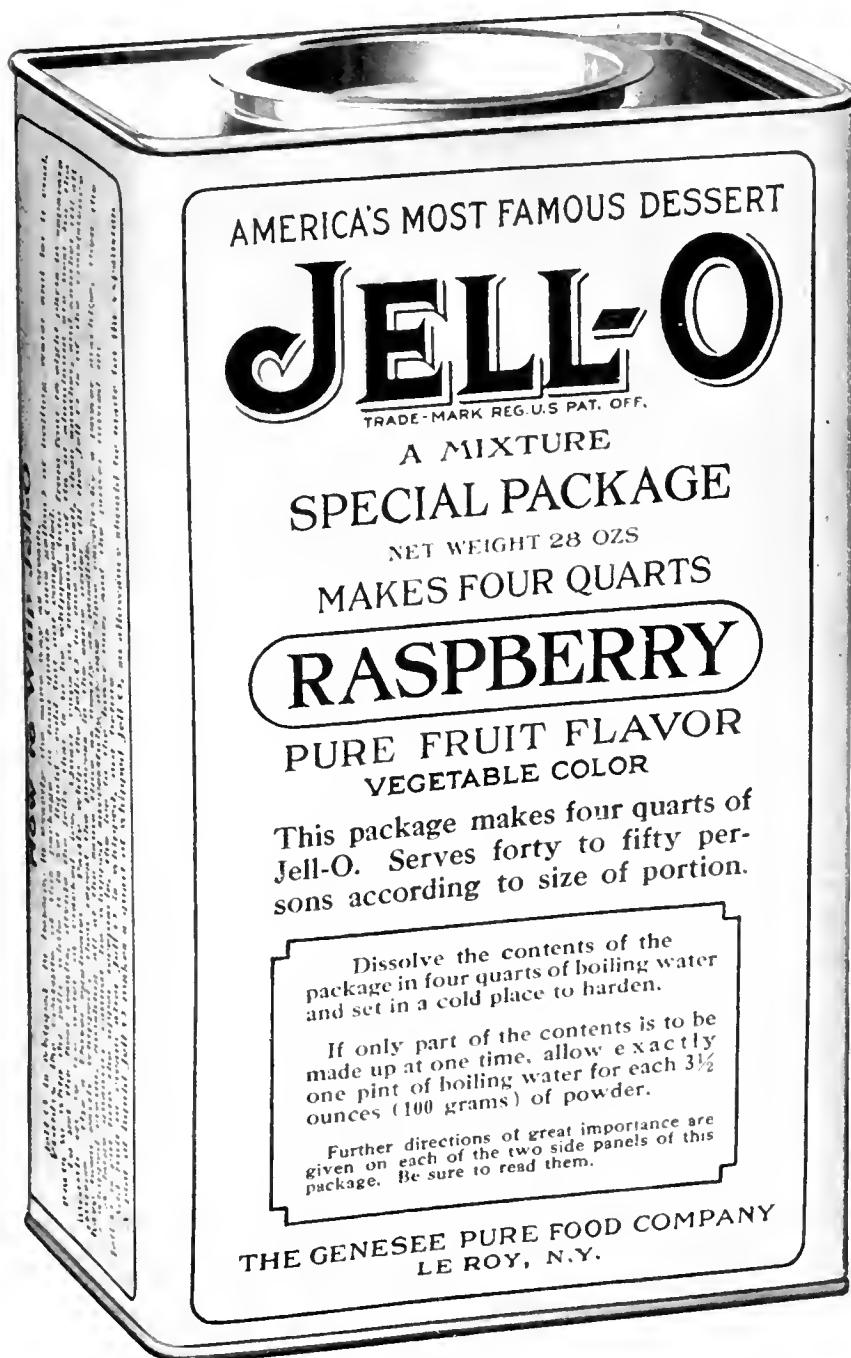

(Continued on Adv. Page 22)

The Special Size for Hospitals

One gallon instead of one pint of Jell-O is made up from the new Special Package of Jell-O, saving nine-tenths of the time required for opening and emptying the common small size.

This change eliminates the last remaining bit of real work connected with the preparation of Jell-O dishes.

The Strawberry, Lemon, Orange, Raspberry and Cherry flavors are made in this special size regularly and the Chocolate flavor when desired.

SUBSCRIPTION

Domestic postage, \$3.00. Foreign postage, \$3.50 (15 shillings). Single copies (regular), 25 cents.

Domestic rates include United States, Cuba, Mexico, Porto Rico, Canal Zone, Hawaii, and Philippines.

SUBSCRIPTIONS.—Subscriptions may begin at any time. Volumes begin January except in the case of Volume I, which consists of the numbers issued during 1919 (May to December, inclusive).

REMITTANCES.—Remittances for subscriptions should be made by check, draft, post office or express money order, or registered letter. Make all checks and money orders payable to MODERN MEDICINE.

CHANGE OF ADDRESS.—Notice of change of subscriber's address should give both old and new addresses. Notice should reach us fifteen days in advance of date of publication.

COMMUNICATIONS.—When communications relate to more than one subject (manuscript, reprints, subscriptions, news items, etc.), correspondents will confer a favor by writing on a separate sheet for each subject, thereby insuring more prompt attention.

ADVERTISEMENTS.—The advertising pages of MODERN MEDICINE are available for announcements of anything of interest and service to those engaged in the treatment and care of the sick and especially to those who are devoting their efforts to organized medical and health work. Advertisements of secret remedies and other objectionable announcements will not be accepted. The supervision of the Editors is extended to the advertising columns, in which only approved products and reliable manufacturers will be represented.

CLOSING OF FORMS.—Advertising forms close on the 10th for the issue of the following month. Ample time should be allowed for composition of advertisements and the sending and return of proofs.

ADVERTISING RATES.—Advertising rates will be sent on request.

CONTRIBUTIONS.—Original articles on any problems of practical interest to our readers are respectfully solicited from those who can write authoritatively on current problems in social medicine, hygiene and medical service in industry, public health and allied subjects. Articles are accepted for publication with the understanding that they are contributed solely to MODERN MEDICINE.

ILLUSTRATIONS.—Such half-tones and zinc etchings as in the judgment of the Editors are necessary to illustrate articles will be furnished when photographs, drawings, or ink tracings are supplied by the author.

NEWS MATTER.—Our readers are requested to send in items of news, and also marked copies of newspapers containing matters of interest. We shall be glad to know the name of the sender in every instance.

SUBSCRIPTION BLANK

BOOKS OF THE MONTH

(Continued from Page 740)

valuable for sanitarian, health officer, and laboratory worker, the last especially, for he can readily obtain an idea of the magnitude of work of this nature and better equip himself to be of the maximum aid in this rather difficult and trying phase of milk handling.

The chapters of interest to the producer, consumer, economist, and student are all of a nature that greatly enhances the value of the book. In fact, anyone having an interest in milk and its products will find the text to be most serviceable to them. Dr. Isaac C. Abt and Abraham Levinson have contributed a most valuable chapter on milk and its relation to the importance of infant feeding, which will be greatly appreciated by most readers.

The author has appended each chapter with a very representative bibliography and the text is profusely illustrated. The book has been so written as a result of the author's experience as a teacher and investigator, and contains such practical first hand knowledge that it well deserves to be in the possession of anyone having an interest in the subject of milk.

DISEASES OF OCCUPATION AND VOCATIONAL HYGIENE. By George M. Kober, M.D., LL.D., and William C. Hanson, M.D.*

When a book contains as much good material as is present in this volume, the reviewer should be satisfied with beginning and ending his review by the statement that it is an excellently well done and serviceable work. However, to do justice to this book it is only fair to state that it contains practically all that is known of this most interesting subject and that the contributions are by men of accepted reputation in the lines on which they write. The prefatory remarks give a brief historical review of the high lights in the development of interest in occupational and vocational diseases with a special division devoted to the progress of industrial hygiene in the United States. The aim of the editors has been the presentation of the basic data concerning the diseases of occupation in such a way as to render them available not only to physicians but also to employers, employees, efficiency experts, public health officers, and legislators. The book is divided into three general parts, dealing first with the specific and systematic diseases of occupation, second with the etiology and prophylaxis of occupational diseases, and, third, with the legislation and governmental study for the prevention of occupational diseases. The reader can look up lead poisoning, the method of preventing lead poisoning, and the legislative and other measures that have been framed to control lead poisoning. He can look up the dangers of any particular industry. He can study the health of women wage earners. He can get the symptoms of any form of poisoning. In fact, he can get almost everything he wants from this book.

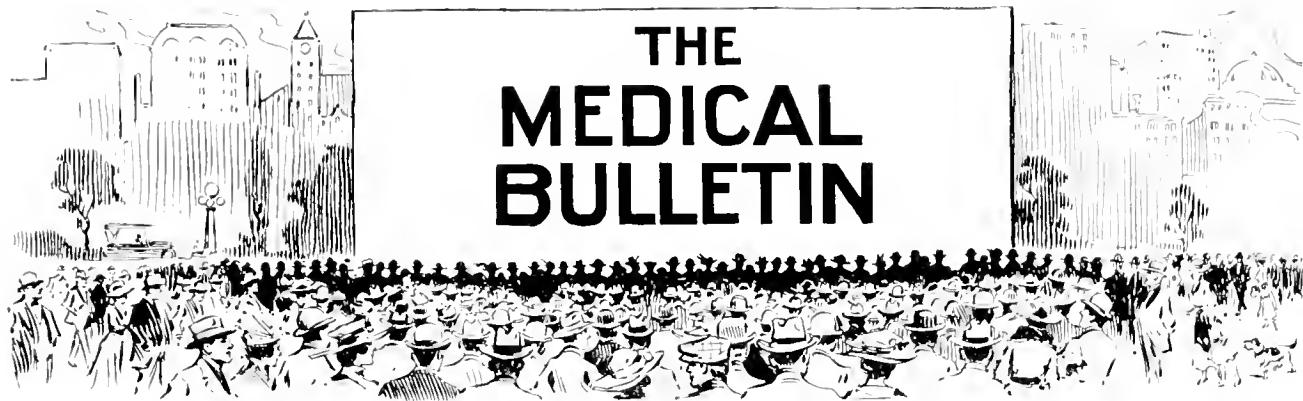

MENDERS OF THE MAIMED. The Anatomical and Physiological Principles Underlying the Treatment of Injuries to Muscles, Nerves, Bones, and Joints. By Arthur Keith, M.D., F.R.C.S., LL.D.†

Keith, in his delightful book, "Menders of the Maimed," has endeavored to re-state the principles upon which our knowledge of orthopedics is based. He has presented these principles from an historic aspect. The book contains biographical sketches of John Hunter, H. O. Thomas, Mar-

THE LUIKART CHILDREN

Carter's Mercury Antidote

The recent publicity given the Luikart children of Detroit, poisoned by corrosive sublimate administered by their mother, and saved from death through the timely help of Dr. Thomas A. Carter, of Chicago, must impress on every physician the advisability of having a supply of Doctor Carter's antidote on hand for such emergencies. The administration of Carter's antidote is very simple—one tablet being given for each tablet of the poison taken. It is supplied in bottles of 100 and 500 tablets by The Abbott Laboratories.

Incidentally, the too-numerous cases of poisoning with bichloride must lead one to consider the use of an antiseptic having all the virtues of bichloride, phenol, and such substances without their poisonous qualities. Such an antiseptic is Dakin's stable, water-soluble, non-irritating synthetic Chlorazene.

The latest form in which Chlorazene has been produced, and we believe ultimately the most popular, is

AROMATIC CHLORAZENE POWDER

This is a combination of 5% of Dakin's Chlorazene with sodium bicarbonate, sodium chloride, saccharin, and eucalyptol. A teaspoonful of this powder dissolves instantly in a glass (about 6 ounces) of water and produces a delightful aromatic antiseptic solution, which is $2\frac{1}{2}$ times as strong as pure carbolic acid. It makes an agreeable and powerfully germicidal mouth-wash, spray for nose or throat, gargle, or douche. It is cooling, refreshing, and of great germicidal power. It may also be used for general antiseptic purposes, such as applications to cuts, wounds, skin diseases, etc.

A FREE TRIAL BOTTLE OF AROMATIC CHLORAZENE POWDER

The coupon below
will bring it to you.

AIDS TO SUCCESSFUL SURGERY

The development of remarkably improved germicides—Dakin's Chlorazene and Dichloramine-T together with a new type of non-sticking wax-impregnated dressing—Parresined Lace-Mesh Surgical Dressing—makes possible a procedure for wound treatment which is giving remarkable results.

First: CLEAN OUT by excision of all devitalized tissue and by removing all dirt with Neutral Sodium Soap, Abbott, the non-irritating, alkali-free liquid soap made from vegetable oil.

Second: CLEAN UP all existing infection by irrigating with Chlorazene, Dakin's powerful, non-irritating, water-soluble antiseptic. The wound is then dried and sprayed with solution of Dakin's Dichloramine-T in Chlorcosane, the most powerful germicide known to science, accomplishing in $\frac{1}{2}$ minute the same degree of sterilization which it takes 7 hours for bichloride or 24 hours for phenol, to produce. The antiseptic action of Dichloramine-T-Chlorcosane is prolonged over 18 to 24 hours, requiring dressings only once daily, and cleaning up infection at a very rapid rate.

Third: KEEP CLEAN—Prevent reinfection by daily dressings with Dichloramine-T-Chlorcosane and protect with Parresined Lace-Mesh Surgical Dressing. This wax-impregnated woven lace DOES NOT STICK and is painlessly removed without disturbing the healing processes.

RETURN THIS COUPON

The Abbott Laboratories, Dept. 27, Chicago, Ill.

You may send me, without charge, a trial bottle of AROMATIC CHLORAZENE POWDER. Also information regarding Dichloramine-T, Parresined Lace-Mesh Surgical Dressing, and Neutral Sodium Soap.

BOOKS OF THE MONTH

(Continued from Page 22)

shall Hall, and others,—men who blazed the trails in orthopedic surgery. Each chapter describes, moreover, the manner in which the fundamental ideas in orthopedics have been developed. It pleases us to learn that John Belchier accidentally discovered the vital bone-staining properties of madder while dining at the home of a calico maker, who economically fed his pigs with the madder-stained bran of his dye works, and then fed his guests with these pigs. We are interested in seeing how Duhamel, John Hunter, and others used this discovery of Belchier to build up our present knowledge of osteogenesis. In a similar manner Keith describes the development of other modern theories and, also, of therapeutic procedures, such as tenotomy, tendon transplantation, bone grafting, etc.

He has frankly presented his subject from a British point of view, and hopes that this example may stimulate colleagues of other countries to do the same from their national viewpoint. We sincerely hope that some American writer may take up the challenge with as entertaining and interesting a result.

The book will please the lover of medical history, will interest not only the orthopedic surgeon but the general practitioner as well. The teacher will discover much that can be used in the class room, and the student will find in "Menders of the Maimed" an interesting and logical derivation of the broad principles of orthopedic surgery. Would that more scientific books were written in as interesting and scientific a style.

INDUSTRIAL NURSING for Industrial, Public Health and Pupil Nurses, and for Employees of Labor. By Florence Swift Wright, R.N., Bureau of Child Hygiene, New Jersey State Department of Health; Formerly Secretary of the Benefit Association of the Employees of John Wanamaker, New York; and formerly in charge of Industrial Nursing for both the Cheney Brothers Silk Mills and the Clark Thread Company.*

Procedures in industrial nursing must of necessity be flexible. Modification is required as each industry presents a separate problem, and future industrial and social development must be provided for. Certain standardizations, however, in methods, records, and equipments will make for efficiency.

In the preparation of this work Miss Wright has drawn upon the experience of many industrial and public health nurses and she has appended a list of the sources of information and a general bibliography which will be of great value to nurses in this field or to employers instituting nursing service. Usually a department of nursing is introduced into an industry for a specific purpose, and its scope depends upon the department in which it is engaged. This work indicates what need be looked for in personnel, and the possible scope of its activities.

Chapters are devoted to the development of industrial nursing; the qualifications and training of the industrial nurse; the principles of industrial nursing; the relations of the industrial nurse to her fellow workers, and to the community; the first aid nurse; the visiting nurse; and to details of equipment. Under "The Day's Work" and "Records and Reports" the basis of adequate records is discussed.

Where an industry is responsible for the growth and existence of a town, the activity of industrial nursing may be expanded to form what practically constitutes a nurs-

SUGAR SHORTAGE

Does it affect your infant feeding cases?

Cane Sugar as the added carbohydrate in an infant's diet can safely be replaced by

MEAD'S DEXTRI-MALTPOSE

(Malt Sugar)

without making any other alteration of the feeding formula; in fact, the change from cane sugar to Dextri-Maltose frequently results in greater gain in weight.

Mead's Dextri-Maltose is well borne by most infants. It is more readily assimilated and less liable to cause digestive disturbances than cane sugar.

If there is a shortage of cane sugar in your city, do not hesitate to try Dextri-Maltose. Most pediatricists prefer it to cane sugar.

A post card will bring literature and liberal samples

MEAD JOHNSON & COMPANY, Evansville, Ind.

SUPPLEMENTAL FOOD FOR INFANTS

Borden's Eagle Brand contains all the valuable proteins, carbohydrates, mineral salts and fats of fluid milk.

It is rich in fat-soluble A and water-soluble B, which McCollum and other investigators have demonstrated are indispensable to the normal growth and well being of the young.

Borden's Eagle Brand consists entirely of pure milk and sugar condensed together in definite proportions. It is easy to digest and assimilate and offers a nourishing, body-building food that physicians can prescribe with perfect assurance as a complete infant diet or as a supplemental food for the breast fed infant.

Samples, analysis and literature on request.

ing center, in which event special training from the social viewpoint may be a requisite. Public Health work may be necessary; visiting nursing is desirable; pre-natal supervision, the industrial day nursery, mother clubs, and instruction in home problems may well be included in the work. The necessity is pointed out of supervision when the work of two or more nurses is definite and distinct. The work should be planned, and one person should direct all nursing and allied activities. The service may be so planned, and methods standardized as to be practically unaffected by changes of personnel.

FORCED MOVEMENTS, TROPISMS, AND ANIMAL CONDUCT. By Jacques Loeb, M.D., Ph.D., Sc.D., member of the Rockefeller Institute for Medical Research.*

Loeb undertakes in this book an analysis of the mechanism of voluntary actions on the assumption that all these motions are determined by internal or external forces. Motions caused by light or other agencies may appear to be an expression of will and purpose on the part of the animal, but in reality consist of "forced movements," according to Loeb. Forced orientation by outside sources of energy is called tropism; hence forced movements are designated "the tropism theory of animal conduct."

In the first three chapters Loeb re-states his well known theory. Succeeding chapters report further experimentation, mainly with lower animal forms. Seven different types of such movements are discussed, his greatest emphasis being placed upon heliotropism.

The chief importance of this contribution is the mechanical basis his work argues which would classify the wonder and mystery of instinct as an acquired instead of an hereditary trait.

"The theory of tropisms," he says, "is at the same time the theory of instincts if due consideration is given to the role of hormones in producing certain tropisms and suppressing others." Even the manifestations of associative memory he explains from the viewpoint of the physicist rather than that of the psychiatrist. "The influence of an associative memory is exactly measurable," he says, and, moreover, "what we call a memory image is not a 'spiritual' but a physical agency. We therefore need not be surprised to find that such memory images or 'conditioned reflexes' can vary and multiply the number of possible tropistic reactions." These interpretations are of the utmost importance to psychology. They are not in accord with the generally accepted view among scientists as to the inherited nature of the instincts, and call for a systematic analysis of instinctive reactions from the viewpoint of the theory of tropisms.

DYNAMIC EVOLUTION. A study of the Causes of Evolution and Degeneracy. By Casper L. Redfield.†

The mere fact of heredity by successive stages does not explain to Redfield how human intelligence was derived from man's ancestry nor man's increase in dynamic power. These differences he attributes to energy potentials and assumes that work done may produce accumulated energy which may be transmitted.

The power of trotting horses to "breed on" he considers due to the fact that accumulations of energy persist through several generations. Animal energy behaves

What About the Sleeping Habits of Your Employees?

Industrial Welfare Workers, Efficiency Men and Employers of Skilled and Unskilled Labor Are Now Giving the Subject of "Sleep" the Attention It Deserves

THE efficiency value and importance of restful "sleep" is now being more and more appreciated by employers of every kind of labor.

In the past the qualifications of prospective employes were gauged almost entirely by their former records of service, habits of living, habits of thrift, physical appearance and estimated capacity — without a word or thought about their habits of sleep.

Investigations of serious-minded Welfare Workers in large industrial plants, however, have demonstrated over and over again that employes who live properly and get nine good hours of refreshing and restful sleep attain the greatest degree of efficiency in their various occupations.

Public Health Officials and Welfare Workers have already accomplished splendid results in spreading the gospel of pure air, proper housing and improved working conditions for workers everywhere. Their work is now being further supplemented by

deserved thought, attention and educational effort in encouraging more sleep and better, more sanitary sleeping conditions for the individual workers.

For pure air and a comfortable bed in a sleeping room are necessary to personal efficiency—just as pure air, modern equipment and safety devices are necessary to best efforts in the mill, factory or office.

But sound sleep isn't obtained in a bed that rattles or squeaks or that shocks the nerves into semi-wakefulness by unusual slippings of the springs or unexpected creakings of its parts. For this reason, the modern, sanitary, rigid and noiseless Simmons Steel Bed equipment is the choice of up-to-date Hotels, Hospitals, Schools and Industrial Dormitories just as it is the choice in thousands of homes.

Timely and helpful data regarding the important subject of sleep, together with our complete catalog of Beds and Sleeping Equipment will be mailed promptly upon request. Address,

(Continued from Adv. Page 26)

in concentration and dissipation in a manner similar to heat and electricity, and he considers it highly probable that, in the same way they have been evolved for heat and electricity formulas for energy potentials may be constructed, which can be applied to different animals in a pedigree. His studies are made from pronounced and well recorded illustrations in trotting horses.

In men he investigated the form of energy which produces mental power and mental characteristics. By dividing a large group of intellects into groups by the ages of their fathers, the group represented a graduated scale, the intellectual grade of the children representing the intellectual grade of the parents at the time the children were conceived. The average age of the fathers of the especially great men from different countries and of different races, was approximately fifty-five years, from which he deduces that work done stores accumulated energy which may become an ordinary character and be transmitted. "If successive generations are active, then that activity concentrates in proportion to the degrees of activity and the length of time employed, and we have steadily increasing mental power, as in man. . . . The same processes are in operation today, and a knowledge of what they are and how they operate will enable him to utilize them as he will."

All of which is an interesting theory and makes fascinating reading but it involves the transmission of acquired characteristics, and hence cannot be considered good biology.

THOUGHTS OF A PSYCHIATRIST ON THE WAR AND AFTER. By William A. White, Superintendent St. Elizabeth's Hospital, Washington, D. C.*

Recent years have seen the evolution of psychiatry from the treatment of the limited concept insanity to its application in the restoration of imbalances of the personality make-up and defects in adjustment. In this book the psychiatrist has sought for the psychologic principles involved in the personal and social readjustments necessary after the great war. Mankind has not changed over night, he says, and the beginning of these changes have for years been taking root all about us and reach in their origin to instinctive springs of human conduct.

He draws a very complete analogy between the psychologic traits and the psychic evolution of the individual and the psychic reactions of the social group.

The human animal has certain fundamental instincts which it spends its life endeavoring to satisfy. The individual is said to be integrated when each instinct or activity is properly subordinated to the service of the whole organism. "When any one instinct is enabled, for any reason, to gain the mastery of the whole organism, so that it dominates its activities, that individual is sick. . . . It is the same with the social organism."

If any single group comes to dominate the activities of the whole social organism, it, too, would be sick. An exceedingly important aspect of the process of integration is that integration in itself is a process of development, and failure of integration is an indication of relative immaturity. All forms of abnormal or antisocial conduct we are coming to see as ways of expressing instincts which are relatively undeveloped. They are subject to repression or diversion into channels which are socially useful. We must learn to see individuals, races, species as but reactions of adaptations, more or less successfully

(Continued on Adv. Page 30)

The nutrient value of Virol illustrated in a series of cases, particulars of which have been supplied by medical men.

CASE 1

BABY UNDERWOOD was so wasted that he had to be wrapped in cotton wool and carried on a pillow.

Before VIROL

After VIROL

THE DOCTOR ORDERED him to be fed on Virol, upon which he regularly improved until at 13 months old (see second photo) he weighed 22 lbs, 6 ozs. Children brought up on Virol have firm flesh, strong bones, and beautiful color. Palatable in flavor—children love it.

MALNUTRITION—Virol is a dependable nutrient and reconstructive in all wasting conditions, in tuberculosis, anaemia, gastric ulcer, rickets, scurvy and all strumous conditions.

Virol is rich in the food accessory substances known as vitamines, and especially in the fat soluble vitamine. Recent feeding experiments have shown the important part played by these vitamines not only in development and growth and in the prevention of rickets, but also in raising the power of resistance to diseases of bacterial origin.

Used in more than 2,000 hospitals, sanatoria, and infant clinics in Great Britain.

Sole Agents for U. S.

ETNA CHEMICAL COMPANY, 59 Bank Street, New York

Virol is a valuable food for invalids and children. It is a preparation composed of Red Marrow, extracted from ox rib and calves' bones by C. P. glycerine; refined Marrow and Beef Fat; highly diastatic Malt Extract; Eggs; Lemon Syrup and soluble Phosphates.

In glass jars: 50e, \$1.00 and \$2.00.

Liberal samples and interesting literature sent to physicians on request.

Best Fitted to Digest

Puffed Wheat and Puffed Rice are whole grains steam exploded. Corn Puffs are corn hearts puffed.

The process was invented by Prof. A. P. Anderson, formerly of Columbia University. The object is to blast all food cells for easy, complete digestion.

Ordinary cooking breaks part of the food cells. This process breaks them all. And it makes grain bubbles, thin and flimsy, with a delicious taste.

These delightful grains, cooked, toasted and exploded, are the best-cooked cereals in existence.

integrated, to meet the problems which have confronted them.

Societies have become more and more complex. The interdependence of the several groups has been recognized and each properly subordinated to the interest of the whole; but in war time all those instincts and impulses of a self-seeking nature which ordinarily are repressed or held in check by the group are uncovered and become operative. Neuroses which in peace are crippling only to the individual lead to overt acts of concrete indulgence. Reason seems temporarily dethroned and pure feeling, emotion, takes its place as the motive force of conduct. Hate, fear, and other repressive traits constitute the emotional reactions of war.

He goes on to analyze from the viewpoint of the psychiatrist the causes of war and the various factors at work as a result of the war which make for a democracy of equal opportunity. The mutual distrust of men in different walks of life based upon their ignorance of each other tends to disappear.

The ever present conflict is between socialism and individualism. A reaction to either extreme is destructive. A compromise,—rationalization,—must be effected. It is the great opportunity to turn these enormous energies into channels which shall effect constructive ends, into activities which shall be useful in the largest sense. Certain attitudes of mind must be modified. Hate is far more destructive to those who indulge in it than to those upon whom its force is expended. When men can realize that they all are after the same things, that growth is in the same general direction for all, they will come to realize that they can better effect their several purposes by pooling their interests than by insisting too strongly upon individual recognition. The difficulties of adjustment are stupendous. New standards must be formulated, higher integrations evolved, and a better coordination of activities achieved for the common good of all.

THE FUTURE OF MEDICINE. By Sir James Mackenzie, F.R.S., M.D., F.R.C.P., LLD.AB. & Ed., F.R.C.P.L., (Hon.) Consulting Physician to the London Hospital.*

The whole book is an argument for a more scientific basis of medical research, a warning against certain present tendencies to place implicit trust in mechanical laboratory methods, to the neglect of the subjective symptoms, and is a plea for the consistent training of the clinician who ties up the physical findings with the actual observation of the patient so as to assess the real value of any given symptom.

With the premise that "if a problem is to be solved the nature of the problem and its difficulties should first be comprehended," Mackenzie undertakes a review of the medical situation as it stands today.

"Medicine has advanced so far," he says, "that for the study of disease after the patient has died, we find institutions magnificently equipped, presided over by men of great experience and training; for patients suffering from the advanced stages of disease, we have great hospitals, with staffs of skilled physicians, surgeons, and specialists. If we seek to find out what are the facilities for the detection and cure of disease in the stage when it has not damaged the tissues, we discover that little consideration is given to this aspect of the matter. . . . Few or no attempts are made to train men for the detection of disease when there is hope for cure." The surgeon, accord-

STERLING

Therapeutic Lamp

"The Light That Heals"

Has proved one of the most efficient methods of relieving pain; its effect is soothing and analgesic; its rays are germicidal. The warm, soothing, soft rays penetrate and vitalize every cell and tissue, new cell growth is stimulated; the

body is refreshed and vitalized.

In rheumatism, neuralgia, neuritis, lumbago, in nervous conditions and a score of other symptoms and diseases, including skin and scalp disease, the Sterling Therapeutic Lamp is invaluable for the relief from pain, inflammation and for corrective purposes.

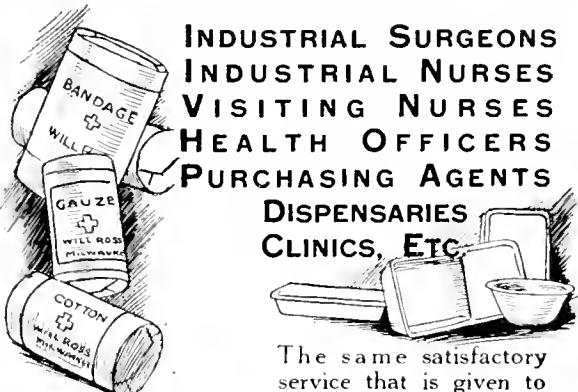

Scientific—Efficient—Economical

With stand it is ideally adapted for additional use as a spot light for operations and examinations as illustrated. Widely used in sanitariums, physicians' offices and hospitals; special sizes are adapted for the use of patients under the supervision and direction of the family physician.

Write for our interesting Illustrated Booklet showing the various sizes and uses of the Sterling Therapeutic Lamp.

BOOKS OF THE MONTH

(Continued from Adv. Page 30)

ing to his thesis, may be said to flourish on the failures of the clinician.

Graphic comparison is made between the causes for which 1,000 consecutive patients sought medical advice and the causes of deaths in England and Wales in 1912. Evidently the diseases that weaken the community are not those of which the people die. "The progress of medicine has had little effect in preventing the occurrence of the most common diseases." To achieve the aim of medicine, disease must be recognized early, and all phases of its life history must be observed. Manifestly the only person who can do this is the general practitioner.

The complaint is made of medical education that it has an imperfect conception of the aim of medicine. The student is trained in methods needlessly complex. The dominant idea today leads one to depend upon the revelations by some mechanical contrivance devised in the laboratory of the signs of disease which can be detected only by the trained senses of a skilled examiner. The idea of specialism dominant today darkens the understanding with a cloud of detail and under this conception the vast bulk of suffering humanity can never get adequate attention.

The next thing the discoverer of a mechanical device has to do after he has recognized its use in clinical medicine is to get rid of it in practice and by research, according to the "Law of Associated Phenomena" the immediate objects are to discover (1) the mechanism of the production of a symptom, and (2) the determination of what bearing its cause has on the patient's future.

Application of these principles is made to the clinical researches of the author in affections of the circulatory system. As well qualified as any at the outset of his medical career, he soon found himself unable to recognize the maladies in many of his patients. In the main they presented no gross physical signs, and he was unable to appreciate the subjective symptoms, and for most of these problems he found no help in the literature. Details of a systematic investigation of the patients' sensations are set out in chapters on "The Investigation of Pain," "Irregular Heart Action," "Auricular Fibrillation," and "Observation on the Effect of Drugs," work which constitutes the basis for accepted procedures in heart conditions.

Generalizations from these special studies are drawn in succeeding chapters which suggest similar principles of research in other fields. The book is a very thoughtful consideration of many phases of the practice of medicine. Without incriminating any one person or any school, he holds that present conceptions of medicine are subject to revision if medicine is to evolve as a precise science.

The work reported is of the utmost value. When all is said, the method is the man. The man whose interest in his work and concern for his patient leads him consistently over a period of twenty years to amass records, train his sense perception, and correlate findings is the man upon whose clinical judgment it is safe to rely, and the type of general "practitioner" and "teacher" too rarely encountered. In the hands of such men the "Future of Medicine" may be safely entrusted.

Favorable Health Statistics

The health statistics of the principal cities of the United States and for the leading insurance companies show that the mortality has been lower and health conditions have been more favorable during the past summer than during any corresponding period in recent years.

THE PREVENTION OF THROAT IRRITATION

IN these momentous days when public speaking is so general among thoughtful people, medical men have been quick to recognize the value of a good, pure chewing gum for alleviating the dry mouth and irritable throat that cause so much discomfort and annoyance to the majority of speakers.

Practical experience has shown that chewing gum not only exercises all the muscles of the mouth and throat, making them extremely flexible and responsive, but it also stimulates a natural flow of saliva, thus soothing the throat and keeping the mouth from becoming dry and parched.

It is common knowledge, moreover, that the use of chewing gum for a few minutes before speaking also relieves nervous tension and helps to put the speaker at his ease.

Physicians who lecture a great deal, or who give clinical instruction while operating, will find chewing gum a real boon. It is always available, it is pleasant to use, and it is prompt and effective in its results.

For years Adams Pure Chewing Gum has stood for the standard of quality.

Physical Conditioning

So many patients, especially women, lack the initiative to follow general advice regarding exercises, dietary, and personal hygiene. Physicians acquainted with my work are constantly referring these cases to me for physical and mental "conditioning."

A woman can often inspire her sex to be and to do and hold her to this inspiration by regular correspondence as men cannot.

Every pupil's requirements are studied individually, and each is directed according to her needs and her strength.

This cooperative work with the medical profession is giving results highly gratifying to both physicians and patients.

I shall be glad to assist you with patients who need conditioning through exercise, diet, breathing, correct poise, relaxation, reduction of flesh, or building of flesh.

COMMITTEE AIDS CHILD PARALYTICS

The New York Committee on the After Care of Infantile Paralysis Cases states in its annual report that it took care of 8,253 cases during the past year. All have shown great improvement and many have been permanently cured. A survey now under way indicates the necessity of complete records of cripples, additional clinics, increased means for transportation, and the development of field agencies to help those in need of orthopedic assistance.

Military Surgeons Elect Officers

Officers chosen by the Association of Military Surgeons of the United States at its annual meeting in St. Louis, October 13 to 15, are: president, Lieut. Col. Joseph A. Hall, M.C., O.N.G., Cincinnati; vice-presidents, Assistant Surgeon General John W. Kerr, U.S.P.H.S., Washington, D. C.; Capt. Frank L. Pleadwell, M.C., United States Navy, Washington, D. C.; secretary-treasurer-editor, Col. James Robb Church, M.C., United States Army, Washington, D. C. The next meeting will be held at New Orleans the three days immediately preceding the meeting of the American Medical Association.

THE AMERICAN JOURNAL OF NURSING

In the November issue of the *American Journal of Nursing* the members of the nursing profession are criticized editorially for inertia in matters vitally concerning their work. Nursing organizations are charged with leaving discussions and decisions to other hospital officials, without adequate activity on their own part. The rank and file of nurses are urged to rise to their present opportunities.

The nursing question is a most absorbing topic, their training, the situation in New York, and rank for nurses, forming the basis for editorial comment. In the same journal Isabel M. Stewart, R.N., discusses the readjustment necessary in the training school curriculum to meet the demands of public health nursing. She considers that such additional courses should be limited to those who show fitness and who intend to follow public health work for a year or two. The hospital should concentrate more on what the public health nurse needs, and ward teachers should emphasize ward experience. The whole matter is to be the subject of a special study by the Rockefeller Foundation.

Social work on the part of a nurse in China is emphasized by Nina D. Gage in an article on "Stages of Nursing in China." As sickness is considered by the Chinese as one form of punishment for sin, even nursing care may be considered as interfering with Divine plans.

The tie-up between nursing care and religion was not easily broken for the early English hospitals were evangelistic and the same deaconesses nursed, cared for orphans and prisoners, and did evangelistic work. The regeneration of nursing in China came from physicians, and the first nursing schools were established by women physicians in 1873. The progress of the profession is traced to the present time, and its needs urged upon the nurses of America.

Other articles are: "Standard Curriculum," by Isabel M. Stewart, R.N.; "What a Nurse Should Know About Syphilis," by Herman Goodman, B.S., M.D.; "Enlarged Thymus Gland in Infants," by Constance Bull, R.N.; "The Need for More Tuberculosis Nurses," by Mary A. Isenberg, R.N.; "Mobile Hospital No. 1 in France," by Ida M. Anderson, R.N.; and "Student Body Government," by Clara C. Rue.

PURE, POTENT AND PRACTICAL

Neosalvarsan

Trade Mark Reg'd U.S. Pat. Off.

(NEOARSPHENAMINE-METZ)

Is as pure and potent as the imported product.

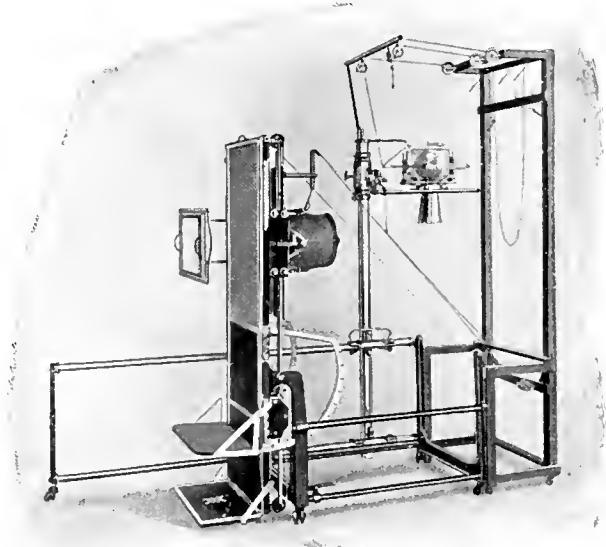

NEOSALVARSAN immediately dissolves in room-temperature water, (68°-77°F) and can be injected by means of a 20 to 50 c. c. glass syringe.

WHEN PROPERLY ADMINISTERED, NEOSALVARSAN does not cause reactions.

Most dealers have a stock on hand. Extra discount when purchased in lots of ten or more ampules.

H. A. METZ LABORATORIES, Inc.,
122 HUDSON STREET

For Group Clinics—For Industrial Hospitals

When you are interested in an x-ray equipment representing the most advanced ideas consistent with conservative practice, to facilitate and expedite your work, then investigate a Meyer equipment.

MULTOSCOPE, a stereo-radiographic table with tube holder and radioscope for vertical, horizontal and inclined position, with self-contained aerial and high tension switch.

KLINOSCOPE, a fluoroscopic apparatus for vertical and horizontal fluoroscopy.

TRANSFORMERS, with a marked efficiency and conservation of tubes.

DUPLEX STEREOSCOPE, enabling the surgeon and roentgenologist to observe the view at the same time.

A competent installer and service man for every installation

THE WM. MEYER CO.

1644 N. Girard Street CHICAGO, ILL.

Is the very best cleanser for COFFEE POTS and COFFEE URNS, quickly and thoroughly cleaning them and making them as good as new.

It also cleans URN SACKS with the same thoroughness, taking out all the stale coffee odors. Do not use soap with the Solvent when cleaning metals.

Scrubbing and scouring mean wear and injury of surface and fabric.

In cleaning anything the ideal way—avoiding injury and saving labor—is to apply a cleaner which will loosen the dirt and grease without harm to the hands.

ARISTON MAGIC SOLVENT

does just that. It dissolves grease and dirt, removing them without scrubbing or scouring; without laborious effort; without injury to the goods or hands and with much better results than can be obtained in any other way.

Only a spoonful to a pail of water—that's the proportion for general uses. A 5-lb. package lasts a long time and does a lot of work.

Send us a dollar and we'll ship you a regular 5-lb. carton. We do not pack in larger bulk, because the Solvent is to be used sparingly.

CALUMET TEA & COFFEE COMPANY

409-411 W. Huron St.

Chicago, Ill.

AMERICAN SOCIOLOGICAL SOCIETY MEETS IN CHICAGO

The annual meeting of the American Sociological Society will be held in Chicago, December 29 to 31, 1919, in conjunction with the meetings of the American Economic Association, the American Statistical Association, and other organizations.

The general subject for discussion at the annual meeting will be the problems of democracy. The meetings will be devoted to addresses, papers, and discussions of democracy in its various angles of contact and their purpose will be an attempt to establish a program for the realization of a working democracy in the world, particularly in the United States.

NEW JERSEY SANITARIANS MEET

The forty-fifth annual meeting of the New Jersey Sanitary Association was held at The Laurel-in-the-Pines, Lakewood, N.J., December 5 and 6.

One of the important subjects taken up was an address on "The Underlying Causes of the Narcotic Habit," by Alexander Lambert, M.D., New York, President of the American Medical Association.¹

Public health occupied a prominent place on the program, one of the topics being "The Future of Public Health Legislation in New Jersey," and another, the "Development of Public Health Nursing During the War and Reconstruction Periods." Other subjects discussed were "The Application of Rehabilitation Methods from War to Civil Life," "Milk Control."

CHICAGO HAS NUTRITION CLINIC

The Institute on the Nutritional Problems of Children, given in Chicago, Nov. 10 to 22, 1919, under the auspices of the Elizabeth McCormick Memorial Fund, was received with great enthusiasm and serious thought.

Dr. Wm. R. P. Emerson, M.D., of Boston, and his head chief clinical director, Miss Mabel Skilton, conducted a class for the student nutrition worker to prepare these workers to go into this branch of modern medicine. The intensive two weeks' program included class work daily training the student to keep daily diets for the children in the various schools where such clinics are held.

Class discussions included: (1) description of a nutrition clinic and class; (2) identification of malnourished child; (3) physical, mental, and social examinations and history record; (4) class procedures and methods; (5) cooperation at home and school; and (6) the nutrition worker.

Doctor Emerson followed the work by giving physical examinations and lectures to the various groups of people,—teachers of home economics, social service workers, nurses, welfare workers, the pediatric society, the Chicago Medical Society, the Woman's Medical Society, and various other gatherings.

This work has brought to the minds of many of the people doing social work the fact that the malnourished child must be taken care of from the same standpoint as the child that has various other diseases. The students represented many branches of work. The physician, the welfare nurse, field dietitians doing social service dietetics in clinics, hospital dietitians, nurses in child-caring institutions, and visiting housekeepers, were represented.

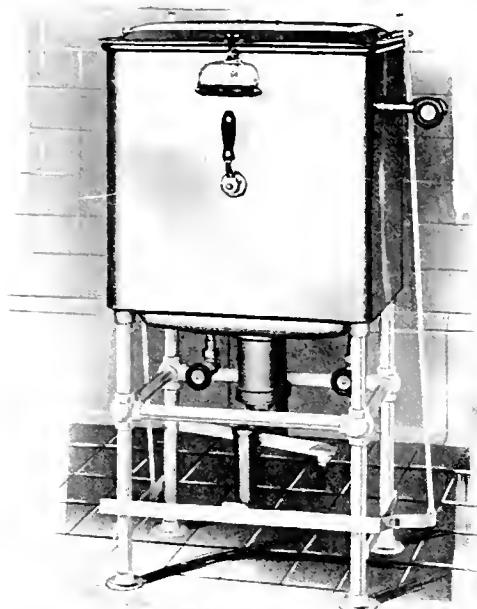

A program to be carried out in various dispensaries of Chicago as the direct outcome of this course given here will be reported in future issues of MODERN MEDICINE.

¹ This article will be published in an early issue of MODERN MEDICINE.

"AMERICAN"

THE PRODUCT OF SPECIALISTS

BUILDINGS versus EQUIPMENT

Bed-Pan Sterilizer and Washer
Dumping Type

The reputation of an institution does not depend so much upon the character of the buildings that house it as upon its PERSONNEL and its WORKING EQUIPMENT.

Beyond a certain point anything that may be added to the exterior becomes an embellishment—beautiful but not VITAL.

Proper sterilizing equipment is vital.

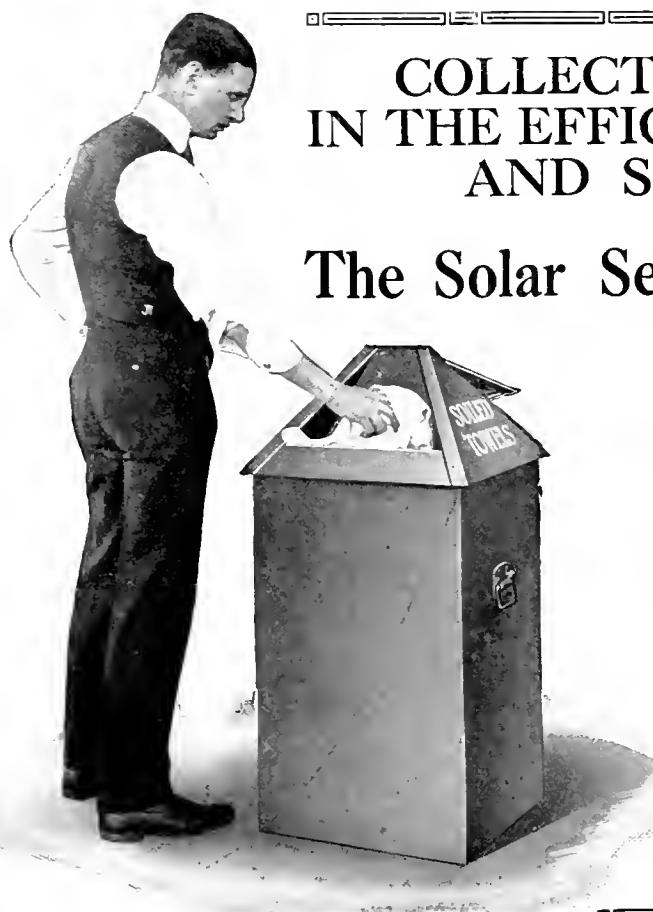

Next in importance to the human element in any undertaking are man's mechanical aids. Doubly so is this true of the Surgeon's work.

"AMERICAN" sterilizers are built to be worthy of this important role. DEPENDABLE, EFFICIENT and EASY OF OPERATION—they have gained the front and have kept it. Investigate "AMERICAN" sterilizers and you will find that the secret of their success is HIGHEST QUALITY and LONGEST SERVICE.

AMERICAN STERILIZER COMPANY, Erie, Pa.

COLLECT SOILED LINENS
IN THE EFFICIENT, ECONOMICAL
AND SANITARY WAY

The Solar Self-closing Waste Can

The inside sack, when filled, is lifted out and replaced with an empty one. The filled sack and contents are carried to the laundry. The collector is always in service—removals are prompt and complete.

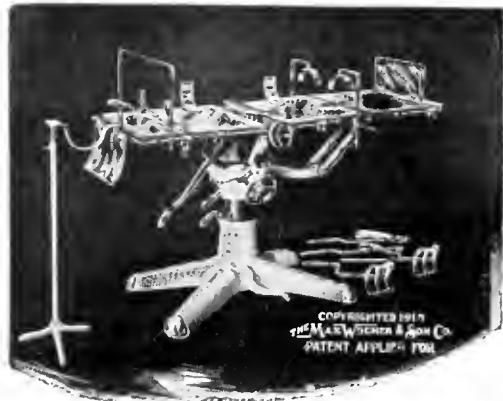

Strongly made of steel and attractively finished in oven-baked, durable and cleanly enamel.

AMERICAN CHILD HYGIENE ASSOCIATION

The Tenth Annual Meeting of the American Child Hygiene Association which was held at Asheville, N. C., November 11 to 13, 1919, was a conference between representative workers in child welfare all over the United States, and was characterized by an intensive study of the special problems involved.

Maternity problems and prenatal care came up first for consideration. The relationship between the decrease in the general death rate and the special death rate in children under one year, on the one hand, and the stationary position of the infant death rate during the first few weeks of life, Dr. Merrill E. Champion considers a matter of the greatest concern for public health officials. He believes that some sort of maternity benefit would aid in reducing infant and maternal mortality.

The symposium on infant feeding was led by Dr. J. P. Sedgwick, of Minneapolis. That it is the task of the expert to think out the problem of help in the home for the mother with a young baby, was the dictum of Dr. Helen MacMurchy of Toronto. The organization of the home is the concern of the state, she says, and it is quite possible to change the occupation of the homewoker into a new and attractive profession for women.

A historic perspective of child hygiene campaigns by Dr. John A. Foote, Washington, D. C., gave evidence of lay interest in legal enactments of this character in the second century. Popular treatises on matters of child hygiene by Soranus, of Ephesus, lack little of modern interest. Anius Qellius argued in the second century in Rome for maternal nursing; but all traces of altruistic work were lost in the bloody years after Marcus Aurelius.

Reports of activities were made by Sara B. Price, superintendent Child Welfare Society, Chicago, from the viewpoint of the city. Rural service was discussed by Virginia Knox Kimble, state supervisor of nurses, Topeka.

The work in nursing and health of the university extension service, Columbia, Mo., was the subject of the discussion led by Mrs. Louis Selbert, of the University of Missouri.

Government work in England and Scotland for children of pre-school age was shown by Dr. Wm. Palmer Lucas, San Francisco, chief of the Children's Bureau of the American Red Cross in France, to provide day and night nurseries for workers. The medical supervision of the health of all children under five was assumed by the Public Health Authority. Toddlers' play grounds and wards for ailing children were included in the health center activities.

Correctable defects under six years of age and suggestions for follow-up work as indicated in San Francisco formed the basis of the contribution by Dr. Adelaide Brown.

Nor was the health significance of developmental traits of character overlooked. P. A. Surgeon Walter L. Treadway, United States Public Health Service, Washington, D. C., urged psychiatric analysis of the whole personality and development as the rational basis of the new preventive medicine.

Under specific problems in rural districts, the following topics were treated:

Rural, Dental, and Surgical Clinics. Dr. George M. Cooper, Director, Bureau Medical Inspection of Schools, North Carolina State Board of Health, Raleigh. Opportunities of the Rural Public Health Nurse for Developing Child Hygiene. Mrs. Ruth A. Dodd, South Carolina State Board of Health, Columbia. The Minnesota Rural Clinics. Dr. E. J. Hueneckens, Minneapolis.

Cafeterias and Lunch Rooms Are Common Sense Health Insurance

The physical and mental well-being of employes are important factors in the efficiency of every industry. Faulty nutrition is recognized as a detrimental condition for the satisfactory progress of school children, as well as preventing 100 per cent service from the employe. Properly conducted Cafeterias have proved their worth in bringing the individual up to par in both industries and schools.

Rest and Club Rooms, considered essential by many employers, add that element of good-will necessary for the complete co-operation of the employe.

As the largest Cafeteria and Lunch Room Equipment house, we are prepared to design a Cafeteria or Lunch Room to meet any special needs, or to advise on correct equipment and installation. Regardless of what is required, we can supply it—at a saving. We furnish everything for Rest Rooms or Industrial Clubs at a saving to you of time and money.

Successful installations all over the country testify to our ability in these lines. Let us assist you in the formulation of your plans.

Write for This Special Literature

Book G10—Lunch Room Book—Containing complete data on industrial Lunch Room installations.

Book G40—Rest Room Book—The whole story of the Rest Room.

Book G60—Employment Betterment—The story of what industrial welfare work means in actual results.

Always Ready for Immediate Use

Puerperal Sepsis

Hyclorite irrigation in puerperal sepsis is a positive aid in controlling infection and stopping discharges and odors without irritating the mucous membrane.

Even in high dilution, Hyclorite destroys toxins, thereby permitting the temperature and pulse to return to normal promptly.

It is a valuable adjunct to the physician's obstetric case because it is always ready in any emergency.

HYCLORITE

Concentrated Sodium Hypochlorite

Hyclorite requires no testing.
It is always ready for use.
Just add water and apply.
No waste. No waiting.
Non-irritating properly diluted.

Price, 32-oz., \$1.25

BOSTON HAS BABY HYGIENE EXPERTS

The work of the Boston Baby Hygiene Association which cared for 7,000 children during the past year at twenty stations in various parts of the city was the basis of considerable study and discussion at the tenth annual meeting of the American Child Hygiene Association at Asheville, N. C., in November. In recognition of its splendid work, six Boston physicians and four Boston women were assigned prominent parts in the conference.

JOURNAL OF DENTAL RESEARCH

The September number of the *Journal of Dental Research* testifies to the awakening of interest on the part of physicians in dental problems. There was a time, and that time is not so very long ago, when the dental profession was entirely divorced from the medical profession. The dentist considered himself a specialist in an isolated part of the human body, which has no connection with any other parts of the organism. The physician, on the other hand, considered the dentist a mere mechanician, who cements decayed pulps, and pulls diseased roots. Times have changed. The dentist realized that the teeth are only a part of a complex organism, and that it behooves the man who is concerned with the ailments of human teeth to study also the ailments of other parts of the body. The physician also broadened his scope of thought in connection with dentistry. He realized that the teeth may and do influence other parts of the human body, and it is a mistake to leave the osseous part of the buccal cavity out of consideration.

This interchange of interests is strongly noticeable in the third number of the *Journal of Dental Research*. Both physicians and dentists meet on common ground. Of considerable interest is the article by E. E. Rosenow on elective localization of bacteria. As is well known, Rosenow has for years promulgated the idea that certain bacteria show preference for certain parts of the body. In this paper, Rosenow applies his work to dental foci, and shows that with more delicate methods it can be demonstrated that bacteria from dental foci of infection localize in certain parts of the body and set up various lesions in those parts. These observations lead him to a number of practical suggestions. The wholesale devitalization of teeth, and the filling of infected root canals without due regard to asepsis, according to Rosenow's research, result in the formation of apical infections and in much ill health. Of still greater clinical importance is the conclusion reached by Rosenow that "Tonsillectomy as now so commonly practised before the condition of the teeth has been corrected is illogical. The lymphatics of the mouth and jaws drain into the tonsils. Some infections of tonsils improve or even disappear following the extraction of infected teeth." This advice is of vital importance in view of the general practice of removing hypertrophied tonsils without taking into consideration the source of infection causing the enlargement of the tonsils.

An interesting contribution in the same issue is that of H. A. Cotton, who was able to trace mental disturbances to infected or impacted teeth. He cites cases of patients that came under his observation, with marked mental symptoms, and whose minds cleared up after the offending focus of infection was removed from the teeth. This opens a new line of thought in psychiatry, a field that is well worth investigating.

The Journal contains several more interesting contributions that are of value to the physician and dentist alike. If the *Journal* continues to present such interesting material, the gap between the physician and dentist will soon be bridged over.

Surgical Wax

Alleviates Pain

When the wax film is laid on a denuded surface the patient is relieved of pain immediately.

Until after the healing process has started, Stanolind Surgical Wax should not remain on the wound longer than twenty-four hours.

Later the wound may be cleansed and redressed every forty-eight hours.

In removing the dressing, when that portion adhering to the uninjured skin has been loosened, the entire film may be rolled back without causing the least pain, or without injury to the granulations.

Stanolind Petrolatum

For Medicinal Use

in five grades to meet every requirement.

Superia White, Ivory White, Onyx, Topaz and Amber.

Stanolind Petrolatum is of such distinctive merit as to sustain the well-established reputation of the Standard Oil Company of Indiana as manufacturers of medicinal petroleum products.

You may subject Stanolind Petrolatum to the most rigid test and investigation—you will be convinced of its superior merit.

Something to Keep on Hand!

The uses of 20 MULE TEAM BORAX are so diversified as to prohibit complete enumeration here.

Every hospital needs it in the sick room, in the laundry, in the kitchen—for use in douches and washes, for cleansing bedding, clothing, table linens and dishes, to remove every vestige of dirt from floors and woodwork, and for the toilet and bath.

20 MULE TEAM BORAX is surprisingly effective in routing dirt and germs, yet it is harmless and non-irritating to the most delicate skin or the finest fabric.

20 MULE TEAM BORAX is a necessity. Why not order a large package today? Your dealer has it.

Pacific Coast Borax Company
New York Chicago San Francisco

SCHOOL OF HEALING BY OCCUPATION

The School of Occupational Therapy, the only institution of its kind in the state of Pennsylvania, opened October 19, in Philadelphia. Its purpose is the training of aides in the new profession of "healing by occupation." There are courses in weaving, stenciling, block printing, modeling, book-binding, wood carving, toy making, and basketry.

Through cooperation with the Philadelphia General and the Pennsylvania Hospitals the work in occupational therapy is supplemented by hospital training under skilled supervision and by a course of lectures by eminent physicians, surgeons, and psychologists.

THE SURVEY

The issue of *The Survey* under date of November 15 contains an analysis of the International Labor Conference by Wm. L. Chenery who considers that, notwithstanding the uneven acceptance of general rulings of existing organizations, a powerful influence for progress is indicated in the call of all governments before the bar of public opinion.

In "The Restoration of Civil Liberty," Richard Roberts states new tasks in defining and achieving that liberty which will enable every man to grow into his "full share of what is going on in life."

In the same issue are a report of findings of the International Congress of Women Physicians, an appraisal by Edward T. Devine of the Social Unit in Cincinnati, and a criticism of American prisons by Winthrop D. Lane.
